Abstract: General Successive Convex Relaxation Methods (SRCMs) can be used to compute the convex hull of any compact set, in an Euclidean space, described by a system of quadratic inequalities and a compact convex set. Linear Complementarity Problems (LCPs) make an interesting and rich class of structured nonconvex optimization problems. In this paper, we study a few of the specialized lift-and-project methods and some of the possible ways of applying the general SCRMs to LCPs and related problems.

Keywords: Nonconvex Quadratic Optimization, Linear Complementarity Problem, Semidefinite Programming, Global Optimization, SDP Relaxation, Convex Relaxation, Lift-and-Project Procedures.

1 Introduction, SCRM and Lovász-Schrijver procedures

Since 1960’s, complementarity problems attracted a very significant attention in the theory as well as applications of operations research. See, for instance, the book on LCP [4]. In this paper, we consider various complementarity problems in the context of Successive Convex Relaxation Methods (SCRMs) proposed by the authors [5, 6]. Since these methods can be used to compute the convex hull of any compact subset of an Euclidean space described by a system of quadratic inequalities and a compact convex set, they can be used to attack many complementarity problems from several angles.

In the special case of 0-1 optimization problems over convex sets, or more specially polytopes, there are many Successive Convex Relaxation Methods (SCRMs) based on lift-and-project techniques. We also discuss some of the relationships of general SCRM and these more specialized algorithms in solving LCPs.

Let $F$ be a compact set in the $n$-dimensional Euclidean space $\mathbb{R}^n$. SCRM take as input, a compact convex subset $C_0$ of $\mathbb{R}^n$ and a set $P_F$ of quadratic functions which induce a description of $F$ such that

$$F = \{ x \in C_0 : qf(x; \gamma, q, Q) \leq 0, \ qf(\cdot ; \gamma, q, Q) \in P_F \}.$$  

Here we denote by $qf(\cdot ; \gamma, q, Q)$, the quadratic function $(\gamma + 2q^Tx + x^TQx)$. Note that the variable $x$ is irrelevant outside a context and it will always be clear what the variable vector is, from the context.

Let $\ell$ be an integer such that $1 < 2\ell \leq m$, $d \in \mathbb{R}^m$, and let $A$ be a compact convex subset of $\mathbb{R}^m$. Consider the convex optimization problem with complementarity conditions:

$$\begin{align*}
\text{maximize} & \quad d^T u \\
\text{subject to} & \quad u \in A, \ 0 \leq u_i, \ 0 \leq u_{i+\ell}, \ u_i u_{i+\ell} = 0, \ \forall i \in \{1, 2, \ldots, \ell\}. 
\end{align*}$$

First of all, it is clear that LCP, with a known upper bound on a solution of it, is a special case of (1) (we can take $m = 2\ell$ and $A$ as an affine subspace intersected with a large enough ball). Secondly, it is very elementary to formulate this problem as a mixed 0-1 optimization problem with convex constraints:

$$\begin{align*}
\text{maximize} & \quad c^Tv \\
\text{subject to} & \quad v \in C_0, \ v_i \in \{0, 1\}, \ \forall i \in \{m + 1, m + 2, \ldots, n\}, 
\end{align*}$$

where

$$C_0 \equiv \begin{pmatrix}
\mathbf{u} \\
v_{m+1} \\
\vdots \\
v_n
\end{pmatrix} \in \mathbb{R}^{m+\ell} : \begin{cases} 
\mathbf{u} \in A, \\
0 \leq u_i \leq rv_{m+i}, \\
0 \leq u_{i+\ell} \leq r(1-v_{m+i}), \\
\forall i \in \{1, 2, \ldots, \ell\}
\end{cases}, \ c \equiv \begin{pmatrix} d \\ 0 \end{pmatrix} \in \mathbb{R}^{m+\ell},$$

$$n \equiv m + \ell, \ r \geq \max_i \{ \max \{ u_i \ : \ u \in A \} \}.$$
In general, we allow $C_0$ to be an arbitrary compact convex set in $R^n$. There are various successive convex relaxation methods that can be applied to such a problem.

We can represent the feasible region $F \subset R^n$ of (2) as

$$F = \{v \in C_0 : p(v) \leq 0, \forall p(\cdot) \in P_F\},$$

where $P_F$ denotes a set consisting of quadratic functions

$$(v_i^2 - v_i), (-v_i^2 + v_i), \ i \in \{m+1, m+2, \ldots, n\}$$
on $R^n$.

In connection with the SCRMs and also the Lovász-Schrijver procedures (see [8]), it seems convenient to introduce the following notation: For every compact convex relaxation $C \subseteq C_0$ of $F$ and every subset $D$ of $\overline{D} \equiv \{d \in R^n : \|d\| = 1\}$,

$$\mathcal{P}^2(C, D) \equiv \{-(d^T v - \alpha(C_0, d))(\bar{d}^T \bar{v} - \alpha(C, \bar{d})) : d \in D, \bar{d} \in \overline{D}\},$$

(a Semi-Infinite LP relaxation of $F$),

$$\tilde{\mathcal{N}}(C, D) \equiv \begin{cases} v \in C_0 : \gamma + 2q^T v + Q \cdot V \leq 0, \\ \forall qf(\cdot; \gamma, q, Q) \in P_F \cup \mathcal{P}^2(C, D) \end{cases}$$

(\text{an SDP relaxation of } F),

where $\alpha(C, d) \equiv \max\{d^T v : v \in C\}$ for every $d \in \overline{D}$. Let $S^n$ and $S^{1+n}_+$ denote the set of $n \times n$ symmetric matrices and the set of $(1+n) \times (1+n)$ symmetric positive semidefinite matrices, respectively. The corresponding variants of Successive Semi-Infinite LP Relaxation Method (SSILPRM) and Successive SDP Relaxation Method (SSDPRM) can be written as follows.

