ON THE TOPOLOGY OF SURFACE SINGULARITIES \{z^n = f(x,y)\}, FOR f IRREDUCIBLE

ELIZABETH A. SELL

Abstract. The splice quotients are an interesting class of normal surface singularities with rational homology sphere links, defined by W. Neumann and J. Wahl. If \(\Gamma\) is a tree of rational curves that satisfies certain combinatorial conditions, then there exist splice quotients with resolution graph \(\Gamma\). Suppose the equation \(z^n = f(x,y)\) defines a surface \(X_{f,n}\) with an isolated singularity at the origin in \(\mathbb{C}^3\). For \(f\) irreducible, we completely characterize, in terms of \(n\) and a variant of the Puiseux pairs of \(f\), those \(X_{f,n}\) for which the resolution graph satisfies the combinatorial conditions that are necessary for splice quotients. This result is topological; whether or not \(X_{f,n}\) is analytically isomorphic to a splice quotient is treated separately.

1. Introduction

Let \((X, 0) \subset (\mathbb{C}^k, 0)\) be the germ of a complex analytic normal surface singularity. The intersection of \(X\) with a sufficiently small sphere centered at the origin in \(\mathbb{C}^k\) is a compact connected oriented three-manifold \(\Sigma\), called the link of \((X, 0)\), that does not depend upon the embedding in \(\mathbb{C}^k\). Let \(\Gamma\) be the dual resolution graph of a good resolution of the singularity. The homeomorphism type of the link can be recovered from \(\Gamma\), and conversely, W. Neumann proved that (aside from a few exceptions) the homeomorphism type of the link determines the minimal good resolution graph [8]. One interesting class of normal surface singularities is the set of those for which the link is a rational homology sphere (QHS) (i.e., \(H_1(\Sigma, \mathbb{Q}) = 0\)). The link is a QHS if and only if any good resolution graph \(\Gamma\) of \((X, 0)\) is a tree of rational curves.

The work of Neumann and Wahl (described in §2; see also [10] and [18]) provides a method for generating analytic data for singularities from topological data. Starting with a resolution graph \(\Gamma\) that satisfies certain conditions, known as the “semigroup and congruence conditions”, one can produce defining equations for a normal surface singularity with resolution graph \(\Gamma\). The singularities that result from this algorithm are called splice quotients. If the link \(\Sigma\) is a ZHS (\(H_1(\Sigma, \mathbb{Z}) = 0\)), then only the semigroup conditions are relevant, and the singularities produced by the algorithm are said to be of splice type. This work has led to a recent interest in the properties of splice quotients and related topics (see [3], [6], [13], [14], [17]), and there are still many unanswered questions.

One of the first questions that arises is: How many singularities with QHS link are splice quotients? There are two layers to the problem - topological and analytic. If one has a singularity that satisfies the necessary topological conditions (which depend only on the resolution graph), then there exist splice quotients with that topological type, but it is a separate issue to determine whether the singularity is analytically isomorphic to a splice quotient. Originally, one wondered whether all \(\mathbb{Q}\)-Gorenstein singularities with QHS link would turn out to be splice quotients. However, the first counterexamples were found in the paper of I. Luengo-Velasco, A. Melle-Hernández, and A. Némethi [3]. There, the authors give an example of a hypersurface singularity for which the resolution graph does not satisfy the semigroup conditions, and an example of a singularity for which the semigroup and congruence conditions are satisfied, but the analytic type is not a splice quotient. On the other hand, there are nice classes of singularities for which all analytic types are splice quotients: weighted homogeneous singularities, as shown by Neumann in [7], and rational and QHS-link minimally elliptic singularities, as shown by T. Okuma in [13].

A natural class of surface singularities to study after weighted homogeneous, rational, and minimally elliptic is the class of hypersurface singularities defined by an equation of the form \(z^n = f(x,y)\). If \(\{f(x,y) = 0\}\) defines a reduced curve with a singularity at the origin in \(\mathbb{C}^2\), then for \(n > 1\), the

Date: June 30, 2009.
surface $X_{f,n} := \{ z^n = f(x,y) \}$ has an isolated (hence normal) singularity at the origin in $\mathbb{C}^3$. For $f$ irreducible, the resolution graph of $(X_{f,n},0)$ can be constructed from $n$ and a finite set of pairs of positive integers associated to $f$, known as the topological pairs $\{ (p_i, a_i) \mid 1 \leq i \leq s \}$ defined in [2] (a variant of the more commonly known Puiseux pairs). The topological pairs completely determine the topology of the plane curve singularity. If there is only one topological pair ($s = 1$), then any such $(X_{f,n},0)$ with QHS link has the topological type of a weighted homogeneous singularity, hence has the topological type of a splice quotient. In [2], Neumann and Wahl prove that the link of $(X_{f,n},0)$ is a ZHS if and only if $f$ is irreducible and all $p_i$ and $a_i$ are relatively prime to $n$ and in that case, they prove in [12] that any such $(X_{f,n},0)$ is of splice type. That is, not only are the semigroup conditions satisfied, but moreover, every $(X_{f,n},0)$ with ZHS link is isomorphic to one that results from Neumann and Wahl’s construction.

The main result of this paper is a complete characterization of the $(X_{f,n},0)$, with $f$ irreducible and $s \geq 2$, that have a resolution graph that satisfies the semigroup and congruence conditions. For $f$ irreducible, there is an explicit criterion given by R. Mendris and Némethi in [4], in terms of $n$ and the topological pairs, that determines when the link of $(X_{f,n},0)$ is a QHS (see Proposition 3.2).

One can see that there are plenty of $(X_{f,n},0)$ for which the link is a QHS but not a ZHS. From now on, whenever we are not referring to topological pairs, the notation $(m, n)$ denotes the greatest common divisor of the integers $m$ and $n$. Our main result is the following

**Main Theorem.** Let $f$ be irreducible with topological pairs $\{ (p_i, a_i) : 1 \leq i \leq s \}$, with $s \geq 2$, and let $n$ be an integer greater than 1. Then $(X_{f,n},0)$ has QHS link and a good resolution graph that satisfies the semigroup and congruence conditions if and only if either

1. $(n, p_1) = 1$, $(n, p_i) = (n, a_i) = 1$ for $1 \leq i \leq s - 1$, and $a_s/(n, a_s)$ is in the semigroup generated by $(a_s - 1, p_1 \cdots p_{s-1}, a_2 p_{j+1} \cdots p_{s-1} : 1 \leq j \leq s - 2)$, or
2. $s = 2$, $p_2 = 2$, $(n, p_2) = 2$, and $(n, a_2) = (n, a_1) = 1$.

It is somewhat surprising that so few $(X_{f,n},0)$ satisfy the topological conditions, given the result in the ZHS case. Aside from Case (ii), which is rather restrictive, this result says that if any of the topological pairs other than $a_s$ have factors in common with $n$, then $(X_{f,n},0)$ does not have the topological type of a splice quotient. One could say that if $(X_{f,n},0)$ gets “too far” from the ZHS case (for which all analytic types are splice quotients), it cannot even have the topology of a splice quotient.

If the resolution graph does satisfy the semigroup and congruence conditions, a priori we do not know what the equations of the splice quotients produced from the Neumann-Wahl algorithm look like. Not only is it unclear whether or not $(X_{f,n},0)$ itself is a splice quotient, but in fact, it is not even clear that there exist splice quotients defined by any equation of the form $z^n = g(x, y)$. It turns out that there do exist such splice quotients; unfortunately, the length of the proof is such that it cannot be included here. That result can be found in [15]. In the case of weighted homogeneous splice quotients, it was shown in [16] that in general, not every deformation with the same topological type is analytically isomorphic to a splice quotient. Therefore, we expect that there are few cases for which every $(X_{f,n},0)$ of a given topological type is a splice quotient.

Consider the following example.

**Example 1.1.** Let $X_n := \{ z^n = y^5 + (x^3 + y^2)^2 \}$. The plane curve singularity defined by $y^5 + (x^3 + y^2)^2 = 0$ is irreducible with two topological pairs, $p_1 = 2$, $a_1 = 3$, $p_2 = 2$, and $a_2 = 15$. The link of $(X_n,0)$ is a QHS if and only if either $(n, 2) = 1$ or $(n, 15) = 1$. We can say the following about $X_n$:

- If $n$ is relatively prime to 2, 3, and 5, then $(X_n,0)$ has ZHS link and hence is of splice type.
- If $n$ is divisible by 3, the Main Theorem says that $(X_n,0)$ does not even have the topological type of a splice quotient.
- If $n$ is divisible by 3, the Main Theorem says that $(X_n,0)$ does not even have the topological type of a splice quotient.
- If $n = 5k$, where $k$ is relatively prime to 2 and 3, then $(X_n,0)$ has the topology of a splice quotient by Case (i) of the Main Theorem, and in fact, $(X_n,0)$ is itself a splice quotient [16].

\(^1\)In [2], the result is incorrectly stated. The pairs in question are mistakenly identified as the Newton pairs instead of the topological pairs.
• If \( n = 2k \), where \( k \) is relatively prime to 2, 3, and 5, then \( (X_n,0) \) has the topology of a splice quotient by Case (ii) of the Main Theorem. It is unclear whether or not \( (X_n,0) \) is a splice quotient. However, if we replace \( y^5 + (x^3 + y^2)^2 \) by \((x^3 - y^2 - y^3)^2 - 4y^5 \), which has the same topological pairs, it is a splice quotient \(10\).

The rest of this paper is entirely devoted to proving the Main Theorem. In section 2, we provide a brief summary of the work of Neumann and Wahl. Section 3 contains a description of the resolution graph and splice diagram for \( (X_{f,n},0) \). Some of the computations that are necessary for the proof of the Main Theorem depend upon work done by Mendris and Némethi in \([4]\); section 5.1 is a reiteration of this material. In section 4, we analyze the semigroup conditions for the splice diagram associated to \( (X_{f,n},0) \). Section 5 contains additional computations that are needed for checking the congruence conditions. Finally, in section 6, we use the computations from the previous three sections to prove the Main Theorem.

Acknowledgements. Special thanks are due to J. Wahl for many very helpful conversations throughout the preparation of this work.

2. The Neumann-Wahl algorithm

This section contains a summary of the method defined by Neumann and Wahl in \([11]\) to produce equations for the splice quotients and their universal abelian covers; we refer to this method as the Neumann-Wahl algorithm. The algorithm begins with a negative-definite graph \( \Gamma \) that is a tree of smooth rational curves (equivalently, the dual resolution graph associated to a good resolution of a normal surface singularity with QHS link) and the splice diagram \( \Delta \) associated to \( \Gamma \). Splice diagrams were introduced by Eisenbud and Neumann \([2]\) for plane curve singularities (building on work of Siebenmann), and later generalized by Neumann and Wahl. If \( \Delta \) satisfies the “semigroup conditions” (Definition 2.1), then the algorithm produces a set of equations that defines a family of isolated complete intersection surface singularities. The algorithm also produces an action of the finite abelian group \( D(\Gamma) \), the discriminant group of \( \Gamma \), on the coordinates used for the splice diagram equations. If \( \Gamma \) satisfies further combinatorial conditions, the “congruence conditions” (Definition 2.3), then one can choose a set of splice diagram equations such that the discriminant group acts on every singularity \( (Y,0) \) in the family. Furthermore, the quotient of \( (Y,0) \) by \( D(\Gamma) \) is an isolated normal surface singularity with resolution graph \( \Gamma \), and the covering given by the quotient map is the universal abelian covering (the maximal abelian covering that is unramified away from the singular point).

In a weighted graph, the valency of a vertex is the number of adjacent edges. A node is a vertex of valency at least three, a leaf is a vertex of valency one, and a string is a connected subgraph that does not include a node. The procedure for computing the splice diagram \( \Delta \) associated to a resolution graph \( \Gamma \) is as follows. First, omit the self-intersection numbers of the vertices and contract all strings of valency two vertices in \( \Gamma \). To each node \( v \) in the resulting diagram \( \Delta \), attach a weight \( d_{ve} \) in the direction of each adjacent edge \( e \). Remove the vertex in \( \Gamma \) that corresponds to the node \( v \) and the edge that corresponds to \( e \), and let \( \Gamma_{ve} \) be the remaining connected subgraph that was connected to \( v \) by \( e \). Then the weight \( d_{ve} = \det(-C_{ve}) \), where \( C_{ve} \) is the intersection matrix of the graph \( \Gamma_{ve} \). Figure 1 contains a simple example. Similarly, we define a subgraph \( \Delta_{ve} \) of \( \Delta \) as follows. Remove \( v \) and \( e \), and let \( \Delta_{ve} \) be the remaining connected subgraph that was connected to \( v \) by \( e \). For any two vertices \( v \) and \( w \) in \( \Delta \), the linking number \( \ell_{vw} \) is the product of the weights adjacent to but not on the shortest path from \( v \) to \( w \). Let \( \ell'_{vw} \) be the linking number of \( v \) and \( w \), excluding the weights around \( v \) and \( w \).

