Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Meta-trial of awake prone positioning with nasal high flow therapy: Invitation to join a pandemic collaborative research effort

Jie Li, Ivan Pavlov, John G. Laffey, Oriol Roca, Sara Mirza, Yonatan Perez, Bairbre McNicholas, David Cosgrave, David Vines, Elsa Tavernier, Stephan Ehrmann.

1. Introduction

The ongoing coronavirus disease pandemic (COVID-19) poses a great challenge to healthcare systems worldwide. Beyond challenges for direct patient care, optimal conduct of research under the specific conditions of the pandemic is a matter of concern and discussion. We present the meta-trial concept as a scientifically, clinically, ethically and socially sound method to carry out optimal clinical research in the setting of a pandemic. We take the example of such a meta-trial, set up to investigate prone positioning among awake patients undergoing nasal high flow therapy and invite journal readers to join this collaborative research effort.

2. COVID-19 constraints to clinical research

The pandemic has placed the research community under great pressure with the urgent need for results, given the lack of knowledge concerning optimal management of patients suffering this new disease. Public pressure is high due to the lack of specific effective therapy regarding this major threat to public health; the traditional pace of clinical research being considered as not adapted by most stakeholders. Worldwide funding agencies and regulatory bodies changed their procedures in order to speed up the research process. This effort has led to the launch of a high number of clinical trials within a short period of time to an unprecedented extent.

The submission of numerous such trials launched simultaneously across hospitals in various countries address similar research questions. E.g. the search terms of “COVID AND Prone” to retrieve studies evaluating patient prone positioning on clinicaltrials.gov yielded 6, 31 and 44 results on the 5th of April, 5th of May and 5th of June respectively. This poses a major risk of redundant work, poor research resource allocation and incompletion of some trials – this happened all too often during previous epidemics [1-3]. Researchers may waste time writing protocols from scratch while others already obtained funding or regulatory approvals. Although data generated by these numerous trials may ultimately be meta-analyzed, the time required for these numerous individual trials to publish and then compile data may be incompatible with the pressure of the epidemic. Several stakeholders called for a coordinated research effort, which should ideally take place at the international level [1].

However, setting up an international trial requires tremendous resources and time to finalize a unique protocol translated in various languages, coordinate all regulatory and ethical approvals, and conduct trials and data quality assessment in each country [4,5]. Such efforts have been conducted successfully for observational studies with the support of international research networks and scientific societies [6]. However, the hurdles to set up a large scale international interventional randomized controlled trial are incompatible with the resources of an academic sponsor and are thus often restricted to pharmaceutical companies. When evaluating non-pharmacological interventions such as prone positioning, which has been proven to reduce mortality in mechanically ventilated patients with ARDS [7], the lack of foreseeable return on investment precludes such funding.

3. Pros/cons of national independent trials vs international trials

Numerous such trials launched simultaneously across hospitals in various countries address similar research questions. E.g. the search terms of “COVID AND Prone” to retrieve studies evaluating patient prone positioning on clinicaltrials.gov yielded 6, 31 and 44 results on the 5th of April, 5th of May and 5th of June respectively. This poses a major risk of redundant work, poor research resource allocation and incompletion of some trials – this happened all too often during previous epidemics [1-3]. Researchers may waste time writing protocols from scratch while others already obtained funding or regulatory approvals. Although data generated by these numerous trials may ultimately be meta-analyzed, the time required for these numerous individual trials to publish and then compile data may be incompatible with the pressure of the epidemic. Several stakeholders called for a coordinated research effort, which should ideally take place at the international level [1].