**Algorithm 1.1. (SSILPRM)**

1. **Step 0:** Choose a $D_0 \subseteq \overline{D}$. Let $k = 0$.
2. **Step 1:** If $C_k = (\text{the convex hull of } F)$, then stop.
3. **Step 2:** Let $C_{k+1} = \tilde{\mathcal{N}}(C_k, D_0)$.
4. **Step 3:** Let $k = k + 1$, and go to Step 1.

**Algorithm 1.2. (SSDPRM)**

1. **Steps 0, 1 and 3:** The same as the Steps 0, 1 and 3 of Algorithm [1].
Step 2: Let $C_{k+1} = \tilde{N}_+(C_k, D_0)$.

To connect these algorithms to the Lovász-Schrijver procedures, we need to introduce some additional notation. For every pair of closed convex cones $K$ and $T$ in $R^{1+n}$, define

$$M(K, T) \equiv \{ Y = \begin{pmatrix} \lambda & \lambda v^T \\ \lambda v & \lambda V \end{pmatrix} : \lambda \geq 0, \ v \in C_0, \ V \in S^n, \ v_i = V_{ii}, \ i \in \{ m+1, m+2, \ldots, n \}, \ v^T Y w \geq 0, \ \forall v \in T^*, \ \forall w \in K^* \}.$$ 

$$M_+(K, T) \equiv \{ Y = \begin{pmatrix} \lambda & \lambda v^T \\ \lambda v & \lambda V \end{pmatrix} : \lambda \geq 0, \ v \in C_0, \ V \in S^n, \ Y \in S_+^{1+n}, \ v_i = V_{ii}, \ i \in \{ m+1, m+2, \ldots, n \}, \ v^T Y w \geq 0, \ \forall v \in T^*, \ \forall w \in K^* \}.$$ 

Let $T_0$ and $K_0$ be closed convex cones given by

$$T_0^* = \text{c.cone} \left\{ \left( \begin{array}{c} \alpha(C_0, d) \\ -d \end{array} \right) \in R^{1+n} : d \in D_0 \right\},$$

$$K_0 = \left\{ \begin{pmatrix} \lambda \\ \lambda v \end{pmatrix} \in R^{1+n} : v \in C_0, \ \lambda \geq 0 \right\}.$$ 

(Note that $T_0$ itself is defined as the dual of $T_0^*$.) If $C \subseteq C_0$ is a compact convex relaxation of $F$ and

$$K = \left\{ \begin{pmatrix} \lambda \\ \lambda v \end{pmatrix} \in R^{1+n} : v \in C, \ \lambda \geq 0 \right\},$$

then

$$\tilde{N}(C, D_0) = \left\{ v \in R^n : \begin{pmatrix} 1 & v^T \\ v & V \end{pmatrix} \in M(K, T_0) \right\},$$

$$\tilde{N}_+(C, D_0) = \left\{ v \in R^n : \begin{pmatrix} 1 & v^T \\ v & V \end{pmatrix} \in M_+(K, T_0) \right\}.$$ 

Algorithms 1.1 and 1.2 specialized to (2) with $P_F = \{ v_i^2 - v_i, -v_i^2 + v_i, \ i \in \{ m+1, m+ 2, \ldots, n \} \}$ can be stated in the following forms, which are essentially the Lovász-Schrijver procedures.

**Algorithm 1.1H** (Homogeneous form of Algorithm 1.1)

Step 0: Choose a $D_0 \subseteq D$. Define $T_0$ and $K_0$ as above. Let $k = 0$.

Step 1: If $K_k = \text{c.cone} \left\{ \begin{pmatrix} 1 \\ v \end{pmatrix} : v \in F \right\}$ then stop.

Step 2: Let $K_{k+1} = \{ Ye_0 : Y \in M(K, T_0) \}$.

Step 3: Let $k = k + 1$, and go to Step 1.

**Algorithm 1.2H** (Homogeneous form of Algorithm 1.2)
Steps 0, 1 and 3: The same as Steps 0, 1 and 3 of Algorithm 1.2H, respectively.

Step 2: Let \( K_{k+1} = \{ Ye_0 : Y \in M_+(K_k, T_0) \} \).

In this paper \( e_j \) denotes the \( j \)th unit vector and \( e \) denotes the vector of all ones (the dimensions of the vectors will be clear from the context).

## 2 SCRMs applied to LCP with an á priori bound

Let \( M \in R^{\ell \times \ell} \), \( q \in R^\ell \) be given. Consider the LCP in the following form.

\[
\text{(LCP) Find } x, s \text{ such that } \begin{align*}
Mx + q &= s, \\
x &\geq 0, \ s \geq 0, \\
x_is_i &= 0, \ \forall \ i \in \{1,2,\ldots,\ell\}.
\end{align*}
\]

Suppose we are given \( B(\xi, r) \equiv \{ u \in R^{2\ell} : \|u - \xi\| \leq r \} \), an Euclidean ball containing a solution of the LCP. (In the case of rational data \((M, q)\), we can take \( B \) centered at the origin with the radius bounded above by a polynomial function of the “bit size” of the data \((M, q)\).) For the rest of this section, we assume that the Euclidean ball with center \( \xi \equiv 0 \) and the radius \( r \) (\( r \) is assumed given) contains some solution of the LCP.