![Figure 1. A resolution graph \( \Gamma \) and its associated splice diagram \( \Delta \).](image-url)
Definition 2.1 (Semigroup Conditions). The semigroup condition at \( v \) in the direction of \( e \) is
\[
d_{ve} \in \mathbb{N}(\ell_{vw}^e \mid w \text{ is a leaf in } \Delta_{ve}).
\]
We say that \( \Delta \) satisfies the semigroup conditions if the semigroup condition for every node \( v \) and every adjacent edge \( e \) is satisfied. Note that for an edge leading to a leaf, the condition is trivially satisfied.

To each leaf \( w \) in \( \Delta \), associate a variable \( Z_w \). If \( \Delta \) satisfies the semigroup conditions, then for each \( v \) and \( e \) as above, there exist \( \alpha_{vw} \in \mathbb{N} \cup \{0\} \) such that
\[
d_{ve} = \sum_{w \text{ a leaf in } \Delta_{ve}} \alpha_{vw} \ell_{vw}^e.
\]
Then a monomial \( M_{ve} = \prod_w Z_w^{\alpha_{vw}}, \) a product over leaves \( w \) in \( \Delta_{ve} \) with \( \alpha_{vw} \) as above, is called an admissible monomial for \( e \) at \( v \). If one associates the weight \( \ell_{vw} \) to \( Z_w \), then for this weight system, the so-called \( v \)-weighting, \( M_{ve} \) has weight \( d_v = \prod_e d_{ve} \), where the product is taken over all edges \( e \) adjacent to \( v \).

Definition 2.2 (Splice Diagram Equations). Suppose \( \Delta \) satisfies the semigroup conditions. For each node \( v \) and adjacent edge \( e \), choose an admissible monomial \( M_{ve} \). Let \( \delta_v \) denote the valency of the vertex \( v \). A set of splice diagram equations for \( \Delta \) is a set of equations of the form
\[
\left\{ \sum_e a_{ve} M_{ve} = 0 : 1 \leq i \leq \delta_v - 2, \, v \text{ a node in } \Delta \right\},
\]
where for each \( v \), all maximal minors of the matrix (\( a_{ve} \)) have full rank. (One can also add to each equation a convergent power series in the \( Z_w \) for which all of the terms have \( v \)-weight greater than \( d_v \). Since this extension has no bearing upon the work herein, we omit it in further discussion.)

Each vertex \( v \in \Gamma \) corresponds to an exceptional curve \( E_v \). Let \( E := \bigoplus_{v \in \Gamma} Z E_v \). The intersection pairing defines a natural injection \( E \hookrightarrow E^* = \text{Hom}(E, \mathbb{Z}) \), and the discriminant group is the finite abelian group \( D(\Gamma) := E^*/E \). This group is isomorphic to \( H_2(\Sigma, \mathbb{Z}) \). The order of \( D(\Gamma) \) is \( \det(\Gamma) := \det(-C(\Gamma)) \), where \( C(\Gamma) : E \times E \rightarrow \mathbb{Z} \) is the intersection pairing. There are induced symmetric pairings of \( E \otimes \mathbb{Q} \) into \( \mathbb{Q} \) and \( D(\Gamma) \) into \( \mathbb{Q} \).

Suppose \( \Delta \) has \( t \) leaves, and let \( Z_1, \ldots, Z_t \) be the associated variables. Neumann and Wahl define a faithful diagonal representation of \( D(\Gamma) \) on \( \mathbb{C}[Z_1, \ldots, Z_t] \). Let \( E_1, \ldots, E_t \) be the curves in \( \Gamma \) corresponding to the \( t \) leaves of \( \Delta \), and let \( e_j \in E^* \) be the dual basis element corresponding to \( E_j \). That is, \( e_j(E_k) = \delta_{jk} \). Finally, for \( r \in \mathbb{Q} \), let \( [r] \) denote the image of the equivalence class of \( r \) under the map \( \mathbb{Q}/\mathbb{Z} \hookrightarrow \mathbb{C}^* \) defined by \( r \mapsto \exp(2\pi i r) \). Then the action of the discriminant group on the polynomial ring \( \mathbb{C}[Z_1, \ldots, Z_t] \) is generated by the action of the \( e_j \), \( 1 \leq j \leq t \), which is defined by \( e_j \cdot Z_k = [-e_j \cdot e_k] Z_k, 1 \leq j, k \leq t \), where \( \cdot \) denotes the action.

Definition 2.3 (Congruence conditions). Let \( \Gamma \) be a graph for which the associated splice diagram \( \Delta \) satisfies the semigroup conditions. Then we say that \( \Gamma \) satisfies the congruence condition at a node \( v \) if one can choose an admissible monomial for each adjacent edge \( e \) such that all of these monomials transform by the same character under the action of \( D(\Gamma) \). If this condition is satisfied for every node \( v \), then \( \Gamma \) satisfies the congruence conditions.

We should mention here that Okuma gives a single condition that is equivalent to the semigroup and congruence conditions together, “Condition 3.3” of [13]. That this condition is equivalent to the semigroup and congruence conditions is shown in [11]. We will often say “\( \Gamma \) satisfies the semigroup and congruence conditions”, as opposed to “\( \Delta \) satisfies the semigroup conditions and \( \Gamma \) satisfies the congruence conditions”. Suppose a resolution graph \( \Gamma \) satisfies the semigroup and congruence conditions. Then, by a set of splice diagram equations for \( \Gamma \), we mean equations as in Definition 2.1 such that for each \( v \), the admissible monomials \( M_{ve} \) transform equivariantly under \( D(\Gamma) \). A resolution tree \( \Gamma \) is quasi-minimal if any string in \( \Gamma \) either contains no \((-1)\)-weighted vertex, or consists of a unique \((-1)\)-weighted vertex.

Theorem 2.4 ([11]). Suppose \( \Gamma \) is quasi-minimal and satisfies the semigroup and congruence conditions. Then a set of splice diagram equations for \( \Gamma \) defines an isolated complete intersection
singularity \((Y, 0)\), \(D(\Gamma)\) acts freely on \(Y - \{0\}\), and the quotient \(X := Y/D(\Gamma)\) has an isolated normal surface singularity and a resolution with dual resolution graph \(\Gamma\). Moreover, \((Y, 0) \rightarrow (X, 0)\) is the universal abelian cover.

We will use the next two propositions to check the congruence conditions.

**Proposition 2.5 (11).** Let \(\Gamma\) be a graph for which the associated splice diagram \(\Delta\) satisfies the semigroup conditions. Then the congruence conditions are equivalent to the following: For every node \(v\) and adjacent edge \(e\) in \(\Delta\), there is an admissible monomial \(M_{ve} = \prod w Z_w^a\) such that for every leaf \(w^\prime\) in \(\Delta_{w^\prime}\),

\[
\sum_{w \neq w^\prime} \alpha_w \frac{\ell_{ww^\prime}}{\det(\Gamma)} - \alpha_{w^\prime} e_{w^\prime} = \left[ \frac{e_{w^\prime}}{\det(\Gamma)} \right].
\]

**Remark 2.6.** It is easy to check, using the following proposition, that this condition is always satisfied for an edge leading directly to a leaf.

**Proposition 2.7 (11).** Suppose we have a string from a leaf \(w\) to an adjacent node \(v\) in a resolution graph \(\Gamma\) as in the following diagram, with associated continued fraction \(d/p\).

\[
-\bullet -k_1 \quad -\bullet -k_2 \quad -\bullet -k_s \quad \bullet v
\]

That is,

\[
\frac{d}{p} = k_1 - \frac{1}{k_2 - \frac{1}{\ddots \frac{1}{k_s}}}
\]

Then, if \(d_v\) is the product of weights at \(v\), \(e_w \cdot e_w = -d_v/(d^2 \det(\Gamma)) - p/d\).

### 3. The resolution graph and splice diagram

Let \(\{f(x, y) = 0\} \subset \mathbb{C}^2\) define an analytically irreducible plane curve with a singularity at the origin, and let \(X_{f,n} := \{z^n = f(x, y)\} \subset \mathbb{C}^3\). In [4], Mendris and Némethi prove that the link of \((X_{f,n}, 0)\) completely determines the Newton/topological pairs of \(f\) and the value of \(n\), with two well-understood exceptions. In doing so, they give a presentation of the construction of the resolution graph of \((X_{f,n}, 0)\) that is very useful for our purposes. Section 3.1 is a summary of the results we need from Mendris and Némethi’s work, and we use their notation whenever possible. In section 3.2 we describe the associated splice diagram.

It turns out that when \(n = p_s = 2\), the resolution graph has a structure that differs significantly from the general case. It is referred to as the “pathological case” or “P-case” by Mendris and Némethi, and we use this terminology as well. Some of the computations must be done separately for the pathological case.

**3.1. Resolution graph.** Suppose that \(f\) has Newton pairs \(\{(p_k, q_k) \mid 1 \leq k \leq s\}\) (see [2], p. 49). They satisfy the following properties: \(q_1 > p_1\), \(q_k \geq 1\), \(p_k \geq 2\), and \(\gcd(p_k, q_k) = 1\) for all \(k\). Define integers \(a_k\) by \(a_1 = q_1\), and

\[
a_k = q_k + a_{k-1}p_{k-1}p_k, \quad 2 \leq k \leq s.
\]

The pairs \(\{(p_k, a_k) \mid 1 \leq k \leq s\}\), defined by Eisenbud and Neumann in [2], are referred to as the topological pairs of \(f\). These are the integers that appear in the splice diagram of the link of the plane curve singularity defined by \(f = 0\) in \(\mathbb{C}^2\). Note that \(a_1 > p_1\), \(a_k > a_{k-1}p_{k-1}p_k\), and \(\gcd(p_k, a_k) = 1\) for all \(k\).

The topological pairs \(\{(p_k, a_k) \mid 1 \leq k \leq s\}\) are related to the Puiseux pairs \(\{(p_k, m_k) \mid 1 \leq k \leq s\}\) as follows: \(a_1 = m_1\), and \(a_k = m_k - m_{k-1}p_k + a_{k-1}p_{k-1}p_k\), for \(2 \leq k \leq s\). Furthermore, let \(\beta_k\), \(0 \leq k \leq s\), be the generators of the semigroup associated to the plane curve singularity defined by \(f\) (see [19]). Then we have \(\beta_0 = p_1p_2\cdots p_s\), \(\beta_k = a_kp_{k+1}\cdots p_s\) for \(1 \leq k \leq s - 1\), and \(\beta_s = a_s\).

By an embedded resolution of the germ of a function \(g : (X, 0) \rightarrow (\mathbb{C}, 0)\) we mean a resolution of the singularity \(\pi : \tilde{X} \rightarrow X\) such that \(\pi^{-1}(\{g = 0\})\) is a divisor with only normal crossing
singularities. We also assume that no irreducible component of the exceptional set \( \pi^{-1}(0) \) intersects itself and that any two irreducible components have at most one intersection point. The minimal good embedded resolution graph of \( f : (\mathbb{C}^2, 0) \rightarrow (\mathbb{C}, 0) \) is a tree of rational curves, denoted \( \Gamma(\mathbb{C}^2, f) \).

The construction of the graph \( \Gamma(\mathbb{C}^2, f) \) is well-known (e.g., [1]). Reproducing the notation of Mendris and Némethi [3], we consider this graph in a convenient schematic form (Figure 2), where the dashed lines represent strings of rational curves (possibly empty) for which the self-intersection numbers are determined by the continued fraction expansions of \( p_k/q_k \) and \( q_k/p_k \) (see [3,2] for details).

![Figure 2. Schematic form of \( \Gamma(\mathbb{C}^2, f) \), reproduced from [4].](image)

There is an algorithm for constructing an embedded resolution graph (not necessarily minimal) of the function \( z : (X_{f,n}, 0) \rightarrow (\mathbb{C}, 0) \) from the graph \( \Gamma(\mathbb{C}^2, f) \). Here, we follow the presentation in [4], reproducing only what is necessary for our purposes. The output of this algorithm, without any modifications by blow up or down, is referred to by Mendris and Némethi as the canonical embedded resolution graph of \( z \) in \( (X_{f,n}, 0) \), and is denoted \( \Gamma^{can}(X_{f,n}, z) \). The \( n \)-fold "covering" or "graph projection" produced in the algorithm is denoted \( q : \Gamma^{can}(X_{f,n}, z) \rightarrow \Gamma(\mathbb{C}^2, f) \).

**Definition 3.1 ([4]).** Define positive integers \( d_k, h_k, \tilde{h}_k, p'_k, \) and \( a'_k \) as follows:

\[
\begin{align*}
\bullet & \quad d_k = (n, p_{k+1}p_{k+2}\cdots p_s) \quad \text{for } 0 \leq k \leq s - 1, \\
\bullet & \quad d_s = 1;
\end{align*}
\]

and, for \( 1 \leq k \leq s, \)

\[
\begin{align*}
\bullet & \quad h_k = (p_k, n/d_k), \\
\bullet & \quad \tilde{h}_k = (a_k, n/d_k), \\
\bullet & \quad p'_k = p_k/h_k, \\
\bullet & \quad a'_k = a_k/\tilde{h}_k.
\end{align*}
\]

If \( w \) is a vertex in \( \Gamma(\mathbb{C}^2, f) \), then all vertices in \( q^{-1}(w) \) have the same multiplicity and genus, which we denote \( m_w \) and \( g_w \), respectively.