However, setting up an international trial requires tremendous resources and time to finalize a unique protocol translated in various languages, coordinate all regulatory and ethical approvals, and conduct trials and data quality assessment in each country [4,5]. Such efforts have been conducted successfully for observational studies with the support of international research networks and scientific societies [6]. However, the hurdles to set up a large scale international interventional randomized controlled trial are incompatible with the resources of an academic sponsor and are thus often restricted to pharmaceutical companies. When evaluating non-pharmacological interventions such as prone positioning, which has been proven to reduce mortality in mechanically ventilated patients with ARDS [7], the lack of foreseeable return on investment precludes such funding.
4. The meta-trial as a pragmatic solution for efficient pandemic clinical research

In order to combine the benefits of international research with the fast setup of national trials, we propose to coordinate multiple national investigator-initiated trials in the form of a prospective meta-analysis. This so-called “meta-trial” consists of aggregating data from various national trials during the data collection [8]. To study prone positioning in awake patients with COVID-19 pneumonia, two such trials were registered on clinicaltrials.gov (one in the USA, the other in France) in mid-march 2020, and the investigators got in contact with 3 other groups planning trials with very similar inclusion and outcome criteria in Canada, Ireland and Spain, who all joined the meta-trial project. Each trial could be set up within a few weeks given the accelerated procedures in place during the COVID-19 outbreak. Planned sample sizes of individual trials ranged from 198 to 346 patients with the total planned inclusion of 1386 patients across 5 countries. Investigators and methodologists of all groups organized several web meetings to harmonize inclusion of 1386 patients across 5 countries. Investigators and methodologists of all groups organized several web meetings to harmonize inclusion criteria and primary and secondary outcomes of the meta-trial. Given the planned sample sizes, an interim analysis plan was developed at the meta-trial level analyzing aggregated data every 200 patients. A memorandum of understanding and data sharing agreement were drafted (available upon request).

The meta-trial concept enables researchers to combine the agility of smaller national trials into a much larger international project in a short period of time (Table 1). Meta-trial interim analysis enables to detect a positive or negative response to the scientific question as soon as an adequate sample size is reached across several countries, thus potentially speeding up the research process dramatically [9,10]. Adherence to methodological standards of individual trials represents a guarantee of a high level of overall final quality. Furthermore, by estimating the treatment effect across the various trials upfront, the meta-trial may provide stronger evidence in favor of external validity and replicability of the individual trials.

To the best of our knowledge, the meta-trial concept has never been experienced in real life across several countries, and feasibility uncertainties do exist. The present project may serve as a guidance for future research projects set up in a pandemic context.

5. How to join

The meta-trial is a living project in the sense that other groups can join as long as they adhere to the general principle and abide by ethical regulations in their country. Protocols and clinical record files are made available upon request by the core investigator group of the meta-trial. Readers are invited to contact authors for any additional information and to join the project (Awake.Prone.Meta.Trial@gmail.com).

Authors contributions

ET, JL and SE initially designed the project, SE drafted the manuscript, all authors contributed significantly to study design and concept, all authors reviewed the manuscript for important intellectual content.

Financial disclosure

This work was supported by OpenAl, (3180 18th St, San Francisco, CA 94110, United States), Fisher & Paykel (15 Maurice Paykel Place, East Tamaki, Auckland 2013 New Zealand), Rice Foundation (8600 Gross Point Rd, Skokie, IL 60077, United States) and the French Ministry of Health (Appel d‘offre PHRC inter-régional GIRC1 grand-ouest).

Declaration of Competing Interest

JL discloses research support from Fisher & Paykel Healthcare for another research project. IP has been a speaker for Fisher & Pakyel.
Healthcare within the last 3 years. All compensation was paid to the charitable foundation at the hospital where he works, and he did not personally receive any compensation. OR provides consultancy to Hamilton Medical but he did not receive any personal fee. All compensations were received by the Institute of Research of his Institution. He received speaker fees by Air Liquide. SE received unrestricted research grants, travel fee reimbursements and speaker fees from Fisher & Paykel Healthcare, consulting fees from La Diffusion Technique Française, consulting fees and unrestricted research grants from Aerogen Ltd., and an unrestricted research grant from Hamilton medical. Other authors have no conflict of interest to declare.