Under the boundedness assumption above, it is particularly easy to model any LCP as a 0-1 mixed integer programming problem, since the only nonlinear constraints of LCP can be expressed as

\[
x_i = 0, \ \text{ or } s_i = 0, \ \forall \ i \in \{1,2,\ldots,\ell\}.
\]

Balas’ method \[1\] can be directly applied to such formulations. We can also apply some variants of the Lovász-Schrijver procedures \[8\] to the mixed integer programming feasibility problem:

\[
\text{Find } x, s \text{ and } z \text{ such that } \begin{align*}
Mx + q &= s, \\
0 &\leq x \leq rz, \ 0 \leq s \leq r(e - z), \\
z &\in \{0,1\}^\ell.
\end{align*}
\]

Note that we can eliminate the variable vector \( s \) from the formulation and apply the SSILPR and SSDPR Methods to the following formulation:

\[
\begin{align*}
0 &\leq Mx + q \leq r(e - z), \\
0 &\leq z \leq e, \ 0 \leq x \leq rz, \\
z_i^2 - z_i &\leq 0, \ -z_i^2 + z_i \leq 0, \ i \in \{1,2,\ldots,\ell\}.
\end{align*}
\]

To apply the SCRMs, we can take

\[
C_0 \equiv \left\{ v = \begin{pmatrix} x \\ z \end{pmatrix} \in R^n : \begin{align*}
0 &\leq Mx + q \leq r(e - z), \\
0 &\leq z \leq e, \ 0 \leq x \leq rz
\end{align*} \right\},
\]

\[
m \equiv \ell, \ n \equiv 2\ell,
\]

\[
P_F \equiv \left\{ (v_i^2 - v_i), \ (-v_i^2 + v_i), \ i \in \{m+1,m+2,\ldots,n\} \right\}.
\]
Both algorithms, SSILPRM and SSDPRM presented in Section 1, terminate in at most \( \ell \) steps. This fact can be proved easily, using the results of Balas [1], Sherali and Adams [10], Lovász and Schrijver [8], or Kojima and Tunçel [5, 6]. For computational experience on similar algorithms for similar problems see [3], [12]. In the next section, we give the details of a proof of such a convergence result when the methods are applied to a formulation of Pardalos and Rosen [9].

3 SCRMs applied to Pardalos-Rosen formulation of LCP

We will illustrate the convergence proof on a formulation of (LCP) by Pardalos and Rosen [9]. They homogenize the vector \( q \) with a new continuous variable \( \alpha \), then they maximize \( \alpha \).

\[
\text{(MIP}_\alpha \text{)} \quad \begin{array}{rl}
\text{maximize} & \alpha \\
\text{subject to} & 0 \leq Mx + q\alpha \leq e - z, \\
& 0 \leq x \leq z, 0 \leq \alpha \leq 1, z \in \{0, 1\}^\ell.
\end{array}
\]

Note that \( \begin{pmatrix} \bar{\alpha} \\ \bar{x} \\ \bar{z} \end{pmatrix} \equiv 0 \) is feasible in (MIP\(_\alpha \)) and, it is easy to see that (MIP\(_\alpha \)) has an optimal solution with \( \alpha^* > 0 \) iff the (LCP) has a solution (or solutions) \[\lozenge\]. Moreover, if \( \begin{pmatrix} \alpha^*_i \\ x^*_i \\ z^*_i \end{pmatrix} \) is an optimal solution of (MIP\(_\alpha \)) with \( \alpha^*_i > 0 \) then \( \frac{x^*_i}{\alpha^*_i} \) solves the (LCP) \[\lozenge\]. One advantage of (MIP\(_\alpha \)) is that it does not require the introduction of large, data dependent constants (such as \( r \) in the previous section) or their a priori estimates. Now, we take

\[
C_0 \equiv \left\{ v = \begin{pmatrix} \alpha \\ x \\ z \end{pmatrix} \in \mathbb{R}^{1+2\ell} : \begin{array}{ll}
0 \leq Mx + q\alpha \leq e - z, \\
0 \leq x \leq z, 0 \leq \alpha \leq 1
\end{array} \right\},
\]

\[
m \equiv \ell + 1, \quad n \equiv 2\ell + 1,
\]

\[
P_F \equiv \{(v_i^2 - v_i), (-v_i^2 + v_i), i \in \{m + 1, m + 2, \ldots, n\}\}.
\]

We have an analog of a very elementary but also a key lemma (Lemma 1.3 of [8]) of Lovász and Schrijver (and their proof technique is adapted here). In what follows, we refer to the vectors in the space of \( \mathcal{K}_k \) by \( v \). At the same time, we refer to different subvectors of \( v \) by different names, such as \( x, \alpha \) etc., to keep the correspondence of elements of \( v \) and the original formulation of \( F \) clearer. The proof of Lemma 1.3 of [8] leads to the following analogous result in our case.