**Proposition 3.2 ([4]).** Let \( q : \Gamma^{can}(X_{f,n}, z) \rightarrow \Gamma(\mathbb{C}^2, f) \) be the "graph projection" mentioned above. Then \( \Gamma^{can}(X_{f,n}, z) \) is a tree such that the following hold:

\[
\begin{align*}
(a) & \quad \#q^{-1}(v_k) = 1 \quad \text{for } 0 \leq k \leq s - 1, \\
& \quad \#q^{-1}(v_s) = h_{k+1}\cdots h_s, \quad (1 \leq k \leq s - 1) \\
& \quad \#q^{-1}(\bar{v}_k) = h_k \cdots h_s; \\
(b) & \quad m_{\bar{v}_k} = \tilde{a}'_k \tilde{p}_k \tilde{p}'_{k+1} \cdots \tilde{p}_s, \\
& \quad m_{v_k} = a'_k p_k \cdot \cdots \cdot p_s, \quad (1 \leq k \leq s), \\
& \quad m_{\bar{v}_s} = a'_k, \\
& \quad m_{v_s} = \tilde{h}_k, \\
(c) & \quad g_{\bar{v}_k} = 0, \quad (0 \leq k \leq s), \\
& \quad g_{v_k} = (h_k - 1)(\tilde{h}_k - 1)/2, \quad (1 \leq k \leq s) .
\end{align*}
\]

In particular, the link of \( (X_{f,n}, 0) \) is a QHS if and only if \( (h_k - 1)(\tilde{h}_k - 1) = 0 \) for all \( k, 1 \leq k \leq s \).

The schematic form of \( \Gamma^{can}(X_{f,n}, z) \) is displayed in Figure 3, which is reproduced from [4]. Abusing notation, we have labelled any vertex in \( q^{-1}(v_k) \) (respectively, \( q^{-1}(\bar{v}_k) \)) with \( v_k \) (respectively, \( \bar{v}_k \)). The dashed lines represent strings of vertices that are not necessarily minimal. By the construction, each string must contain at least as many vertices as its image in \( \Gamma(\mathbb{C}^2, f) \). A vertex is called a rupture vertex if either it has positive genus or it is a node. Note that any rupture vertex of \( \Gamma^{can}(X_{f,n}, z) \) must be in \( q^{-1}(v_k) \) for some \( k \).
Certain subgraphs of $\Gamma_{\text{can}}(X_{f,n}, z)$ and their determinants. Let $w$ be a vertex in $\Gamma(\mathbb{C}^2, f)$, and let $v'$ be any vertex in $q^{-1}(w)$. If $w = v_k$ for some $k$, $1 \leq k \leq s - 1$, then the shortest path from $v'$ to the arrowhead of $\Gamma_{\text{can}}(X_{f,n}, z)$ contains at least one rupture vertex, and the rupture vertex along that path which is closest to $v'$ is a vertex $v'' \in q^{-1}(v_{k+1})$. Define $\Gamma(v')$ to be the subgraph of $\Gamma_{\text{can}}(X_{f,n}, z)$ consisting of the string of vertices between $v'$ and $v''$, not including $v'$ and $v''$. If $w = v_s$, then the shortest path from $v'$ to the arrowhead is a string; let $\Gamma(v')$ be this string, not including $v'$. Finally, if $w = v_k$, $0 \leq k \leq s$, let $v''$ be the rupture vertex that is closest to $v'$ on the shortest path from $v'$ to the arrowhead. Define $\Gamma(v')$ to be the subgraph of consisting of the string of vertices from $v'$ to $v''$, including $v'$ but not $v''$. Up to isomorphism, none of these strings depend upon the choice of $v'$ in $q^{-1}(w)$, so whenever the particular vertex $v'$ does not matter, we will simply denote them $\Gamma(w)$.

Fix an integer $k$, $1 \leq k \leq s$, and fix a vertex $v'$ in $q^{-1}(v_k)$. Consider the collection of connected subgraphs that make up $\Gamma_{\text{can}}(X_{f,n}, z) - \{v'\}$. There are $h_k$ isomorphic components that are strings of isomorphism type $\Gamma(v_k)$. There is one connected subgraph that contains the arrowhead; denote this subgraph $\Gamma_A(v')$. The $h_k$ remaining components are all isomorphic. Let $\Gamma_-(v')$ denote any of these isomorphic subgraphs. Again, whenever the particular choice of $v'$ is unimportant, we use $\Gamma_-(v_k)$.
instead of \( \Gamma_-(v') \), and \( \Gamma_A(v_k) \) instead of \( \Gamma_A(v') \). Note that \( \Gamma_-(v_1) = \Gamma(\overrightarrow{v_0}) \) and \( \Gamma_A(v_s) = \Gamma(v_s) \). We should also point out that the subgraphs \( \Gamma_A(v_k) \) do not appear in \([4]\); in particular, \( \Gamma_A(v_k) \) is not the same as their \( \Gamma_+(v_k) \).

For any resolution graph \( \Gamma \), let \( \det(\Gamma) := \det(-C) \), where \( C \) is the intersection matrix of the exceptional curves in \( \Gamma \). If \( \Gamma \) is empty, then we define \( \det(\Gamma) \) to be 1. Nearly all of the determinants of the subgraphs defined above are explicitly computed by Mendris and Némethi in \([4]\), and those that are not can be computed by the same method.

**Lemma 3.3** \([4]\). For any \( w \) in \( \Gamma(\mathbb{C}^2, f) \) as above, let \( D(w) := \det(\Gamma(w)) \). Then

\[
\begin{align*}
D(\overrightarrow{v_0}) &= a_1', \\
D(\overrightarrow{v_k}) &= p'_k, \text{ for } 1 \leq k \leq s, \\
D(v_s) &= n(h_s h_s), \\
D(v_k) &= n h_{k+1}/(d_k h_{k+1}), \text{ for } 1 \leq k \leq s-1.
\end{align*}
\]

It follows from the construction of \( \Gamma^{can}(X_{f,n}, z) \) that if \( D(v_s) = 1 \), this indicates that \( \Gamma(v_s) \) is empty, and the arrowhead in \( \Gamma^{can}(X_{f,n}, z) \) is connected directly to the unique vertex in \( q^{-1}(v_s) \).

**Lemma 3.4** \([4]\). Let \( D_-(v_k) := \det(\Gamma_-(v_k)) \), \( 1 \leq k \leq s \). If \( s \geq 2 \), then for \( 2 \leq k \leq s \),

\[
\frac{D_-(v_k)}{a_k'} = (a'_k h_{k-1}^{-1} h_{k-1}^{-1} D_-(v_{k-1}))^{h_{k-1}}.
\]

The method used to prove Lemma 3.4 can be suitably modified to prove the next two lemmas. The computation is straightforward, so we omit the proof.

**Lemma 3.5.** Assume \( s \geq 2 \), and let \( D_A(v_k) := \det(\Gamma_A(v_k)) \), \( 1 \leq k \leq s \). Let \( A_k \) be defined recursively by \( A_{k-1} = a_{s-1} p_{s-1} + q_s \), and, for \( 1 \leq k \leq s-2 \),

\[
A_k = a_k p_k p_{k+1} + q_k + a_{k+2} \cdots a_s.
\]

Then

\[
D_A(v_k) = \frac{n A_k \prod_{j=k+1}^s (p'_j h^{-1} D_-(v_j))^{h_j-1}}{h_k h_{k+1}, \cdots, a_s}, \text{ for } 1 \leq k \leq s-1.
\]

**Lemma 3.6.** The determinant of \( \Gamma^{can}(X_{f,n}, z) \) is given by

\[
\det(\Gamma^{can}(X_{f,n}, z)) = (a'_s h^{-1} p'_s h^{-1})^{h_s} \left[ \frac{D_-(v_s)}{a'_s} \right]^{h_s}.
\]

A minimal good embedded resolution graph of \( z \) in \( (X_{f,n}, 0) \), denoted \( \Gamma^{min}(X_{f,n}, z) \), is obtained from \( \Gamma^{can}(X_{f,n}, z) \) by repeatedly blowing down any rational \((-1)\)-curves for which the corresponding vertex has valency one or two. By dropping the arrowhead and multiplicities of \( \Gamma^{min}(X_{f,n}, z) \) and then blowing down any appropriate rational \((-1)\)-curves, we obtain a minimal good resolution graph of \( (X_{f,n}, 0) \), denoted \( \Gamma^{min}(X_{f,n}) \).

**Proposition 3.7** \([4]\). All of the rupture vertices in \( \Gamma^{can}(X_{f,n}, z) \) survive as rupture vertices in \( \Gamma^{min}(X_{f,n}, z) \). That is, they are not blown down in the minimization process, and after minimization, they are still rupture vertices.

**Proposition 3.8** \([4]\). Assume that by deleting the arrowhead of \( \Gamma^{min}(X_{f,n}, z) \) we obtain a non-minimal graph. This situation can happen if and only if \( n = p_s = 2 \). In this case, the line is a QHS and \( \Gamma^{min}(X_{f,n}, z) \) has the following schematic form, with \( e \geq 3 \).
The minimal resolution graph $\Gamma_{\text{min}}(X_{f,n})$ is obtained from $\Gamma_{\text{can}}(X_{f,n}, z)$ by deleting the arrowhead and blowing down $v$.

Propositions 3.4 and 3.5 imply that all of the nodes in $\Gamma_{\text{can}}(X_{f,n}, z)$ remain nodes in the minimal good resolution graph of $(X_{f,n}, 0)$ except in the case $n = p_s = 2$. We refer to $n = p_s = 2$ as the pathological case, and it is treated separately in what follows.

3.2. Splice diagram. From now on, we assume that the link of $(X_{f,n}, 0)$ is a QHS. That is, for each $k$, $1 \leq k \leq s$, either $h_k$ or $\tilde{h}_k$ is equal to 1. One complication that arises is that certain strings in $\Gamma_{\text{can}}(X_{f,n}, z)$ may completely collapse upon minimalization. Therefore, if we use the minimal good resolution graph $\Gamma_{\text{min}}(X_{f,n})$ in what follows, we would constantly need to note that certain strings may be empty, and more importantly, that certain leaves in the splice diagram may not be present. We will avoid this by using the splice diagram associated to $\Gamma_{\text{min}}(X_{f,n})$, the graph that results from deleting the arrowhead and multiplicities in $\Gamma_{\text{can}}(X_{f,n}, z)$. We could easily use a quasi-minimal modification of $\Gamma_{\text{can}}(X_{f,n})$, and the computation of the splice diagram would not change. Therefore, we can apply Theorem 2.4 to $\Gamma_{\text{can}}(X_{f,n})$.

Splice diagram in the general case. Assume we are not in the pathological case, and let $\Delta_{f,n}$ be the splice diagram associated to $\Gamma_{f,n} := \Gamma_{\text{can}}(X_{f,n})$. If a vertex $v$ in $\Gamma_{f,n}$ is in $q^{-1}(v_k)$ (respectively, $q^{-1}(\tilde{v}_k)$), we say that $v$ is “of type $v_k$” (respectively, $\tilde{v}_k$). We use the same terminology for the corresponding vertices of $\Delta_{f,n}$.

Consider a node $v$ of type $v_k$, $1 \leq k \leq s$, in $\Gamma_{f,n}$. In general, there are $h_k + \tilde{h}_k + 1$ edges adjacent to $v$: $h_k$ edges that lead to strings of (isomorphism) type $\Gamma(\overline{v}_k)$, $h_k$ edges that lead to subgraphs of type $\Gamma_-(v_k)$, and 1 edge that leads towards a subgraph of type $\Gamma_A(v_k)$. The corresponding pieces of $\Delta_{f,n}$ associated to the subgraphs of type $\Gamma_-(v_k)$ and $\Gamma_A(v_k)$ are denoted $\Delta_-(v_k)$ and $\Delta_A(v_k)$, respectively. Recall that $\Gamma_-(v_1) = \Gamma(\overline{v}_1)$, and $\Gamma_A(v_s) = \Gamma(v_s)$, and keep in mind that $\Gamma(v_s)$ may be empty.

The weights of the splice diagram $\Delta_{f,n}$ are given by Lemmas 3.3, 3.4, and 3.5. At a node of type $v_k$ in $\Delta_{f,n}$, the weights on the $h_k$ edges that lead to leaves of type $\overline{v}_k$ are $D_-(\overline{v}_k) = p_k$; the weights on the $h_k$ edges connected to subgraphs of type $\Delta_-(v_k)$ are $D_-(v_k)$; and the weight on the single edge connected to the subgraph of type $\Delta_A(v_k)$ is $D_A(v_k)$ (see Figure 4).

![Figure 4. Splice diagram at a node of type $v_k$, $2 \leq k \leq s - 1$.](image)

The pathological case. For this case $(n = p_s = 2)$, it is more convenient to use the splice diagram associated to the minimal resolution graph $\Gamma_{\text{min}}(X_{f,n})$ (see Figure 5). Here, $h_s = 2$, hence $n/h_s = n/d_{s-1} = 1$. Then, by definition $h_k = \tilde{h}_k = 1$ for $1 \leq k \leq s - 1$, and $\tilde{h}_s = 1$ since $\text{gcd}(p_s, a_s) = 1$. The link is a QHS, and the only string of type $\Gamma(\overline{v}_k)$ that collapses completely in $\Gamma_{\text{min}}(X_{f,n}, z)$ is $\Gamma(\overline{v}_s)$ (Proposition 3.8). The graph $\Gamma_{\text{min}}(X_{f,n})$ has a total of $2(s - 1)$ nodes: two of type $v_k$ for each $k$, $1 \leq k \leq s - 1$. Each of these nodes has valency three.

