Keywords: Intercalation, Mg-Al LDH, cephradine, spectroscopy, SEM

Abstract. Engineered advanced functional materials are promising candidates for biotechnology and biomedical science. Mg-Al layered double hydroxide (LDH), anionic or hydrotalcite-like clays consist of positively charged layers and exchangeable anions along with water molecules in the interlayer space were synthesized from homogeneous solution of MgCl\textsubscript{2} and AlCl\textsubscript{3} by urea induced co-precipitation method. A pharmaceutically important drug, cephradine was intercalated with synthesized LDH in alkali media (pH 10) by in-situ technique. Characterizations of the products were carried out using Attenuated Total Reflectance Infra-red (ATR-IR), Energy Dispersive X-ray (EDX) and X-ray Diffraction (XRD) spectroscopy. Scanning electron morphological images envisaged a distinct crystalline and amorphous phases of Mg-Al LDH before and after modification with cephradine. Intercalation of bioactive molecules with LDH would enhance their stability providing sustained release behavior in physiological environment.

Introduction

Advanced inorganic functional materials, particularly of layered double hydroxide (LDH)-type are attracting increasing interest lately due to their versatile multifunctional applications. LDH compound consists of brucite-like sheets, in which divalent cations are partially replaced by trivalent cations [1-3]. Consequently, the layers become positively charged and the counter anions are needed to balance these charges. The counter anion can subsequently be replaced by other anions through various procedures.

Generally, the intercalation of anion can be accomplished by various routes such as direct co-precipitation [4,5] method, or exchange process [6-8]. In the former method, the LDH is contacted with a solution of the guest anion to be intercalated while in the latter method addition of a mixed M\textsuperscript{2+} and M\textsuperscript{3+} solution to a basic solution of the anion have to be done. In the rehydration method, calcined LDH is contacted with a solution containing the anion followed by aging [4]. Co-precipitation method is the most widely accepted to synthesize LDHs in which a mixed alkaline solution is added to a mixed salt solution and the resultant slurry is aged at a desired temperature. For both ion-exchange and co-precipitation methods, physicochemical and structural properties of the resulting materials depend on the precipitation pH, temperature, ageing time, washing and drying conditions [9-11]. Some reported work showed that different methods of preparation produce materials with different physicochemical properties [12,13].

Works on the intercalation of the various organic molecules into the hydroxide layers have been exploited for various purposes and application [14,15] in many different areas such as bioactive agent [10], medicine [15,16,17], catalyst [18], anti-inflammatory drugs, [19,20,21] urea biosensor and supports [22], and decolorizing agents [23]. The production and use of drug must be controlled to minimize the potential damage to the environment and public health. An effective way is to design smart formulations, which combines the optimum bioactivity and minimum amount of drug. The use of controlled release formulations of drug will restrict their movement through other
organ and prevent cross-contamination and side effects. Similarly several synthetic cationic surfactants, organic polymers, natural plant lignin and starch materials have been proposed as supporting agents for pesticides in the formulations [24]. Some studies on herbicides-intercalated Mg/Al layered double hydroxide (LDH) synthesized by direct, regeneration and ion exchange methods show slow release property [25, 26]. This is due to the fact that the loading capacity of LDH mainly depends on its charge density and layered structure. The charge density of hydroxide sheets in LDHs is in the range of 0.33 – 0.25 Cm⁻² (as high as in mica, 0.32 – 0.34 Cm⁻²) [27], which is much higher compared to that observed in various cationic clays of both natural and synthetic origin. However, the remarkable behavior of LDH is their high reactivity toward various organic anions, which can exchange as much as 80 – 100% of the interlayer anions in LDHs [27].

In this work we attempted to intercalate a pharmaceutical drug, cephradine into Mg-Al-layered double hydroxide by direct co-precipitation with simultaneous anion exchange.

**Experimental**

**Materials**

Aluminum chloride (hexa-hydrate) (MW: 241.43 g/mol, assay: 97.0%, Techno Pharma Chem, Haryana, India), magnesium chloride (hexa-hydrate), (MW: 203.31 g/mol, assay: 98.0% Uni-chem), manganese chloride (tetra-hydrate), (MW: 197.92 g/mol, assay: 99.0%, Uni-chem) and urea (MW: 60.06 g/mol, assay: 99.0%, Merck, India) were used as received. Cephradine (MW: 349.40) was purchased from Fluka and was used without further purification.