**Lemma 3.1.** Let \( D_0 \supseteq \{\pm e_{m+1}, \pm e_{m+2}, \ldots, \pm e_n\} \). Then the sequence of convex cones \( \{\mathcal{K}_k : k \geq 0\} \) given by Algorithm 1.1H satisfies

\[
\mathcal{K}_{k+1} \subseteq (\mathcal{K}_k \cap \{v : x_i = 0\}) + (\mathcal{K}_k \cap \{v : (Mx + q\alpha)_i = 0\}),
\]

for every \( i \in \{1, 2, \ldots, \ell\} \), and for every \( k \geq 0 \).
Theorem 3.2. SSDPR Method yields at least as tight relaxations as the SSILPR Method.

Proof: Let \( \mathbf{w} \equiv \begin{pmatrix} 1 \\ \alpha \\ \mathbf{x} \\ \mathbf{z} \end{pmatrix} \in \mathcal{K}_{k+1} \). Fix \( j \in \{1,2,\ldots,\ell\} \) arbitrarily. By the definition of \( D_0 \) and \( \mathcal{T}_0 \), the unit vector \( \mathbf{e}_0 \) is in \( \mathcal{T}_0 \). Hence, by the definition of \( \mathcal{M}(\mathcal{K}_k, \mathcal{T}_0) \), \( \mathcal{K}_{k+1} \subseteq \mathcal{K}_k \) for every \( k \geq 0 \). Therefore, \( \mathbf{w} \in \mathcal{K}_k \). If \( \bar{x}_j = 0 \) or \( (\mathbf{Mx} + q\alpha)_j = 0 \) then the statement of the lemma clearly holds. So, without loss of generality, we assume \( \bar{x}_j > 0 \) and \( (\mathbf{Mx} + q\alpha)_j > 0 \). Let \( \mathbf{Y} \in \mathcal{M}(\mathcal{K}_k, \mathcal{T}_0) \) such that \( \mathbf{w} = \mathbf{Ye}_0 \). By our choice of the cone \( \mathcal{T}_0 \), we conclude that \( \mathbf{Ye}_{n+j} \) and \( \mathbf{Y}(\mathbf{e}_0 - \mathbf{e}_{n+j}) \) are both in \( \mathcal{K}_k \). Note that

\[
\mathbf{w} = \hat{\mathbf{w}} + \bar{\mathbf{w}}
\]

where \( \hat{\mathbf{w}} \equiv \mathbf{Ye}_{n+j} \) and \( \bar{\mathbf{w}} \equiv \mathbf{Y}(\mathbf{e}_0 - \mathbf{e}_{n+j}) \). We will refer to the \( \mathbf{x} \) and \( \mathbf{z} \) parts of the vector \( \hat{\mathbf{w}} \) by \( \hat{\mathbf{x}}, \hat{\mathbf{z}} \) etc. (Similarly for \( \bar{\mathbf{w}} \).) First, since by the definition of \( \mathcal{M}(\mathcal{K}_k, \mathcal{T}_0) \), \( v_i = V_i \) for every \( i \in \{m+1, m+2, \ldots, n\} \), we have \( \bar{z}_j = 0 \) which implies \( \bar{x}_j = 0 \). Therefore, \( \hat{\mathbf{w}} \) lies in the cone \( (\mathcal{K}_0 \cap \{ \mathbf{v} : x_j = 0 \}) \). Second, since \( \bar{x}_j > 0 \), \( \bar{z}_j \) must be positive. Therefore, \( (1/\bar{z}_j)\bar{\mathbf{w}} \in \mathcal{K}_0 \). Since \( v_i = V_i \) for every \( i \in \{m+1, m+2, \ldots, n\} \), \( \bar{z}_j = \bar{z}_j \). So,

\[
\frac{1}{\bar{z}_j} \begin{pmatrix} \hat{\alpha} \\ \hat{\mathbf{x}} \\ \hat{\mathbf{z}} \end{pmatrix} \in \mathcal{K}_k,
\]

with its \( z_j \) entry equal to 1. Thus, \( (\mathbf{M}\hat{\mathbf{x}} + q\hat{\alpha})_j = 0 \). Hence, \( \hat{\mathbf{w}} \) is in the cone \( (\mathcal{K}_k \cap \{ \mathbf{v} : (\mathbf{M}\mathbf{x} + q\alpha)_j = 0 \}) \). Since the argument above is independent of the index \( j \) the proof is complete. \( \blacksquare \)

Note that the conclusion of the above lemma also applies to the SSDPR Method since SSDPR Method yields at least as tight relaxations as the SSILPR Method.

**Theorem 3.2.** Both algorithms, Algorithm 1.1H and 1.2H terminate in \( \ell \) iterations when applied to the formulation (MIP\(_\alpha\)) with our choice of \( \mathcal{P}_F \), \( C_0 \) and \( D_0 \) above.