Since the determinant of a resolution tree remains constant throughout the minimalization process, the weights of the splice diagram associated to $\Gamma_{\text{min}}(X_{f,n})$ can be determined from Lemmas
3.3 and 3.5 Since \( h_k \tilde{h}_k = 1 \) for \( 1 \leq k \leq s - 1 \), we have \( D_-(v_k) = a_k \) for \( 2 \leq k \leq s \). Define integers \( \tilde{A}_k \) as follows:

\[
\tilde{A}_k := a_s - a_k p_k p_{k+1}^2 \cdots p_{s-1}^2, \quad \text{for} \ 1 \leq k \leq s - 2,
\]

\[
\tilde{A}_{s-1} := a_s - a_{s-1} p_{s-1}.
\]

It is easy to check that \( D_A(v_k) = \tilde{A}_k \) for \( 1 \leq k \leq s - 1 \).

![Figure 5. Splice diagram for the pathological case.](image)

4. The semigroup conditions

In this section, we discuss the semigroup conditions for the splice diagram \( \Delta_{f,n} \). Throughout this section, we assume that we are not in the pathological case. For a node \( v \) of type \( v_k \) in \( \Delta_{f,n} \), \( 1 \leq k \leq s \), there are at most two inequivalent semigroup conditions to check: one for an edge that leads to a subdiagram of type \( \Delta_-(v_k) \) (nontrivial for \( 2 \leq k \leq s \)), and one for the edge that leads to a subdiagram of type \( \Delta_A(v_k) \) (nontrivial for \( 1 \leq k \leq s - 1 \)). Clearly, for a fixed \( k \), the semigroup conditions are equivalent for any node \( v \) of type \( v_k \).

**Semigroup conditions in the direction of \( \Delta_-(v_k) \).**

**Lemma 4.1.** Let \( v \) be a node of type \( v_k \), \( 2 \leq k \leq s \), and let \( w_j \) be a leaf of type \( \overline{v}_j \) in \( \Delta_-(v) \), \( 0 \leq j \leq k - 1 \). Then

\[
\ell'_{w_j v} = \begin{cases} 
(D_-(v_k)/a'_k)p'_1 \cdots p'_{k-1} & \text{for } j = 0 \\
(D_-(v_k)/a'_k)a'_j p'_{j+1} \cdots p'_{k-1} & \text{for } 1 \leq j \leq k - 2 \\
(D_-(v_k)/a'_k) & \text{for } j = k - 1.
\end{cases}
\]

**Proof.** We prove this by induction on \( k \). For \( k = 2 \), the lemma is true, since if \( v \) is a node of type \( v_2 \),

\[
\ell'_{w_0 v} = (a'_1)h_1^{-1}(p'_1)^{h_1},
\]

\[
\ell'_{w_1 v} = (a'_1)h_1^{-1}(p'_1)^{h_1-1}, \quad \text{and}
\]

\[
D_-(v_2)/a'_2 = (a'_1)h_1^{-1}(p'_1)^{h_1-1}.
\]

Now assume the lemma is true for \( k = i - 1 \); we show that it is true for \( k = i \). Fix a node \( v \) of type \( v_i \), and (abusing notation), let \( v_{i-1} \) denote the unique node of type \( v_{i-1} \) in \( \Delta_-(v) \). For \( 0 \leq j \leq i - 2 \), any leaf of type \( \overline{v}_j \) in \( \Delta_-(v) \) is in one of the subdiagrams of type \( \Delta_-(v_{i-1}) \). Thus (refer to Figure 6)

\[
\ell'_{w_j v} = \begin{cases} 
D_-(v_{i-1})h_{i-1}^{-1}(p'_i)^{h_{i-1}^{-1}} & \text{for } 0 \leq j \leq i - 2 \\
D_-(v_{i-1})h_{i-1}(p'_i)^{h_{i-1}-1} & \text{for } j = i - 1.
\end{cases}
\]

![Figure 6. Relevant portion of \( \Delta_{f,n} \) at a node \( v \) of type \( v_i \).](image)

By Lemma 3.4 we have \( D_-(v_j)/a'_{i-1} = (p'_i)^{h_{i-1}^{-1}} \cdot D_-(v_{i-1})/a'_{i-1} \). Applying this fact and the induction hypothesis yields the desired result. \( \square \)
Proposition 4.2. At a node of type $v_k$, $2 \leq k \leq s$, the semigroup condition in the direction of any of the $h_k$ edges that lead to a subdiagram of type $\Delta_-(v_k)$ is equivalent to

$$a'_k \in \mathbb{N}(a'_{k-1}, p'_1 p'_2 \cdots p'_{k-1}, a'_j p'_{j+1} \cdots p'_{k-1}, 1 \leq j \leq k-2).$$

Furthermore, if $\widetilde{h}_k = 1$, this condition is automatically satisfied.

Proof. Fix a node $v$ of type $v_k$. By Definition 2.11 the condition is

$$D_-(v_k) \in \mathbb{N}(\ell'_{vw} \mid w \text{ is a leaf in } \Delta_-(v)).$$

The leaves in $\Delta_-(v)$ are of type $\overline{vw}$, for $j$ such that $0 \leq j \leq k-1$. Hence, there are $k$ generators for the semigroup in question, namely, $\ell'_{vw_j}$, $0 \leq j \leq k-1$, where $w_j$ denotes any leaf in $\Delta_-(v)$ of type $\overline{vw}$. The first statement of the Proposition follows from Lemmas 5.4 and 4.1 since $D_-(v_k)$ and all generators of the semigroup are divisible by $D_-(v_k)/a'_k$.

The second statement follows from [12], Proposition 8.1. $\Box$

Semigroup conditions in the direction of $\Delta_A(v_k)$. Fix an integer $k$, $1 \leq k \leq s-1$, and fix a node $v$ of type $v_k$. By definition, the semigroup condition is $D_A(v_k) \in R_k$, where

$$R_k := \mathbb{N}(\ell'_{vw} \mid w \text{ is a leaf in } \Delta_A(v)).$$

Refer to Figure 7 for what follows. There is at least one leaf $w_s$ in $\Delta_A(v)$ of type $\overline{vw}$ connected to $v_s$

(\text{the unique node of type $v_s$}, and if $n/h_s \widetilde{h}_s \neq 1$, there is a leaf $w_n$ resulting from the string $\Gamma(v_s)$ in $\Gamma_{f,n}$. These contribute $\ell'_{vw}$ and $\ell'_{vw_n}$ as generators of $R_k$.

Next, travel along the shortest path from $v$ to $v_s$. If $k < s-1$, this path contains one node of type $v_m$, for each $m$ such that $k+1 \leq m \leq s-1$. Since there can be no confusion here, we will simply refer to the nodes along this path as $v_m$. Each of these nodes is directly connected to at least one leaf $w_m$ of type $\overline{vw}$. Each such leaf contributes the generator $\ell'_{vw_m}$ to $R_k$. If $h_i = 1$ for $k+1 \leq i \leq s$, there are no other types of leaves in $\Delta_A(v)$, and we have listed all the generators of $R_k$.

For each $m$ such that $h_m \neq 1$, $k+1 \leq m \leq s$, there are more generators for $R_k$, namely $\ell'_{vw_m}$ for each type of leaf $w$ in $\Delta_-(v_m)$. There are $m$ such different types of leaves: type $\overline{vw}$, for $j$ such that $0 \leq j \leq m-1$. Let $w_j^m$ be a leaf of type $\overline{vw}$ in $\Delta_-(v_m)$. Then the generators of the semigroup $R_k$ are:

$$\begin{cases}
\ell'_{vw_m}, & k+1 \leq m \leq s, \\
\ell'_{vw_j^m}, & 0 \leq j \leq m-1, \text{for all } m \text{ such that } k+1 \leq m \leq s \text{ and } h_m \neq 1 \\
\ell'_{vw_n} & (\text{absent if } n/h_s \widetilde{h}_s = 1)
\end{cases}.$$
Proposition 4.3. Suppose $h_s > 1$. Then the semigroup conditions imply that $h_s = p_s$ and $h_{s-1}h_{s-1} = 1$.

Proof. Note that since the link is a QHS, $h_s > 1$ implies $\tilde{h}_s = 1$. Let $v$ be a node of type $v_{s-1}$, and consider the semigroup condition at $v$ in the direction of $\Delta_A(v)$: $D_A(v_{s-1})$ is in the semigroup $R_{s-1}$. The generators of $R_{s-1}$ are $\ell'_{vw}$, $\ell'_{vwj}$, $0 \leq j \leq s - 1$, and $\ell'_{wv}$ (absent if $n/h_s = 1$). It is easy to check (see Figure 8) that

$$
\ell'_{vw} = (n/h_s)D_-(v)h_{s-1}^{-1},
\ell'_{wv} = p_sD_-(v)h_{s-1}^{-1}, \text{ and}
\ell'_{vwj} = (n/h_s)p_sD_-(v)h_{s-2}^{-2}\ell'_{vwj}.
$$

By Lemma 4.3 since $d_{s-1} = h_s$ and $a'_s = a_s$,

$$
D_A(v_{s-1}) = \frac{nA_{s-1}D_-(v)h_{s-1}^{-1}}{h_{s-1}h_{s-1}h_s},
$$

where $A_{s-1} = a_s - 1p_s^{-1}p'_s + q_s = a_s - 1p_{s-1}(p_s - p'_s)$. Note that $n/(h_{s-1}h_{s-1}h_s)$ and $D_-(v)h_{s-1}^{-1}/a_s$ are both integers in this case. Since $p_s > p'_s = p_s/h_s$,

$$
\frac{n}{h_{s-1}h_{s-1}h_s} \left[a_s - a_{s-1}p_{s-1}(p_s - p'_s)\right] < \frac{n}{h_{s-1}h_{s-1}h_s}a_s \leq \frac{n}{h_s}a_s,
$$

and therefore $D_A(v_{s-1}) < \ell'_{vw}$. Hence we can forget about the generator $\ell'_{vw}$, since it is too large.

By Lemma 4.4

$$
\ell'_{vwj} = \begin{cases} 
    p'_1 \cdots p'_{s-1} : D_-(v)/a_s & \text{for } j = 0 \\
    a'_{s-1}p'_{s-1} \cdots p'_{s-1} : D_-(v)/a_s & \text{for } 1 \leq j \leq s - 2 \\
    a'_{s-1} : D_-(v)/a_s & \text{for } j = s - 1.
\end{cases}
$$

So, all generators of $R_{s-1}$ and $D_A(v_{s-1})$ are divisible by $D_-(v)h_{s-1}^{-1}/a_s$, and the semigroup condition is equivalent to the following:

$$
(3) \quad \frac{n}{h_s}p'_1 \cdots p'_s, \quad \frac{n}{h_s}a'_j p'_{j+1} \cdots p'_s : 1 \leq j \leq s - 1, \quad a_sp'_s \text{ (Absent if } \frac{n}{p_s} = 1).\]

All of the generators of this semigroup are divisible by $p'_s$. Therefore, the semigroup condition implies that $p'_s$ divides $n/(h_{s-1}h_{s-1}h_s)[a_s - a_{s-1}p_{s-1}(p_s - p'_s)]$. Suppose $p'_s > 1$. Since $p'_s$ divides $p_{s-1}$, and $(a_s, p_{s-1}) = 1$, this implies $p'_s$ divides $n/(h_{s-1}h_{s-1}h_s)$. This is impossible, since by definition $p'_s = p_s/(n, p_s)$, and thus $(p'_s, n) = 1$. Therefore we must have $p'_s = 1$. Since $p'_s = p_s/h_s$, we have shown that the semigroup conditions imply $h_s = p_s$.

Now we show that the semigroup conditions imply $h_{s-1}h_{s-1} = 1$. Note that if $n/h_s = 1$, this is automatically true by definition of $h_i$ and $h_s$. Therefore, assume that $n/h_s \neq 1$. Observe that all of the generators in (3) are divisible by $n/h_s$ except for $a_s$. Therefore, if the semigroup condition is satisfied, there exist $M$ and $N$ in $\mathbb{N} \cup \{0\}$ such that

$$
\frac{n}{h_{s-1}h_{s-1}}[a_s - a_{s-1}p_{s-1}(p_s - 1)] = Ma_s + Nn/h_s.
$$
Hence,
\[
\left( \frac{n}{(h_{s-1} \sim h_{s-1})} - M \right) a_s = \frac{Nn}{h_s} + \frac{n}{(h_{s-1} \sim h_{s-1})} a_{s-1} p_{s-1} (p_s - 1) \\
= \frac{n}{h_s} (N + a_{s-1} p_{s-1} (p_s - 1)).
\]
Since \((n, a_s) = 1\) by assumption, this implies that \(n/h_s \not\equiv 1\) divides \(\frac{n}{h_{s-1} \sim h_{s-1}} - M\). But we have
\[
0 < \frac{n}{h_{s-1} \sim h_{s-1}} - M \leq \frac{n}{h_{s-1} \sim h_{s-1}} \leq \frac{n}{h_s}.
\]
Therefore, the only possibility is \(n/h_s = n/(h_{s-1} \sim h_{s-1}) - M\), i.e., \(M = 0\) and \(h_{s-1} \sim h_{s-1} = 1\). □

**Lemma 4.4.** Assume \(s \geq 3\), and that \(h_{s-1} \sim h_{s-1} = 1\). Then the semigroup conditions imply that \(h_k \sim h_k = 1\) for \(1 \leq k \leq s - 2\).