**Methods**

*Co-precipitation of Mg-Al-LDH*

LDH’s were prepared by co-precipitation from a homogeneous aqueous solution of Mg²⁺ and Al³⁺ with urea as a precipitating agent. At first, an aqueous salt solution of Al³⁺ and Mg²⁺ with the molar fraction Al³⁺/ (Al³⁺+Mg²⁺) equal to 0.33 was prepared by dissolving AlCl₃ and MgCl₂ in distilled water. To this solution solid urea was added until the molar fraction of urea/ (Mg²⁺+Al³⁺) reaches 3.3. Then the clear solution was refluxed for 36 hours. LDH was precipitated as a white mass, filtered, and washed until chloride free, and then dried in an atmospheric drier at 60°C till constant weight. Highly crystalline Mg-Al-LDH with narrow particle size was obtained. The conditions chosen for the synthesis provides Mg-Al-LDH with 'x' around 0.33, i.e. the composition is more likely represented by \( \text{Mg}_{0.67}\text{Al}_{0.33}\text{(OH)2(CO}_3\text{)}_{0.165} \cdot 0.4\text{H}_2\text{O} \) [22].

**Characterization**

*Attenuated Total Reflectance Infrared (ATR-IR) spectroscopy*

Spectra (4000-400 cm⁻¹) were collected to determine the chemical bonds of polymers after polymerization by ATR-IR spectroscopy. Attenuated total reflection (ATR) method involves pressing the sample against a high-refractive-index prism and measuring the infrared spectrum using infrared light that is totally internally reflected in the prism. A zinc selenide (ZnSe) prism is used in the ATR accessory. The instrument used was a Shimadzu Prestige 21, single bounce foundation series ATR accessory and a 45° angle of incidence. Each spectrum was obtained by cumulating 32 scans at a resolution of 4 cm⁻¹.

*XRD, EDX and SEM techniques*

The X-ray diffraction (XRD) was carried out to analyze the phase and estimate the lattice space between Mg-Al-LDH using X-ray diffractometer (XRD, Bruker D8 Advance, Germany) with 0.15405 nm Cu-Kα radiation source in the 2θ range from 5° to 70° (40 KV, 40 mA, step size 0.020, scan rate 0.50 min⁻¹). The XRD patterns with diffraction intensity versus 2θ were recorded. Energy dispersive X-ray (EDX) analysis was carried out with JEOL JSM-7600F for elemental analysis. The surface morphology of the sample was obtained using scanning electron microscopy (SEM) JEOL, JSM-7600F, Japan.
Results and discussion

Synthesis of cephradine intercalated Mg-Al-LDH

At first a procedure for synthesis of Mg-Al-LDH is established according to the published article of Vial et al. [22]. They suggested an excellent technique in presence of urea to facilitate precipitation of LDH from a homogeneous solution of MgCl₂ and AlCl₃ salt with refluxing 36 h. The synthesis conditions chosen for Mg-Al–LDH provide with the compositional formula which is expressed by Mg₀.₆₇Al₀.₃₃(OH)₂(CO₃)₀.₁₆₅·⁰·₄H₂O [22].

Since the cephradine consists of one carboxylic acid functional group, an aqueous alkali medium (pH 10) was chosen to activate the functional group as –COO⁻Na. Besides, this drug also contains two more carboxyl functional group which presents the molecule as a negatively charged candidate for the positively charged Mg-Al-LDH. Primarily, we tried to intercalate the drug only stirring the mixture of the solution at pH below 7, unfortunately there was no trace of intercalated drug in the LDH compound checked by different instrumental means. This is due to the fact that in acidic pH, cephradine is protonated and becomes positively charged entity which was strongly electrostatically denied by cationic LDH as shown in Fig. 1. Therefore, we changed our way to intercalate the drug and followed an in-situ intercalation process in alkali environment. Cephradine at pH >7 becomes soluble in carboxylate state but due to loss of protons, nitrogen atoms of amines exist with pair of electrons which attract positively charged metallic ions of LDH.