Proof: First note that

\[
\text{c.hull}(F) \subseteq \left\{ \begin{pmatrix} \alpha \\ \mathbf{x} \\ \mathbf{z} \end{pmatrix} \in \mathbb{R}^n : \begin{pmatrix} 1 \\ \alpha \\ \mathbf{x} \\ \mathbf{z} \end{pmatrix} \in \mathcal{K}_k \right\}, \ \forall k \geq 0.
\]

Next, let \( i, j \in \{1,2,\ldots,\ell\} \), \( i \neq j \). Since \( \mathbf{x} \geq 0 \) and \( \mathbf{Mx} + q\alpha \geq 0 \), for all \( \mathbf{v} \in \mathcal{K}_k \), for every \( k \geq 0 \),

\[
[(\mathcal{K}_k \cap \{ \mathbf{v} : x_i = 0 \}) + (\mathcal{K}_k \cap \{ \mathbf{v} : (\mathbf{M}\mathbf{x} + q\alpha)_i = 0 \})] \cap \{ \mathbf{v} : x_j = 0 \}
= (\mathcal{K}_k \cap \{ \mathbf{v} : x_i = 0, x_j = 0 \}) + (\mathcal{K}_k \cap \{ \mathbf{v} : x_j = 0, (\mathbf{M}\mathbf{x} + q\alpha)_i = 0 \})
\]

Similarly, for the intersection with \( \{ \mathbf{v} : (\mathbf{M}\mathbf{x} + q\alpha)_j = 0 \} \). Now, we apply Lemma [3.1] repeatedly to conclude that \( \mathcal{K}_k \) is the homogenization of the convex hull of all solutions of the LCP that lie in the original relaxation \( C_0 \). \( \blacksquare \)
4 SCRM applied to the smaller formulation of LCP with explicit treatment of disjunctive constraints

Now, we consider a formulation with fewer variables and constraints.

\[(\text{LCP}_\alpha) \text{ maximize } \alpha \text{ subject to } \begin{align*}
Mx + q\alpha & \geq 0, x \geq 0, \alpha \geq 0, \\
\alpha & \leq 1,
\end{align*} \]

\[x_i(Mx + q\alpha)_i = 0, i \in \{1, 2, \ldots, \ell\}.\]

It is easy to see that \((\bar{x}, \bar{\alpha}) \equiv 0\) is feasible in \((\text{LCP}_\alpha)\), and it is also easy to observe that \((\text{LCP}_\alpha)\) has an optimal solution with \(\alpha^* > 0\) iff the \((\text{LCP})\) has a solution(or solutions). Moreover, if \((x^*, \alpha^*)\) is an optimal solution of \((\text{LCP}_\alpha)\) with \(\alpha^* > 0\) then \(\frac{x^*}{\alpha^*}\) solves the \((\text{LCP})\).

We explicitly include the variable vector \(s\) in our discussion in this section, for the sake of presentation. Let

\[C_0 \equiv \left\{ v = \begin{pmatrix} x \\ s \\ \alpha \end{pmatrix} \in \mathbb{R}^{2\ell+1} : \begin{align*}
s = Mx + q\alpha & \geq 0, x \geq 0, \alpha \geq 0, \\
e^T(M + I)x + (e^Tq + 1)\alpha & \leq 1,
\end{align*} \right\}.\]

In this section, we will describe another Successive Convex Relaxation Method based on the ideas of Balas [1], Lovász and Schrijver [8]. This method will use only Linear Programming (LP) relaxations. We describe the method in the original space of \(F\) and \(C_0\). Let \(\mathcal{F}(C_0)\) denote the set of facet defining inequalities for \(C_0\). \(\mathcal{F}(C_0)\) is the input of the algorithm which we introduce now.

Algorithm 4.1. Step 0. \(k \equiv 0\).
Step 1. \(\mathcal{F}(C_{k+1}) \equiv \mathcal{F}(C_k)\).
Step 2. For every inequality

\[-\sum_{i=1}^{\ell} (u_i x_i + u_{\ell+i}s_i) - u_{2\ell+1}\alpha \leq u_0\]

in \(\mathcal{F}(C_k)\) and every \(j \in \{1, 2, \ldots, \ell\}\) solve the LP problems

\[(P_j) \text{ minimize } u^T\xi(j) \text{ subject to } \xi(j) = 1, \xi_{\ell+j} = 0, \xi^{(j)} \in \mathcal{K}_k,\]

and

\[(P_{\ell+j}) \text{ minimize } u^T\xi^{(\ell+j)} \text{ subject to } \xi_1 = 0, \xi_{\ell+1} = 1, \xi^{(\ell+j)} \in \mathcal{K}_k.\]
If \((P_j)\) is infeasible then add the equation \(x_j = 0\) (or the inequality \(x_j \leq 0\), since the inequality \(x_j \geq 0\) is already included) to \(F(C_{k+1})\). If \((P_{\ell+j})\) is infeasible then add the equation \(s_j = 0\) to \(F(C_{k+1})\). Otherwise, let \((\xi^{(j)})^*\) and \((\xi^{(\ell+j)})^*\) denote the optimal solutions of \((P_j)\) and \((P_{\ell+j})\) respectively. Define \(y_j \equiv u_j - u^T(\xi^{(j)})^*\), \(y_{\ell+j} \equiv u_{\ell+j} - u^T(\xi^{(\ell+j)})^*\). Add the inequality
\[
- \sum_{i \neq j} (u_ix_i + u_{\ell+i}s_i) - y_jx_j - y_{\ell+j}s_j - u_{2\ell+1}\alpha \leq u_0
\]
to \(F(C_{k+1})\).

**Step 3.** Let \(k = k + 1\), and go to Step 1.

Note that in iteration \(k\), the algorithm solves \((2\ell|F(C_k)|)\) LP problems.