**Proof.** We prove this by strong downward induction on \(k\). First we show that the semigroup conditions imply that \(h_{s-2} \sim h_{s-2} = 1\). By Proposition 3.2(a), there are \(h_s\) nodes of type \(v_{s-1};\) let \(v\) be any such node. We will show that the semigroup condition for \(v\) in the direction of \(\Delta A(v)\) cannot be satisfied if \(h_{s-2} \sim h_{s-2} \not\equiv 1\).

Let \(A_i = a_s - a_i p_i p_{i+1}^2 \cdots p_{s-2} (p_s - p_s')\), \(1 \leq i \leq s - 2\). By Lemma 3.5,
\[
D_A(v_{s-1}) = \begin{cases} 
\frac{n(p_s)^{h_{s-1}}}{n h_{s-1} D_-(v_s)^{h_{s-1}}} & \text{for } h_s = 1 \\
\frac{n h_{s-1} D_-(v_s)^{h_{s-1}}}{n h_{s-1} h_{s-1}} & \text{for } h_s > 1,
\end{cases}
\]
and
\[
D_A(v_{s-2}) = \begin{cases} 
\frac{n}{h_{s-1} h_{s-1}} (p_s)^{h_{s-1}} & \text{for } h_s = 1 \\
\frac{n h_{s-1} D_-(v_s)^{h_{s-1}}}{n h_{s-1} h_{s-1}} & \text{for } h_s > 1.
\end{cases}
\]
The generators of \(R_{s-2}\) are
\[
\left\{ \begin{array}{l}
el'_{v_{s-1}} = D_A(v_{s-1}), \\
el'_{v_{s-2}} = n/(h_s h_{s-1}) p_{s-1} D_-(v_s)^{h_{s-1}} p_{s-1}^{h_{s-1}}, \\
el'_{v_{s-2}^j} = n/(h_s h_{s-1}) p_{s-1} D_-(v_s)^{h_{s-2}} p_{s-1}^{h_{s-2}} p_{v_{s-2}^j}, 0 \leq j \leq s - 1,
\end{array} \right.
\]
although the \(\{e'_{v_{s-1}}\}^{s-1}_{j=0}\) are absent if \(h_s = 1\), and \(e'_{v_{s-2}}\) is absent if \(n/h_s h_{s-1}\).

We will consider two separate cases: (i) \(h_s = 1\), and (ii) \(h_s > 1\).

Case (i). If \(h_s = 1\), it is easy to see that if \(h_{s-2} h_{s-2} \not\equiv 1\), then \(e'_{v_{s-1}} > D_A(v_{s-2})\). Then, since \(D_A(v_{s-2})\) and every generator of the semigroup are divisible by \((p_s)^{h_{s-1}}\), the semigroup condition is equivalent to: \(n/(h_{s-2} h_{s-2})\) is in the semigroup generated by \(p_{s-1} n/h_s h_{s-1}\) and \(p_{s-1} p_s\) (absent if \(n/h_s = 1\)). Thus the semigroup condition implies that \(n/(h_{s-2} h_{s-2})\) is divisible by \(p_{s-1}\), which is impossible since \(h_{s-1} = (n, p_{s-1}) = 1\). Therefore, we must have \(h_{s-2} h_{s-2} = 1\). (Note that the argument is valid even if \(n/h_s = 1\) or \(h_s = 1\).

Case (ii). For \(h_s > 1\), the proof that \(h_{s-2} h_{s-2}\) must be 1 is nearly identical to the proof of Proposition 4.3, so we just give the outline here. Recall that the semigroup conditions imply that \(p_{s-1}' = 1\) in this case. Furthermore, we can assume that \(n/h_s \not\equiv 1\), since otherwise the Lemma is trivially true by definition of \(h_i\) and \(h_{i+1}\).

Dividing \(D_A(v_{s-2})\) and all the generators of \(R_{s-2}\) by \(D_-(v_s)^{h_{s-1}}/a_s\), we see that the semigroup condition for \(v\) in the direction of \(\Delta A(v)\) implies that \(n/(h_{s-2} h_{s-2}) A_{s-2}\) is in the semigroup generated by \(a_s p_{s-1}\) and a collection of positive integers that are divisible by \(n/h_s\). The semigroup condition implies that there exist \(M\) and \(N\) in \(\mathbb{N} \cup \{0\}\) such that
\[
n/(h_{s-2} h_{s-2}) A_{s-2} = M a_s p_{s-1} + N n/h_s.
\]
Just as in the proof of Proposition 4.3, we see that we must have \(M = 0\) and \(h_{s-2} h_{s-2} = 1\). Thus, we have taken care of both cases in the basis step.
For the inductive step, assume that $h_i h_i = 1$, for all $i$ such that $k + 1 \leq i \leq s - 1$. Now let $v$ be one of the $h_s$ nodes of type $v_k$. One can show that the semigroup condition for $v$ in the direction of $\Delta A(v)$ cannot be satisfied if $h_k h_k \neq 1$. In both cases $h_s = 1$ and $h_s > 1$, the proof is essentially the same as that of the basis step, so we omit the details.

Proposition 4.3 and Lemma 4.4 together imply the following

**Corollary 4.5.** Suppose $h_s > 1$. Then the semigroup conditions imply that $h_k h_k = 1$ for $1 \leq k \leq s - 1$.

In section 6 we will see that for the case $h_s = 1$, the semigroup conditions and congruence conditions together imply that $h_k h_k = 1$ for $1 \leq k \leq s - 1$.

5. Action of the discriminant group

In order to use Proposition 2.5 to check the congruence conditions for the resolution graph $\Gamma_{f,n}$, we must compute $c_w \cdot c_w$ for all leaves $w$. By Proposition 2.7 this amounts to computing the continued fraction expansions of the strings from leaves to nodes. This is essentially done in Mendris and Némethi's paper [4], proof of Prop. 3.5, but we need a bit more detail than they included.

5.1. Background. We begin with a summary of facts that we need, which can be found in [5]. Let $a$, $Q$, and $P$ be strictly positive integers with $\gcd(a, Q, P) = 1$. Let $(X(a, Q, P), 0)$ be the isolated surface singularity lying over the origin in the normalization of $\{(U^a V^Q = W^P), 0\}$. Let $\lambda$ be the unique integer such that $0 \leq \lambda < P/(a, P)$ and

$$Q + \lambda \cdot \frac{a}{(a, P)} = m \cdot \frac{P}{(a, P)}$$

for some positive integer $m$. If $\lambda \neq 0$, then let $k_1, \ldots, k_t \geq 2$ be the integers in the continued fraction expansion of $\frac{P/(a, P)}{Q/(a, P)}$.

The minimal embedded resolution graph of the germ induced by the coordinate function $V$ on $(X(a, Q, P), 0)$ is given by the string in Figure 9 (omitting the multiplicities of the vertices). If $\lambda = 0$,

$$(0) \leftarrow \bullet \quad \bullet \quad \ldots \quad \bullet \quad (1_{\frac{P}{(a, P)}})$$

**Figure 9.** The embedded resolution graph $\Gamma(X(a, Q, P), V)$.

the string is empty. One can similarly describe the embedded resolution graphs of the functions $U$ and $W$, but we do not need them here.

**Lemma 5.1.** Let $N$, $M$, $P$, and $Q$ be positive integers such that $(Q, P) = 1$ and $(N, M) = 1$. Let $\Gamma$ be the resolution graph of the singularity in the normalization of $\{(U^a V^Q = W^P), T^N = V^M, 0\} \subseteq (C^4, 0)$. Let $\lambda$ be the unique integer such that $0 \leq \lambda < P/(N, P)$ and

$$Q \cdot \frac{N}{(N, P)} + \lambda = m \cdot \frac{P}{(N, P)}$$

for some positive integer $m$. Then if $\lambda \neq 0$, $\Gamma$ is a string of vertices with continued fraction expansion $\frac{P/(N, P)}{Q/(N, P)}$.

**Proof.** We may assume $M = 1$, since it easy to check that the singularity in question has the same normalization as $\{U^a V^Q = W^P, T^N = V\} \subseteq C^4$. Therefore, $\Gamma$ is the resolution graph of the singularity in the normalization of $\{U^a V^Q = W^P\}$, which is the same as the resolution graph of

$$X \left(1, Q \cdot \frac{N}{(N, P)}, \frac{P}{(N, P)}\right) = \{U^a V^Q = W^P\}.$$

☐
5.2. Strings in $\Gamma_{f,n}$. We need the continued fraction expansion of the strings in $\Gamma_{f,n}$ from leaves of type $\overline{v_k}$, $0 \leq k \leq s$, to the corresponding node of type $v_k$ (from type $\overline{v_0}$ to type $v_1$). First we recall the construction of $\Gamma(\mathbb{C}^2, f)$, the minimal good embedded resolution graph of $f$ in $\mathbb{C}^2$, as in [4]. Let $f$ have Newton pairs $\{(p_k, q_k) \mid 1 \leq k \leq s\}$. Determine the continued fraction expansions

$$\frac{p_k}{q_k} = \mu_k^0 - \frac{1}{\mu_k^1 - \frac{1}{\mu_k^2 - \cdots - \frac{1}{\mu_k^s}}} \quad \text{and} \quad \frac{q_k}{p_k} = \nu_k^0 - \frac{1}{\nu_k^1 - \frac{1}{\nu_k^2 - \cdots - \frac{1}{\nu_k^s}}}$$

where $\mu_k^0, \nu_k^0 \geq 1$, and $\mu_k^j, \nu_k^j \geq 2$ for $j > 0$. Then $\Gamma(\mathbb{C}^2, f)$ has the schematic form given in Figure 2. The strings from $\overline{v_0}$ to $v_1$ and from $\overline{v_k}$ to $v_k$, $1 \leq k \leq s$, are given in Figure 10. The multiplicities of the vertices $v_k$ are $m_{v_k} = a_k p_k p_{k+1} \cdots p_s$, for $1 \leq k \leq s$.

$\overline{v_0}$: $- \mu_1^1 \frac{1}{- \mu_1^2 \frac{1}{- \mu_1^3 \frac{1}{\nu_1 \cdots v_1}}}$

$\overline{v_k}$: $- \nu_k^1 \frac{1}{- \nu_k^2 \frac{1}{- \nu_k^3 \frac{1}{\nu_k \cdots v_k}}}$

**Figure 10.** Strings in $\Gamma(\mathbb{C}^2, f)$.

Consider the string in Figure 11. The continued fraction expansion $[\nu_k^1, \ldots, \nu_k^s]$ corresponds to

$$\begin{array}{cccccccc}
(0) & \rightarrow & - \nu_k^1 & \rightarrow & - \nu_k^2 & \rightarrow & - \nu_k^s & \rightarrow (a_k p_k \cdots p_s).
\end{array}$$

**Figure 11.** String from $\Gamma(\mathbb{C}^2, f)$.

$p_k/\eta_k$, where $q_k + \eta_k = \nu_k^0 p_k$. Let $X := X(1, q_k, p_k)$. Then this string is the embedded resolution graph of $V^{a_k p_{k+1} \cdots p_s}$ in $X$. It follows from the construction of $\Gamma_{f,n}$ that the collection of strings that lies above this one in $\Gamma_{f,n}$ is the (possibly non-connected) resolution graph of the singularity in the normalization of $\{UV^{q_k} = W^{p_k}, T^n = V^{a_k p_{k+1} \cdots p_s}\}$. There are $(n, a_k p_{k+1} \cdots p_s) = h_k d_k = h_k h_{k+1} \cdots h_s$ connected components (see Definition 3.1), each being the resolution graph of the normalization of

$$\{UV^{q_k} = W^{p_k}, T^n/(h_k d_k) = V^{a_k' p_{k+1} \cdots p_s'}\}.$$

Now we are in the situation of Lemma 5.1 with $Q = q_k, P = p_k$, and $N = n/(h_k d_k)$. We have $(N, P) = (n/(h_k d_k), p_k) = h_k$ by definition of $h_k$, and so in this case $P/(N, P) = p_k'$ (as expected from Proposition 3.3). If $p_k' = 1$, then upon minimalization, the string of type $\overline{v_k}$ would completely collapse.