ATR-IR spectral analysis

ATR-IR spectroscopy has been used as an important tool for characterizing molecular structure of cephradine in terms of functional groups by studying the vibration change occurring from the excitation of the bonds. In LDH, ATR-IR is used to determine the presence or absence of target molecules in the interlayer, and to check that LDH layered material matches the expected spectrum. Since functional groups absorb at characteristic frequencies of IR radiation, ATR-IR with higher-quality scans was performed to find detailed information (c.f. to specify the presence or absence of main functional groups in the system, to demonstrate the relative arrangement of the hydroxide layers, and to set the extent of ordering of water in the sample) about the interlayer environment. In addition, we obtain exact information about the distortion that the intercalated molecules underwent by comparing the spectra of the original LDHs with those of the intercalated compounds [28].
The functional groups of cephradine (Fig. 2A) were first confirmed from characteristic peaks at 1766 and 1667 cm\(^{-1}\) recorded for carbonyl (=C=O) and amide I (–CO-NH\(_2\)) groups respectively. A sharp peak at 2345 cm\(^{-1}\) was also recognized for –C-N= which is present in the main structure of cephradine. The peaks between 2850 and 3000 cm\(^{-1}\) were accounted for C-H stretching of saturated and unsaturated structural positions.

Later we studied the synthesized Mg-Al-LDH compounds after drying at 105 °C. The ATR-IR spectra for Mg/Al-LDH (Fig. 2B) showed a broad and strong band in the range 3200-3600 cm\(^{-1}\) centered at 3448 cm\(^{-1}\) which was due to the O-H stretching vibration of the inorganic layers and interlayer water molecules. Another common wavenumber for LDH-like material is a band at 1650 cm\(^{-1}\) which is assigned to the bending vibration of interlayer water molecules [29]. For Mg/Al-LDH, bands in the lower wavenumber region corresponds to the lattice vibration mode such as the translation vibrations of Mg-OH at 750 cm\(^{-1}\) and deformation vibration of OH-Mg-Al-OH at 575 cm\(^{-1}\) were observed.

IR spectrum in Fig. 2C shows that cephradine was intercalated into the LDH interlayer space. A broad absorption band at around 3400 cm\(^{-1}\) for both nanohybrid arises from the stretching mode of OH groups in the brucite-like layer and/or physisorbed water [30]. The bands at 1732 cm\(^{-1}\) and 1643 cm\(^{-1}\) for cephradine and LDH are attributed to carboxylate functional group of the intercalated cephradine anion. A band at 1396 cm\(^{-1}\) for both nanohybrids can be attributed to C=C bond vibration of the aromatic group. The small peaks at 2343 and 2967 cm\(^{-1}\) attributed to –CH stretching of cephradine.

Figure 2. ATR-IR spectrum of cephradine (A) Mg-Al-LDH (B) and cephradine intercalated Mg-Al LDH.
Energy Dispersive X-Ray (EDX) elemental analysis

Energy Dispersive X-Ray was used for elemental analysis. The elements, carbon, hydrogen, nitrogen, and sulfur (CHNS) presents in a sample were determined as the mass percentage of the intercalated compound where unmodified LDH does not contain most of these elements namely nitrogen and sulfur. The results of the elemental analysis are furnished in the Table 1.

Table 1. Elements of Mg-Al LDH before and after modification with cephradine

| Type             | Elements (mass %) |
|------------------|-------------------|
|                  | Al    | Mg    | C  | O    | N    | S    |
| Mg-Al-LDH        | 36.16 | 8.63  | 4.73 | 50.48 | 0    | 0    |
| Cephradine - Mg-Al-LDH | 33.35 | 6.48  | 10.56 | 46.50 | 1.78 | 1.33 |