**Theorem 4.2.** Let \(C_k, k \in \{1, 2, \ldots\}\) be the sequence of convex relaxations generated by Algorithm \([\text{I}4]\). Then \(C_\ell = c.hull(F)\).

**Proof:** We think of \(K_k\) for all \(k \geq 0\), as a subset of \(R^{1+(2\ell+1)}\), with the 0th component being the homogenizing variable, the next \(\ell\) components representing \(x\), the next \(\ell\) components representing \(s\) and the last component representing \(\alpha\). Note that
\[
K_1 \subseteq (K_0 \cap \{v : x_j = 0\}) + (K_0 \cap \{v : s_j = 0\})
\]
iff
\[
K_1^* \supseteq (K_0^* + \{-e_j\}) \cap (K_0^* + \{-e_{\ell+j}\}) \quad (3)
\]
(We used the fact that \(K_0 \subseteq R^{1+(2\ell+1)}\).) Therefore, if we ensure the latter inclusion, then Theorem \([3.2]\) applies and we can conclude the convergence of the method in \(\ell\) iterations. Recall that every vector \(u \in K_0^*\) represents a valid inequality
\[
- \sum_{i=1}^\ell (u_ix_i + u_{\ell+i}s_i) - u_{2\ell+1}\alpha \leq u_0
\]
for \(C_0\). To ensure the inclusion \([3]\), it suffices to prove:

“For every \(u, w \in K_0^*\) such that \(u_i = w_i, \forall i \notin \{j, \ell + j\}\); \(u_j \geq w_j, u_{\ell+j} \leq w_{\ell+j}\),
we have \(y \in K_1^*\), where \(y_i \equiv u_i, \forall i \neq j; y_j \equiv w_j\).”

This is equivalent to proving the fact that if the two inequalities
\[
- \sum_{i=1}^\ell (u_ix_i + u_{\ell+i}s_i) - u_{2\ell+1}\alpha \leq u_0, \quad \text{and}
- \sum_{i \neq j} (u_ix_i + u_{\ell+i}s_i) - w_jx_j - w_{\ell+j}s_j - u_{2\ell+1}\alpha \leq u_0
\]
are valid for \(C_0\), then
\[
- \sum_{i \neq j} (u_ix_i + u_{\ell+i}s_i) - w_jx_j - u_{\ell+j}s_j - u_{2\ell+1}\alpha \leq u_0
\]
is valid for \( C_1 \). To compute all such inequalities defining \( C_1 \), we solve for every valid inequality

\[
- \sum_{i=1}^{\ell} (u_i x_i + u_{\ell+i} s_i) - u_{2\ell+1} \alpha \leq u_0
\]

for \( C_0 \) and every \( j \in \{1, 2, \ldots, \ell\} \), the linear programming problems

\[
\text{maximize } \beta \\
\text{subject to } \beta e_j + \delta e_{\ell+j} \preceq_{K^*_0} u,
\]

and

\[
\text{maximize } \gamma \\
\text{subject to } \kappa e_j + \gamma e_{\ell+j} \preceq_{K^*_0} u.
\]

Here, \( \preceq_{K^*_0} \) denotes the partial order induced by the convex cone \( K^*_0 \) (that is, \( u^1 \preceq_{K^*_0} u^2 \) iff \((u^2 - u^1) \in K^*_0\)). Note that both problems are always feasible. Therefore, each of them either has an optimal solution or is unbounded. If both LPs have optimal solutions, say \( \beta^* \) and \( \gamma^* \) then we set \( w_j \equiv u_j - \beta^* \) and \( u_{\ell+j} \equiv u_{\ell+j} - \gamma^* \). Since the above two problems are LPs, we can equivalently solve their duals. Namely, we solve the LPs:

\[
(P_j) \quad \text{minimize } u^T \xi^{(j)} \\
\text{subject to } \xi_j^{(j)} = 1, \xi_{\ell+j}^{(j)} = 0, \xi^{(j)} \in K_0,
\]

and

\[
(P_{\ell+j}) \quad \text{minimize } u^T \xi^{(\ell+j)} \\
\text{subject to } \xi_j^{(\ell+j)} = 0, \xi_{\ell+j}^{(\ell+j)} = 1, \xi^{(\ell+j)} \in K_0.
\]

These latter two linear programming problems are precisely the ones used by Algorithm 4.1. Notice that since their duals are either unbounded or have optimal solutions, these LP problems either have optimal solutions or are infeasible. When \( (P_j) \) is infeasible, the equality \( x_j = 0 \) is valid for \( F \) and the algorithm adds this equality to the describing inequalities of \( C_k \). Similarly, when \( (P_{\ell+j}) \) is infeasible, \( s_j = 0 \) is valid for \( F \) and the algorithm behaves correctly in this instance. (In either instance, the inclusion (3) is obviously satisfied for \( j \).) However, the proof is not yet complete; because, the arguments so far ensure the inclusion (3) when the algorithm is ran for every valid inequality of \( C_0 \).