Suppose $p_k' \neq 1$. By Lemma 5.1, the continued fraction expansion of the string(s) from a leaf of type $\overline{v_k}$ to the corresponding node of type $v_k$ in the minimalization of the resolution graph $\Gamma_{f,n}$ is given by $p_k'/\eta_k'$, where $\eta_k'$ is the unique integer such that $0 < \eta_k' < p_k'$ and

$$q_k + \eta_k' = m p_k'$$

for some positive integer $m$. Since $a_k = q_k + a_k-1 p_k-1 p_k$, we have

$$\eta_k' = -a_k \cdot \frac{n}{h_k h_k d_k} \pmod{p_k'}.$$

Knowing the congruence class of $\eta_k'$ modulo $p_k'$ is enough for our purposes.

The continued fraction expansion from $\overline{v_0}$ to $v_1$ in $\Gamma(\mathbb{C}^2, f)$ is given by $q_1/\eta_0 = a_1/\eta_0$, where $p_1 + \eta_0 = \mu_1^0 a_1$. Using an argument analogous to the one above, we have that if $a_1' \neq 1$, the
Applying the congruence (4), we have
\[ \eta_0' \equiv -p_1 \cdot \frac{n}{h_1h_1d_1} \pmod{a_1'}. \]

Recall the notation defined in section [2] for \( r \in \mathbb{Q} \), \( [r] = \exp(2\pi ir) \), and for a leaf \( w \in \Gamma_{f,n} \), \( e_w \) denotes the image in the discriminant group of the dual basis element in \( \mathbb{E}^* \) corresponding to \( w \).

**Corollary 5.2.** Let \( w_k \) be any leaf of type \( \overline{w}_k \) in \( \Gamma_{f,n} \), \( 0 \leq k \leq s \), and assume that \( p_k' \neq 1 \) (assume \( a_1' \neq 1 \) for \( k = 0 \)). Then

\[
[e_{w_k} \cdot e_{w_k}] = \begin{cases} 
\left( \frac{(n/h_1h_1d_1)(p_1a_2 \cdots a_s - A_1p_1')} {a_1'a_2' \cdots a_s} \right) & \text{for } k = 0 \\
\left( \frac{(n/h_kh_kd_2)(a_ka_{k+1} \cdots a_s - A_ka_k')} {p'_ka_{k+1} \cdots a_s} \right) & \text{for } 1 \leq k \leq s-1 \\
\left( \frac{(n/h_kh_k)(a_s - a_1')} {p'_s} \right) & \text{for } k = s.
\end{cases}
\]

**Proof.** Proposition [2] says that for a leaf \( w \) connected by a string of vertices to a node \( v \),

\[ e_w \cdot e_w = -d_v/(a^2 \det(\Gamma)) - p/d, \]

where \( d_v \) is the product of weights at the node \( v \), and \( d/p \) is the fraction corresponding to the string from \( w \) to \( v \). Let \( d_{vk} \) be the product of the weights at any node of type \( v_k \), \( 1 \leq k \leq s \) (refer to Figure 4). Then \( d_{vk} = D_A(v_k)D_{-}(v_k)^{h_k}(p_k')^{\tilde{h}_k} \).

We need the following fact, which follows from Lemmas [3,3] and [3,6] For any \( k \) such that \( 1 \leq k \leq s \),

\[ \det(\Gamma_{f,n}) = \frac{D_{-}(v_k)} {a_k'} \prod_{j=k}^{s} (p_j')^{h_j-1} D_{-}(v_j)^{h_j-1}. \]

Now, for \( 1 \leq k \leq s-1 \),

\[
e_{w_k} \cdot e_{w_k} = -D_A(v_k)D_{-}(v_k)^h(p_k')^{\tilde{h}_k} - \frac{\eta_k'} {p'_k} \]

\[ = -\left( \frac{nA_k \prod_{j=k+1}^{s} (p_j')^{h_j-1} D_{-}(v_j)^{h_j-1}} {h_kh_kd_ka_{k+1} \cdots a_s} \right) D_{-}(v_k)^{h_k}(p_k')^{\tilde{h}_k} - \frac{\eta_k'} {p'_k} \]

\[ = \frac{n/h_kh_kd_ka_k'a_k'} {p'_ka_{k+1} \cdots a_s} - \frac{\eta_k'} {p'_k}. \]

Applying the congruence \([4]\), we have

\[ [e_{w_k} \cdot e_{w_k}] = \left( \frac{n/h_kh_kd_ka_k'a_k'} {p'_ka_{k+1} \cdots a_s} - \frac{n/h_kh_kd_ka_k'a_k'} {p'_ka_{k+1} \cdots a_s} \right), \]

and from here it is clear that the corollary is true. In the same way, it is easy to check that that \( [e_{w_0} \cdot e_{w_0}] \) and \( [e_{w_s} \cdot e_{w_s}] \) are as stated. \( \square \)

**6. PROOF OF THE MAIN THEOREM**

In this section, we prove the Main Theorem, which determines precisely which \((X_{f,n},0)\), with \( f \) irreducible, have a resolution graph \( \Gamma_{f,n} \) and associated splice diagram \( \Delta_{f,n} \) that satisfy both the semigroup and congruence conditions.

**Remark 6.1.**

1) The link is a ZHS if and only if \( n \) is relatively prime to all \( p_i \) and \( a_i \) (see [12]).

This is equivalent to all \( h_i \) and \( \tilde{h}_i \) being equal to 1. Hence this case belongs to (i) of the Main Theorem.

2) For the so-called pathological case \( n = p_s = 2 \), both semigroup and congruence conditions are satisfied only for \( s = 2 \).
3) There are classes of \((X_{f,n}, 0)\) for which the semigroup conditions are satisfied but the congruence conditions are not, but we do not write up a complete list of these types. An example with this property is given by \(n = 2, \ s = 2, \ p_1 = 2, \ a_1 = 3, \ p_2 = 3, \) and \(a_2 = 20.\) The minimal good resolution graph and splice diagram for this example are given in Figure 12.

![Figure 12](image-url)

**Figure 12.** Example for which the semigroup conditions are satisfied but the congruence conditions are not.

We must treat the cases \(h_s = 1\) and \(h_s > 1\) separately. The second case takes much more work than the first.

6.1. **Case (i) \(h_s = (n, p_s) = 1.\)** First of all, we have the following

**Proposition 6.2.** Suppose \(h_s = 1.\) If \(\Gamma_{f,n}\) satisfies the semigroup and congruence conditions, then \(h_i h_i = 1\) for \(1 \leq i \leq s - 1.\)

**Proof.** In light of Lemma 4.4, it suffices to show that the semigroup and congruence conditions imply \(h_{s-1} h_{s-1} = 1.\) We claim that the congruence condition at the unique node \(v\) of type \(v_{s-1}\) cannot be satisfied if \(h_{s-1} h_{s-1} \neq 1.\) Let \(u_j, 1 \leq j \leq h_s,\) denote the leaves of type \(\gamma_j\) in \(\Delta_{f,n},\) and let \(y\) denote the leaf that arises from the string \(\Gamma(v_s)\) in \(\Gamma_{can}(X_{f,n}, z),\) as in Figure 13. If \(n/h_s = 1,\) then the leaf \(y\) does not exist, but one can see that the argument holds regardless.

The semigroup condition at \(v\) in the direction of \(\Delta_A(v)\) says that there exist \(\beta\) and \(\alpha_i, 1 \leq i \leq h_s,\) in \(\mathbb{N} \cup \{0\}\) such that

\[
D_A(v_{s-1}) = \left( \sum_{i=1}^{h_s} \alpha_i \right) (p_s)^{h_{s-1}} n/h_s + \beta (p_s)^{h_s}.
\]

It follows from Lemma 3.3 that \(D_A(v_{s-1}) = n/(h_{s-1} h_{s-1}) (p_s)^{h_{s-1}}.\) Therefore, we have

\[
n/(h_{s-1} h_{s-1}) = \left( \sum_{i=1}^{h_s} \alpha_i \right) n/h_s + \beta p_s.
\]

If \(h_s = 1,\) it is clear that \(h_{s-1} h_{s-1} = 1\) must be 1; for, if not, \(\alpha_i\) must be zero, which would imply that \(p_s\) divides \(n/(h_{s-1} h_{s-1}).\) But this contradicts the assumption that \(h_s = 1.\) Furthermore, note that if all \(\alpha_i \geq 1,\) this implies that all \(\alpha_i\) must equal 1, \(\beta\) must be 0, and \(h_{s-1} h_{s-1} = 1.\) If we assume \(h_{s-1} h_{s-1} \neq 1,\) then there exists \(j\) such that \(\alpha_j = 0.\)
Let $U_j$ be the variable associated to the leaf $u_j$ (respectively, $Y$ associated to $y$). By Proposition 2.5 the congruence condition at $v$ in the direction of $\Delta_{A}(v)$ implies, in particular, that there exists an admissible monomial $H = U_1^{\gamma_1} \cdots U_{\overline{h}_{s}}^{\gamma_{\overline{h}_{s}}} Y^\beta$ such that for every leaf $u_j$, $1 \leq j \leq \overline{h}_{s}$,

$$\left[ \beta \frac{\ell_{y_{u_j}}}{\det(\Gamma_{f,n})} + \sum_{i \neq j} \alpha_i \frac{\ell_{u_i u_j}}{\det(\Gamma_{f,n})} - \alpha_j e_{u_j} \cdot e_{u_j} \right] = \left[ \frac{\ell_{v_{u_j}}}{\det(\Gamma_{f,n})} \right].$$

For the particular $j$ such that $\alpha_j = 0$, this condition is

$$\left( \beta \frac{\ell_{y_{u_j}}}{\det(\Gamma_{f,n})} + \sum_{i \neq j} \alpha_i \frac{\ell_{u_i u_j}}{\det(\Gamma_{f,n})} \right) = \left[ \frac{\ell_{v_{u_j}}}{\det(\Gamma_{f,n})} \right].$$

By Lemmas 3.4 and 3.6,

$$\det(\Gamma_{f,n}) = (p_s)^{\overline{h}_{s} - 1} \left( \frac{D_-(v_s)}{a'_s} \right) = (p_s)^{\overline{h}_{s} - 1} \left( \frac{D_-(v'_{s-1})}{a'_s} \right).$$

One can easily see that $[\frac{\ell_{v_{u_j}}}{\det(\Gamma_{f,n})}] = [0], [\frac{\ell_{y_{u_j}}}{\det(\Gamma_{f,n})}] = [0]$, and $[\frac{\ell_{u_i u_j}}{\det(\Gamma_{f,n})}] = [\frac{a'_s n/\overline{h}_{s}}{p_s}]$ for $i \neq j$. Thus the congruence condition (6) for the leaf $u_j$ is $\left( \sum_{i \neq j} \alpha_i \right) a'_s n/\overline{h}_{s} = [0]$; that is, $\left( \sum_{i \neq j} \alpha_i \right) a'_s n/\overline{h}_{s} \in \mathbb{Z}_{p_s}$. Since $a'_s$ and $n/\overline{h}_{s}$ are relatively prime to $p_s$, this implies that $\sum_{i \neq j} \alpha_i \in \mathbb{Z}_{p_s}$. But, by Equation (6), this implies that $n/(\overline{h}_{s-1}\overline{h}_{s-1})$ is divisible by $p_s$, which is a contradiction. Therefore, we must have $\overline{h}_{s-1}\overline{h}_{s-1} = 1$.

This leads us to the following

**Proposition 6.3.** Suppose $\overline{h}_{s} = 1$. Then $\Gamma_{f,n}$ satisfies the semigroup and congruence conditions if and only if both of the following hold:

(I) $\overline{h}_{i}\overline{h}_{i} = 1$ for $1 \leq i \leq s - 1$,

(II) $a'_s = \frac{a_s}{\overline{h}_{s}} \in \mathbb{N}(a_{s-1}, p_1 \cdots p_{s-1}, a_j p_{j+1} \cdots p_{s-1} : 1 \leq j \leq s - 2)$.

**Remark 6.4.** The condition (II) is clearly not always satisfied. For example, take $n$ divisible by $a_s$.

**Proof.** We have already shown (Propositions 6.2 and 12) that if the semigroup and congruence conditions are satisfied, then (I) and (II) must hold. So assume that (I) and (II) are satisfied. In the case that $\overline{h}_{s} = 1$, the link is a ZHS, and the semigroup conditions are satisfied 12. (There are no congruence conditions when the link is a ZHS.)

Assume $\overline{h}_{s} \neq 1$. By Lemma 3.4 $D_-(v_k) = a_k$, $2 \leq k \leq s - 1$, and $D_-(v_s) = a'_s$, and it follows from Lemma 5.5 that $D_A(v_k) = n(p_s)^{\overline{h}_{s} - 1}$, for $1 \leq k \leq s - 1$. There is exactly one node of type $v_k$ in $\Delta_{f,n}$ for $1 \leq k \leq s$, which we simply denote $v_k$. We denote the leaves $z_0, \ldots, z_{s-1}, u_1, \ldots, u_{\overline{h}_{s}}$, and $y$, as in Figure 14.