X-ray Diffraction analysis

XRD is a very useful tool to characterize crystal in terms of the crystalline structure, lattice parameters, morphology and size where the reflections of LDH crystal are indexed to a hexagonal lattice with rhombohedral 3R symmetry. The cell parameter $c$ (the thickness of one layer consisting of a brucite-like sheet and one interlayer) of LDH is usually estimated as $3d_{003}$ or $d_{003} + 2d_{006} + 3d_{009}$, and the cell parameter $a$ (the mean closest metal-metal distance within a layer) can be easily calculated from the 110 reflection ($a = 2d_{110}$), where diffraction planes (003), (006), (009) indicate the peaks of LDH from the lower angle to the high angle. We know that XRD measurement follows Bragg’s law: $n\lambda = 2d \sin \theta$, where $\lambda$ is the wavelength of the incident X-ray beam, $d$ is the spacing between each lattice, $\theta$ is the angle between the incident X-ray beam and the reflecting crystal plane, and $n$ is an integer representing the order of the reflection (in practice, taken to be 1) [31].

The XRD patterns of the unmodified and cephradine modified LDH are shown in Fig. 3A and B. As expected, the position of the first order basal reflection $<003>$ in the modified samples is shifted to a higher $d$-value indicating an expansion in the interlayer distance. Although modified sample did not show distinct reflection at $d = 0.76$ nm, their existence with a weak and broad reflection in the close vicinity, which may be either due to the crystallinity distortion of original LDH occurred by inserted cephradine molecules or due to a higher order reflection in $<00l>$ series in the modified LDH. However, the first statement seems that the XRD pattern of the modified sample show reflections corresponding to single $<00l>$ series and no mixed $<hkl>$ as compared to the unmodified Mg-Al-LDH. The disappearance of reflection corresponding to mixed $<hkl>$ series also indicates a loss of crystallinity of Mg-Al LDH after cephradine modification. This may be due to the loss of coherent conditions and/or the presence of only small crystallites for all other directions in the sense of scattering [31].
Table 2. Assignment of various XRD reflections obtained for LDH and cephradine intercalated Mg-Al-LDH.

| Materials        | Reflections in <00l> series | 2θ (deg) | d(nm) | 2θ (deg) | d(nm) | 2θ (deg) | d(nm) |
|------------------|-----------------------------|----------|-------|----------|-------|----------|-------|
| LDH              |                             | 11.60    | 0.76  | 23.40    | 0.34  | 34.50    | 0.26  |
| Cephradine-LDH   |                             | 2.67     | 3.28  | 5.40     | 1.57  | 7.96     | 1.05  |

Scanning electron morphological analysis

Scanning electron microscopy (SEM) was used to elucidate the structural morphology and crystal growth of LDH, which provided useful information about the particle size and bulk strata of the LDH-composite materials. The particles size distribution of LDH depends mostly on the synthesis conditions and varies from few hundred nm to few micrometer in lateral dimensions [32]. The synthesized Mg-Al–LDH has usually plate-like particle morphology. In Fig. 4, the SEM micrograph of the synthesized LDH shows the particle geometry where the primary plate-like particles are characterized by distinct hexagonal shapes grain with sharp edges (Fig. 4A and C). The highly anisometric nature of these primary particles is also apparent which reflects with varying degree of structural shapes in the images. The lateral dimension of these plate-like particles varies within few micrometer whereas the thickness hardly exceeds few 100 nm. After cephradine intercalation (Fig. 4B), a laminar and ordered structure was produced, therefore, the coarse particles are not observed which is justified by XRD as the amorphous structures are obtained due to lose of crystallinity of Mg-Al-LDH (Fig. 4D).
Conclusion

In this study, cephradine intercalated LDH was prepared by co-precipitation method. The intercalation phenomenon shows that cephradine drug was modified as cephradine-LDH intercalated composite. The presence of functional groups of cephradine in Mg-Al LDH compounds was confirmed using ATR-IR. The position of the first order basal reflection $<003>$ in the cephradine modified LDH was shifted to a higher d-value indicating an expansion in the interlayer distance. Therefore, we can predict better bio-availability of cephradine and drugs like cephradine in presence of LDH as an intercalated composite for sustain release and more thermal stability. This study regarding drug intercalated LDH will help pharmaceutical sectors both theoretically and practically.