So, next we prove that what the algorithm does (using only the facets of \( C_0 \)) suffices. To see this, we need to prove that to derive the facets of \( K_1 \), it suffices to start with a facet \( u \) of \( K_0 \) in the above procedure. Suppose \( u, w \in K_0^* \) satisfy the above conditions but \( u \) is not facet inducing for \( K_0^* \). (We will prove that the valid inequality derived from \( u \) and \( w \) is implied by some other inequalities derived from some facets \( u^1, u^2, \ldots, u^\ell \) of \( K_0 \).) Since \( u \) is not facet inducing for \( K_0 \), \( u \) is not an extreme ray of \( K_0^* \). Hence, there exist extreme rays \( u^1, u^2, \ldots, u^\ell \) of \( K_0^* \) such that for some \( \lambda_r > 0, r \in \{1, 2, \ldots, \ell\} \), \( \sum_{r=1}^{\ell} \lambda_r = 1 \) the following conditions are satisfied:

\[
u = \sum_{r=1}^{\ell} \lambda_r u^r, \quad u_0^r = u_0, \quad \forall r \in \{1, 2, \ldots, \ell\}.
\]
Note that $\mathbf{u}^r$ is facet inducing for each $r$. Let $\xi^r$ be the optimal solution of ($P_j$) above for the objective function vector $\mathbf{u}^r$. Let $\xi^\ast$ be an optimal solution of ($P_j$) when the objective function vector is $\mathbf{u}$. We claim that there exists $\tilde{\xi} \in K_0$ such that

$$(\mathbf{u}^r)^T \xi^r = (\mathbf{u}^r)^T \xi^\ast, \quad \forall r \in \{1, 2, \ldots, \ell\}, \quad \tilde{\xi}_j = 1, \quad \tilde{\xi}_{\ell+j} = 0, \quad \tilde{\xi} \in K_0.$$ 

(This claim follows from Farkas’ Lemma, using the facts that $\mathbf{u}^r \in K_0^\ast, \forall r$ and $\xi^r \in K_0, \forall r$.) Thus, we have

$$\sum_{r=1}^\ell \lambda_r (\mathbf{u}^r)^T \xi^r = \mathbf{u}^T \tilde{\xi} \geq \mathbf{u}^T \xi^\ast.$$ 

Therefore, the inequality obtained from $\mathbf{u}$ is equivalent to or dominated by a nonnegative combination of the inequalities obtained from $\mathbf{u}^r$ which induce facets of $K_0$. The proof is complete.

We illustrated a derivation and convergence proof for a successive relaxation method (closely related to Balas’ approach and analogous to a suggestion of Lovász and Schrijver [8]) based on Lemma 3.1 and Theorem 3.2. Algorithm 1.1 is an analog of a method based on relaxations $N^b(K)$ from [8] (which is concerned with the case of 0-1 integer programming). For the relationship of the methods of [1] and [8], see Balas, Ceria and Cornuejols [2]. (Balas’ method [1], in essence, corresponds to defining

$$K_{k+1} \equiv (K_k \cap \{v : x_{k+1} = 0\}) + (K_0 \cap \{v : (Mx + qa)_{k+1} = 0\}).$$

Let $C_k^{(4)}$, $k \geq 0$ denote the projection of $C_k$ generated by Algorithm 1.1 onto the coordinates $\left(\begin{array}{c} x \\ \alpha \end{array}\right)$. Let $C_k^{(3)}$, $k \geq 0$ denote the projection of $C_k$, generated by Algorithm 1.1, as used in Section 3, onto the coordinates $\left(\begin{array}{c} x \\ \alpha \end{array}\right)$. Let $K_k^{(4)}$ denote the convex cone associated with $C_k^{(4)}$. From the proof of Theorem 4.2, it is easy to see that

$$K_{k+1}^{(4)} = \bigcap_{i=1}^\ell \left[(K_k^{(4)} \cap \{v : x_i = 0\}) + (K_k^{(4)} \cap \{v : s_i = 0\})\right].$$

Therefore, the proofs of Theorems 3.2 and 4.2 imply that

if $C_0^{(4)} \supseteq C_0^{(3)}$ then $C_k^{(4)} \supseteq C_k^{(3)}$ for all $k \geq 0$.

Thus, the SSILPR Method (Algorithm 1.1) as applied in Section 3 to (MIP$_\alpha$) converges at least as fast as Algorithm 4.1 applied to (LCP$_\alpha$).

5 SCRM applied to the smaller formulation of LCP with an implicit treatment of the disjunctive constraints

We have already seen various ways of applying SCRM to LCP problems. Since the methods proposed in [3, 4] only require a formulation of the feasible solutions by quadratic inequali-
ties, we are also interested in applying the methods of [5, 6] to the following formulation:

\[
C_0 \equiv \left\{ \left( \begin{array}{c} \alpha \\ x \end{array} \right) \in \mathbb{R}^{\ell+1} : \begin{array}{c} Mx + q\alpha \geq 0, \\ x \geq 0, \alpha \geq 0, \\ e^T(M + I)x + (e^Tq + 1)\alpha \leq 1 \end{array} \right\},
\]

and

\[
P_F \equiv \{ x_i(Mx + q\alpha) i \leq 0, \ i \in \{1, 2, \ldots, \ell\} \}.
\]

The general theory of Kojima-Tunçel [5] implies that their SSDPR and SSILPR Methods converge. It would be interesting to characterize the conditions under which the Algorithms 3.1 and 3.2 of [6] converge in at most \(\ell\) iterations for the above description of \(P_F\) and \(C_0\).

Also see [7], where the authors derived some necessary and some sufficient conditions for the finite convergence of SCRMs.