![Figure 14. Splice diagram for $\overline{h}_{s} \neq 1$ and $h_i h_i = 1$, $1 \leq i \leq s - 1$.](image-url)

It is clear from Proposition 4.2 that the semigroup condition at the node $v_k$ in the direction of $\Delta_-(v_k)$ is satisfied for $2 \leq k \leq s - 1$, and at the node $v_s$, this semigroup condition is equivalent to (II). Furthermore, one can see by examination of the splice diagram that the semigroup condition at each $v_k$ in the direction of $\Delta_A(v_k)$ is always satisfied (including in the case $n = \overline{h}_{s}$).
It remains to show that $\Delta_{f,n}$ satisfies the congruence conditions. Lemma 3.6 implies that $\det(\Gamma_{f,n}) = (p_s)\overline{h}_{s-1}$. In Figure 13, it is easy to see that for any node $v$ and any leaf $w$ in $\Delta_{f,n}$, $\ell_{vw}$ is always divisible by $(p_s)^{h_{s}-1}$. Therefore, $[\ell_{vw}/\det(\Gamma_{f,n})] = [0]$ for any node $v$ and any leaf $w$. For each node, there are at most two conditions to check: one for each adjacent edge that does not lead directly to a leaf. By Proposition 6.5, we must show that for every node $v$ and adjacent edge $e$, there is an admissible monomial $M_{ve} = \prod_{w \in \Delta_{ve}} z_{w,e}$ such that for every leaf $w'$ in $\Delta_{ve}$,

\[
\sum_{w \neq w'} \alpha_w \frac{\ell_{vw'}}{\det(\Gamma)} - \alpha_w c_{w'} c_{w'} = [0].
\]

In this case, we have $A_i = a_{i+1} \cdots a_s$ for $1 \leq i \leq s - 1$. Since $A_i p_i = a_2 \cdots a_s p_1$ and $A_j a_j = a_{j+1} \cdots a_s a_j$, Corollary 5.2 says that $[e_{z_j} e_{z_j}] = [0]$ for $0 \leq j \leq s - 1$. For any leaf $z_j$, $0 \leq j \leq s - 1$, it is easy to see that $\ell_{z_j w'}$ is divisible by $(p_s)^{h_{s}-1}$ for all leaves $w' \neq z_j$ in $\Delta_{f,n}$. Since the subgraph $\Delta_{-}(v_k)$ contains leaves only of the form $z_j$, $0 \leq j \leq k - 1$, Equation (7) holds for all leaves in $\Delta_{-}(v_k)$ for any choice of admissible monomial. (In fact, we have shown that the action of the discriminant group element $e_{z_j}$ is trivial for $0 \leq j \leq s - 1$.)

Let $Z_j$ be the variable associated to the leaf $z_j$, $0 \leq j \leq s - 1$. It is easy to check that for $1 \leq k \leq s - 2$, the congruence condition at $v_k$ in the direction of $\Delta_A(v_k)$ is satisfied for the admissible monomial $Z_{k+1}$. The only remaining condition is for the node $v_{s-1}$ in the direction of $v_s$. Let $U_j$ be the variable associated to the leaf $u_j$, $1 \leq j \leq \overline{h}_s$. We claim that the monomial $U_1 \cdots U_{\overline{h}_s}$ (which is easily seen to be an admissible monomial) satisfies the congruence condition. It is clear from the splice diagram that $[\ell_{u_j u_j}/\det(\Gamma_{f,n})] = [(n/\overline{h}_s) a_j' / p_s]$ for $i \neq j$, and by Corollary 5.2, since each $u_j$ is a leaf of type $\overline{v}_1$, $[e_{u_j} e_{u_j}] = [(n/\overline{h}_s)(a_s - a_s') / p_s]$ for all $j$. Hence, for each $u_j$, Equation (7) for the monomial $U_1 \cdots U_{\overline{h}_s}$ is

\[
[(\overline{h}_s - 1)(n/\overline{h}_s) a_s' / p_s - (n/\overline{h}_s)(a_s - a_s') / p_s] = [0].
\]

This is clearly true, since $\overline{h}_s a_s' = a_s$. Finally, for the leaf $y$, Equation (7) for $U_1 \cdots U_{\overline{h}_s}$ is

\[
[\ell_{yu_1} / \det(\Gamma_{f,n})] = [0]
\]

for any choice of $j$. Since $\ell_{yu_1}$ is divisible by $(p_s)^{h_{s}-1}$, the condition is satisfied. \hfill \Box

6.2. Case (ii) $h_s = (n, p_s) > 1$. The pathological case $n = p_s = 2$ is treated separately at the end of the section. The main goal of this section is to prove the following

**Proposition 6.5.** Suppose $h_s > 1$ and $n > 2$. Then $\Gamma_{f,n}$ satisfies the semigroup and congruence conditions if and only if

\[
(*) \quad s = 2, \quad p_2 = 2, \quad (n, p_2) = 2, \quad \text{and} \quad (n, a_2) = (n/2, p_1) = (n/2, a_1) = 1.
\]

Let us first assume that $\Gamma_{f,n}$ satisfies the semigroup and congruence conditions. We have already shown in (11) that the semigroup conditions imply $h_s = (n, p_s) = p_s$ and $h_i = 1$ for $1 \leq i \leq s - 1$. Recall that since the link is a QHS, $h_s = 1$ and $a_i' = a_i$. We prove that (*) must hold in two steps:

Step 1. The congruence conditions imply that $p_s = 2$.

Step 2. The congruence conditions imply that $s = 2$.

**Proof of Step 1.** For maximum convenience, we will use the splice diagram $\Delta$ associated to the minimal good resolution graph $\Gamma_{\min}(X_{f,n})$ (see Figure 14). Recall that $p_k' = 1$ implies that there is no leaf of type $\overline{v}_r$, since that string completely collapses in the minimal resolution graph. We show that the congruence condition as in Proposition 2.5 for a node $v$ of type $v_{s-1}$ in the direction of $\Delta_A(v)$ cannot hold unless $p_s = 2$. The only difficulty is in notation. By Lemmas 5.4 and 5.5, $D_{-}(v_k) = a_k$, for $2 \leq k \leq s$, and

\[
D_{A}(v_k) = \frac{n}{p_s} \tilde{A}_k(a_s)^{p_s - 2}, \quad \text{for} \quad 1 \leq k \leq s - 1,
\]

where $\tilde{A}_{s-1} = a_s - a_{s-1} p_{s-1} (p_s - 1)$, and $\tilde{A}_k = a_s - a_k' p_k p_{k+1} \cdots p_{s-1} (p_s - 1)$, $1 \leq k \leq s - 2$. Suppose that $p_s > 2$. For each $i$, $0 \leq i \leq s - 1$, there are $h_s = p_s$ leaves of type $\overline{v}_r$. We label
these leaves \( \{z_{1,j} \mid 1 \leq j \leq p_s\} \), as indicated in Figure 15. The leaf on the edge with weight \( n/p_s \) is denoted \( y \), and is absent if \( n/p_s = 1 \). Let the corresponding variables as in the Neumann-Wahl algorithm be \( \{Z_{i,j}\} \) and \( Y \), respectively. Let \( G \) be an admissible monomial for \( v \) in the direction of \( \Delta_A(v) \) (i.e., in the direction of the central node). We know that the variable \( Y \) cannot appear in any admissible monomial \( G \), by the proof of Proposition 4.3 \( \{M = 0\} \). Therefore, we have
\[
G = \prod_{j=2}^{p_s-1} (Z_{1,j})^{a_{1,j}} \cdots (Z_{s,j,k})^{a_{s,j,k}},
\]
with \( a_{j,k} \in \mathbb{N} \cup \{0\} \) such that
\[
D_A(v_{s-1}) = \sum_{k=0}^{s-1} \sum_{j=2}^{p_s} t_{v_{z_{j,k}}} a_{j,k}.
\]

For convenience of notation, we define integers \( M_i \) as follows:
\[
M_i := \begin{cases} 
1 \cdots p_{s-1} & \text{for } i = 0 \\
p_i p_{i+1} \cdots p_{s-1} & \text{for } 1 \leq i \leq s - 2 \\
1 & \text{for } i = s - 1.
\end{cases}
\]

(Note that \( M_i = \beta_i/p_s \)). Let \( v_s \) denote the unique node of type \( v_s \) (the central node). By Lemma 4.1, \( t_{v_{z_{j,k}}} = M_i \) for all \( j \). Therefore, \( t_{v_{z_{j,k}}} = M_i a_{s-1} p_a - 1(a_s)^{p_s-2} n/p_s \), and \( t_{v_{z_{j,k}}} = M_i a_{s-1} p_a - 1 \), for \( 1 \leq i \leq s - 1 \). Applying Equation (8) and cancelling \( (a_s)^{p_s-2} n/p_s \) from both sides of Equation (9) yields
\[
\hat{A}_{s-1} = \sum_{k=0}^{s-1} \sum_{j=2}^{p_s} M_k a_{j,k}.
\]

Consider the congruence condition in Proposition 2.5 for the node \( v \) in the direction of \( \Delta_A(v) \) for each of the leaves \( z_{2,j,k}, 0 \leq i \leq s - 1 \). By Lemma 5.6, \( \det(\Gamma_{j,n}) = (a_s)^{p_s-1} \). For any admissible monomial \( G \), the condition for \( w = z_{2,j,k} \) is equivalent to
\[
\left[ \sum_{k=0}^{s-1} \sum_{j=3}^{p_s} \alpha_{j,k} \frac{t_{z_{j,k}z_{2,i}}}{(a_s)^{p_s-1}} + \sum_{k \neq i} \alpha_{2,k} \frac{t_{z_{2,k}z_{2,i}}}{(a_s)^{p_s-1}} - \alpha_{2,i} e_{2,i} e_{z_{2,i}} \right] \left[ \frac{t_{z_{2,i}}}{(a_s)^{p_s-1}} \right] = 0.
\]

For \( 0 \leq i \leq s - 1 \),
\[
\frac{t_{z_{2,i}}}{(a_s)^{p_s-1}} = \frac{(n/p_s) M_i a_{s-1} p_a - 1}{a_s}.
\]

Furthermore, for any \( j \neq 2 \) and for \( 0 \leq k, i \leq s - 1 \),
\[
\frac{t_{z_{2,k}z_{2,i}}}{(a_s)^{p_s-1}} = \frac{(n/p_s) M_i M_k}{a_s}.
\]

Claim 6.6. Fix \( i \) such that \( 0 \leq i \leq s - 1 \). Then
\[
(a) \left[ e_{z_{2,i}} e_{z_{2,i}} \right] = \frac{(n/p_s) M_i^2 (p_s - 1)}{a_s}, \quad \text{and}
\]
\[
(b) \frac{t_{z_{2,k}z_{2,i}}}{(a_s)^{p_s-1}} = \frac{-(n/p_s) M_i M_k (p_s - 1)}{a_s}, \quad 0 \leq k \leq s - 1.
\]

Figure 15. Splice diagram for \( h_s = p_s \) and \( h_i h_i = 1 \) for \( 1 \leq i \leq s - 1 \).
Let us assume for now that Claim 6.6 is true and finish the proof of Step 1. By Equation (13) and the Claim, we have the following:

\[
\text{Left side of } (11) = \left[ \sum_{k=0}^{s-1} \sum_{j=k}^{s-1} \alpha_{j,k} \frac{M_i M_k}{a_s} - \sum_{k=0}^{s-1} \alpha_{2,k} \frac{M_i M_k (p_s - 1)}{a_s} \right]
\]

\[
= \left[ \frac{(n/p_s) M_i}{a_s} \left\{ \sum_{k=0}^{s-1} \alpha_{j,k} M_k - p_s \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right\} \right]
\]

\[
= \left[ \frac{(n/p_s) M_i}{a_s} \left\{ A_{s-1} - p_s \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right\} \right] \text{ (by (10))}
\]

\[
= \left[ \frac{(n/p_s) M_i}{a_s} \left\{ a_s - a_{s-1} p_s - (p_s - 1) - p_s \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right\} \right]
\]

\[
= \left[ \frac{(n/p_s) M_i}{a_s} \left\{ -a_{s-1} p_s - (p_s - 1) - p_s \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right\} \right].
\]

Therefore, by (13), the congruence condition (11) is equivalent to

\[
\left[ \frac{n/p_s}{a_s} M_i \left\{ a_{s-1} p_s - (p_s - 1) - p_s \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right\} \right] = \left[ \frac{n/p_s}{a_s} M_i a_{s-1} p_s - 1 \right],
\]

which is clearly equivalent to \[-(n/p_s) M_i p_s \left( a_{s-1} p_s - 1 + \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right) \right] = [0]. Since \((a_s, n) = 1\) and \((a_s, p_s) = 1\), this is equivalent to

\[
(14) \quad M_i \left( a_{s-1} p_s - 1 + \sum_{k=0}^{s-1} \alpha_{2,k} M_k \right) \in \mathbb{Z} a_s.
\]

Therefore, if the congruence conditions are satisfied, that implies, in particular, that (14) holds for all \(i\) such that \(0 \leq i \leq s - 1\).