6 A general linear complementarity problem

Let \(A : \mathbb{R}^\ell \to \mathbb{R}^\ell\), a linear transformation, \(q \in \mathbb{R}^\ell\) and \(K \subset \mathbb{R}^\ell\) a pointed, closed convex cone with nonempty interior, be given. Consider the Complementarity Problem (CP):

(CP) Find \(x, s\) such that

\[
A(x) + q = s,
\]

\[
x \in K, \ s \in K^*, \ \langle x, s \rangle = 0,
\]

where \(K^*\) is the dual of \(K\):

\[
K^* \equiv \{ s \in \mathbb{R}^\ell : \langle x, s \rangle \geq 0, \ \forall x \in K\}.
\]

Since \(K\) is a pointed, closed convex cone with nonempty interior, so is \(K^*\). Such problems were studied recently, in the context of interior-point methods [11]. We pick \(\eta \in \text{int}(K)\), \(\bar{\eta} \in \text{int}(K^*)\) and we can solve instead the optimization problem

(CP\(\alpha\)) maximize \(\alpha\)

subject to \(x \in K, \ [A(x) + q\alpha] \in K^*\), \(\alpha \geq 0, \langle \eta, x \rangle + \langle \eta, A(x) + q\alpha \rangle + \alpha \leq 1, \langle x, A(x) + \alpha q \rangle = 0\).

We choose

\[
C_0 \equiv \left\{ \left( \begin{array}{c} \alpha \\ x \end{array} \right) \in \mathbb{R}^{\ell+1} : \begin{array}{c} x \in K, \ [A(x) + q\alpha] \in K^*, \ \alpha \geq 0, \\ \langle \bar{\eta}, x \rangle + \langle \eta, A(x) + q\alpha \rangle + \alpha \leq 1 \end{array} \right\}.
\]

Note that \(C_0\) is always a compact convex set (see the next theorem). We also pick

\[
P_F \equiv \{ \langle x, A(x) + \alpha q \rangle, -\langle x, A(x) + \alpha q \rangle \}.
\]

Theorem 6.1. (i) \(C_0\) is a compact convex set.
(ii) \((CP_\alpha)\) has an optimal solution with \(\alpha^* > 0\) iff \((CP)\) has a solution (or solutions).

(iii) If \(\left(\frac{\alpha^*}{x^*}\right)\) is an optimal solution of \((CP_\alpha)\) with \(\alpha^* > 0\) then the pair of vectors

\[
\left(\frac{x^*}{\alpha^*}, \frac{1}{\alpha^*}A(x^*) + q\right)
\]

solves \((CP)\).

Proof:

(i) We only need to show that \(C_0\) is bounded; because, \(C_0\) is a closed and convex subset of \(R^{\ell+1}\) by definition. Assume on the contrary that we can take an unbounded direction \(\left(\frac{\Delta\alpha}{\Delta x}\right) \neq 0\) in \(C_0\);

\[
\left(\frac{\Delta\alpha}{\Delta x}\right) \neq 0, \ \Delta x \in K, \Delta\alpha \geq 0, \ [A(\Delta x) + q\Delta\alpha] \in K^*, \langle \bar{\eta}, \Delta x \rangle + \langle \eta, A(\Delta x) + q\Delta\alpha \rangle + \Delta\alpha \leq 0.
\]

Since each term in the left hand side of the last inequality is nonnegative, we have

\[
\langle \bar{\eta}, \Delta x \rangle = 0 \text{ and } \Delta\alpha = 0.
\]

Since \(\bar{\eta} \in \text{int}(K^*)\) and \(\Delta x \in K\), the first identity above implies that \(\Delta x = 0\). Thus, we have a contradiction to \(\left(\frac{\Delta\alpha}{\Delta x}\right) \neq 0\).

(ii) Suppose \((CP_\alpha)\) has an optimal solution \(\left(\frac{\alpha^*}{x^*}\right)\) with \(\alpha^* > 0\). Then \(\bar{x} \equiv \frac{x^*}{\alpha^*} \in K\), \(\bar{s} \equiv \frac{1}{\alpha^*}A(x^*) + q \in K^*.\) We have

\[
\langle \bar{x}, \bar{s} \rangle = \langle \bar{x}, A(\bar{x}) + q \rangle = \frac{1}{(\alpha^*)^2} \langle x^*, A(x^*) + \alpha^*q \rangle = 0.
\]

Therefore, \((\bar{x}, \bar{s})\) solves \((CP)\). For the converse, let \((\bar{x}, \bar{s})\) be a solution of \((CP)\). Let

\[
\zeta \equiv \langle \bar{\eta}, \bar{x} \rangle + \langle \eta, \bar{s} \rangle \geq 0, \ \alpha^* = \frac{1}{\zeta + 1} \text{ and } x^* = \frac{\bar{x}}{\zeta + 1}.
\]

Then \(\left(\frac{\alpha^*}{x^*}\right)\) is a feasible solution of \((CP_\alpha)\). But the feasible region of \((CP_\alpha)\) is compact and nonempty, its objective function is linear, hence, \((CP_\alpha)\) has optimal solution (or solutions). Since we already showed a solution with positive objective value, the optimum value is positive.

(iii) This claim follows from the proof of (ii).

Theorem 6.1 shows that we can apply SCRM to \((CP_\alpha)\) with the above \(C_0\) and \(P_F\) and solve the original, general problem \((CP)\).