We claim that if (14) holds for all \(i\), this implies that \(a_s\) divides

\[
S := a_{s-1} p_s - 1 + \sum_{k=0}^{s-1} \alpha_{2,k} M_k.
\]

Let \(a_s = q_s^{e_1} \cdots q_s^{e_1}\) be the prime power factorization of \(a_s\). Suppose there is some \(j\) such that \(q_s^{e_j}\) does not divide \(S\). Then at least one power of \(q_j\) must divide \(M_i\) for \(0 \leq i \leq s - 1\). In particular, \(q_j\) divides \(M_{s-1} = a_{s-1}\), and since \((a_{s-1}, p_{s-1}) = 1\), this implies that \(q_j\) divides \(a_{s-2}\), because \(M_{s-2} = a_{s-2} p_{s-1}\). This, in turn, implies \(q_j\) divides \(a_{s-3}\), and so forth, down to \(a_1\). But \(M_0 = p_1 \cdots p_{s-1}\), which cannot possibly be divisible by \(q_j\). We have a contradiction, and thus \(a_s\) divides \(S\).

Finally, we claim that for \(p_s > 2\), it is impossible for \(a_s\) to divide \(S\). Equation (13), which is equivalent to \(a_s - a_{s-1} p_s - (p_s - 1) = \sum_{k=0}^{s-1} \sum_{j=k}^{s-1} \alpha_{j,k} M_k\), implies that \(\sum_{k=0}^{s-1} \alpha_{2,k} M_k \leq a_s - a_{s-1} p_s - (p_s - 1)\), and hence

\[
S = a_{s-1} p_s - 1 + \sum_{k=0}^{s-1} \alpha_{2,k} M_k \leq a_s - a_{s-1} p_s - (p_s - 2).
\]

If \(p_s > 2\), \(a_s - a_{s-1} p_s - (p_s - 2) < a_s\), which implies that \(S < a_s\), and hence \(S\) cannot be divisible by \(a_s\), which is a contradiction. Therefore, we must have \(p_s = 2\) for the congruence conditions to be satisfied.

**Proof of Claim 6.6** Since \(z_{2,i}\) is a leaf of type \(\overline{a_i}\), (a) follows from Corollary 5.2. For (b), without loss of generality, we can assume \(i < k\). For \(1 \leq i < k \leq s - 2\), \(i \neq k - 1\), we have \(\ell_{z_{2,k}z_{2,i}} = \)
\[ D_A(v_k) a_i p_{i+1} \cdots p_{k-1}, \text{ and hence,} \]
\[
\frac{\ell_{z_2,kz_2,1}}{\text{det}(\Gamma_{f,n})} = \left[ \frac{(n/p_s) \tilde{A} k a_i p_{i+1} \cdots p_{k-1}}{a_s} \right] = \left[ \frac{(n/p_s)(a_s - a_kp_kp_k^{-1} \cdots p_{s-1}^2(p_s - 1)a_s p_{i+1} \cdots p_{k-1})}{a_s} \right] = \left[ \frac{-(n/p_s)(p_s - 1)a_kp_kp_k^{-1} \cdots p_{s-1}^2 a_s p_{i+1} \cdots p_{k-1}}{a_s} \right] = \left[ \frac{-(n/p_s)(p_s - 1)M_k M_{k+1}}{a_s} \right].
\]

The remaining cases are all similar and easy to check.

\[ \square \]

**Proof of Step 2.** So far, we have that the semigroup and congruence conditions imply that \( h_s = p_s = 2 \) and \( h_ih_i = 1 \) for \( 1 \leq i \leq s - 1 \). Write \( n = 2n' \) with \( n' > 1 \). We will show that for \( s \geq 3 \), the congruence conditions at a node \( v \) of type \( v_{s-2} \) in the direction of \( \Delta_A(v) \) cannot be satisfied. We should note that the congruence condition at a node of type \( v_{s-1} \) that we studied in Step 1 can be satisfied for \( s \geq 3 \). For example, take
\[
a_1 = 3, \quad a_2 = 19, \quad a_3 = 117, \quad p_1 = 2, \quad p_2 = 3, \quad p_3 = 2,
\]
and any \( n = 2n' \) such that \( n' \) is relatively prime to \( 2, 3, 13, \) and \( 19 \).

Figure 16 depicts the splice diagram in the general situation. The semigroup condition at \( v \) in

\[ \Delta_A(v_{s-2}) \]

the direction of \( \Delta_A(v) \) is
\[ D_A(v_{s-2}) \in \mathbb{N}(D_A(v_{s-1}), a_s p_{s-1}, n'p_{s-1} M_i, 0 < i < s - 1). \]

Recall that \( D_A(v_{s-1}) = n'(a_s - a_{s-1} p_{s-1}) \), and \( D_A(v_{s-2}) = n'(a_s - a_{s-2} p_{s-2} p_{s-1}^2) \). The semigroup condition implies that there exist \( \alpha, \beta, \gamma_i \in \mathbb{N} \cup \{0\} \) such that
\[
n'(a_s - a_{s-2} p_{s-2} p_{s-1}^2) = \alpha n'(a_s - a_{s-1} p_{s-1}) + \beta a_s p_{s-1} + \sum_{i=0}^{s-1} \gamma_i n' M_i p_{s-1}.
\]

If \( \beta \neq 0 \), then \( \beta a_s p_{s-1} \) must be divisible by \( n' > 1 \). By assumption, \( (a_s, n') = h_s = 1 \), and \( (p_{s-1}, n') = h_{s-1} = 1 \), and hence \( n' \) must divide \( \beta \). But then \( \beta a_s p_{s-1} \geq n'a_s p_{s-1} > n'a_s > D_A(v_{s-2}) \), and this is impossible. Therefore, \( \beta = 0 \).

Hence, we can cancel \( n' \) from the equation above, leaving
\[ a_s - a_{s-2} p_{s-2} p_{s-1}^2 = \alpha (a_s - a_{s-1} p_{s-1}) + \sum_{i=0}^{s-1} \gamma_i M_i p_{s-1}. \]

Since \( M_{s-1} = a_{s-1} \), we have
\[ (\alpha - \gamma_{s-1}) a_{s-1} p_{s-1} = (\alpha - 1) a_s + \sum_{i=0}^{s-2} \gamma_i M_i p_{s-1} + a_{s-2} p_{s-2} p_{s-1}^2, \]
which implies \( (\alpha - \gamma_{s-1}) a_{s-1} p_{s-1} > (\alpha - 1) a_s \). Suppose \( \alpha > 1 \). Then, since \( a_s = q_s + a_{s-1} p_{s-1} p_s \) and \( p_s = 2 \),
\[ (\alpha - \gamma_{s-1}) a_{s-1} p_{s-1} > (\alpha - 1) a_s > (\alpha - 1) 2 a_{s-1} p_{s-1}. \]
This implies \((\alpha - \gamma_{s-1}) - 2(\alpha - 1) > 0\), i.e., \(2 > \alpha + \gamma_{s-1}\). But this is impossible for \(\alpha > 1\).

Now suppose \(\alpha = 1\). It is clear from Equation (13) that \(\gamma_{s-1}\) must be 0, and so we have
\[
a_{s-1}p_{s-1} = \sum_{i=0}^{s-2} \gamma_i M_i p_{s-1} + a_{s-2} p_{s-2} p_{s-1}^2,
\]
i.e., \(a_{s-1} = \sum_{i=0}^{s-2} \gamma_i M_i + a_{s-2} p_{s-2} p_{s-1}\). But \(M_i\) is divisible by \(p_{s-1}\) for \(0 \leq i \leq s - 2\), so this would imply \(a_{s-1}\) is divisible by \(p_{s-1}\), which is impossible. Therefore, \(\alpha = 0\), and we have
\[
(16) \quad a_s - a_{s-2}p_{s-2}p_{s-1}^2 = \sum_{i=0}^{s-1} \gamma_i M_i p_{s-1}.
\]
(Note that this semigroup condition is already quite restrictive, because it requires \(a_s\) to be divisible by \(p_{s-1}\).

Now let us return to the congruence conditions for the node \(v\) in the direction of \(\Delta_A(v)\). An admissible monomial for \(v\) in that direction must be of the form \(H = Y_0^{s_0} \cdots Y_{s_{s-1}}^{s_{s-1}}\), with \(\gamma_i \in \mathbb{N}_0\).

The congruence condition for the leaf \(y_{s-1}\) is
\[
\left[ \frac{\ell v_{y_{s-1}}}{\det(\Gamma_{f,n})} \right] = \left[ \sum_{i=0}^{s-2} \gamma_i \frac{\ell v_{y_{i-1}y_i}}{\det(\Gamma_{f,n})} - \gamma_{s-1} e_{y_{s-1}} \cdot e_{y_{s-1}} \right].
\]
Applying Claim 6.6, this condition is equivalent to
\[
\left[ \frac{n' a_{s-2}p_{s-2}a_{s-1}p_{s-1}}{a_s} \right] = \left[ -\frac{n' a_{s-1}}{a_s} \left( \sum_{i=0}^{s-1} \gamma_i M_i \right) \right];
\]
that is, \(n' a_{s-1} \left( a_{s-2}p_{s-2}p_{s-1} + \sum_{i=0}^{s-1} \gamma_i M_i \right) \in \mathbb{Z}a_s\). Since \((a_s, n') = 1\), we must have
\[
a_{s-1} \left( a_{s-2}p_{s-2}p_{s-1} + \sum_{i=0}^{s-1} \gamma_i M_i \right) = Na_s\text{ for some }N \in \mathbb{Z}.\]
If we multiply both sides of this equation by \(p_{s-1}\) and apply Equation (16), we get
\[
a_{s-1} a_{s-2} p_{s-2} p_{s-1}^2 + a_{s-1} (a_s - a_{s-2} p_{s-2} p_{s-1}^2) = Na_s p_{s-1};
\]
i.e., \(a_{s-1} = N p_{s-1}\). This implies \(p_{s-1}\) divides \(a_{s-1}\), which is a contradiction.

Therefore, we have shown that if \(s \geq 3\), then the congruence condition for the node \(v\) of type \(v_{s-2}\) in the direction of \(\Delta_A(v)\) cannot be satisfied for the leaf \(y_{s-1}\). Hence, the congruence conditions imply that \(s = 2\).

We have finished Steps 1 and 2, hence have proved one direction of Proposition 6.5.

For the other direction, we must check that \((\ast)\) implies that the semigroup and congruence conditions are satisfied. The splice diagram in this situation is shown in Figure 17. The only

![Splice diagram for (\ast), \(n > 2\).](image)

semigroup condition that needs to be checked is
\[
D_A(v_1) \in \mathbb{N}(a_2, n'a_1, n'p_1),
\]
where \(D_A(v_1) = n'(a_2 - a_1p_1) = n'(q_2 + a_1p_1)\). Since \(a_1\) and \(p_1\) are relatively prime, the conductor of the semigroup generated by \(a_1\) and \(p_1\) is less than \(a_1p_1\), hence \(a_1p_1 + q_2\) is in the semigroup generated by \(a_1\) and \(p_1\), and therefore this semigroup condition is satisfied.

There are only two congruence conditions to check. One is equivalent to the following: there exist \(\alpha_0\) and \(\alpha_1\) in \(\mathbb{N} \cup \{0\}\) such that \(a_2 = \alpha_0 p_1 + \alpha_1 a_1\),
\[
\left[ \frac{\alpha_1 - n'a_1 p_1}{a_2} - \frac{n'a_1^2}{a_2} \right] = [0], \text{ and } \left[ \frac{\alpha_0 - n'a_1 p_1}{a_2} - \frac{n'a_1^2}{a_2} \right] = [0].
\]
But these conditions are obviously both satisfied for any \( \alpha_0, \alpha_1 \) such that \( a_2 = \alpha_0 p_1 + \alpha_1 a_1 \). The other congruence condition is equivalent to the following: there exist \( \gamma_0 \) and \( \gamma_1 \) in \( \mathbb{N} \cup \{0\} \) such that 

\[
\frac{1}{a_2} \left[ -n' a_1 p_1 - \frac{n' a_2^2}{a_2} \right] = \frac{1}{a_2} \left[ n' a_1^2 p_1 \right], \quad \text{and} \quad \frac{1}{a_2} \left[ -n' a_1 p_1 - \gamma_1 n' a_2^2 \right] = \frac{1}{a_2} \left[ n' a_1^2 p_1 \right].
\]

But these conditions are also obviously both satisfied for any \( \gamma_0, \gamma_1 \) such that \( a_2 - a_1 p_1 = \gamma_0 p_1 + \gamma_1 a_1 \). This concludes the proof of Proposition 6.5.

The pathological case. If \( h_s > 1 \) and \( n = 2 \), then the semigroup conditions imply that \( p_s = 2 \) by Proposition 1.3. Therefore, all that remains in the proof of the Main Theorem is the pathological case. Let \( \Gamma_{f,n} \) be the graph associated to the minimal good resolution (see §3).

**Proposition 6.7.** Suppose \( n = p_s = 2 \). Then \( \Gamma_{f,n} \) satisfies the semigroup and congruence conditions if and only if \( s = 2 \).

**Proof.** We begin by assuming that \( \Gamma_{f,n} \) satisfies the semigroup and congruence conditions. It is automatically true that \( h_i h_1 = 1 \) for \( 1 \leq i \leq s - 1 \), and that \( h_s = 2 \). We must show that \( s \) must be 2. The splice diagram is pictured in Figure 18.

![Splice diagram for the pathological case, s > 2.](image)

Step 2 above to show that for \( s > 3 \), the congruence conditions at the node \( v \) of type \( v_{s-2} \) in the direction of \( \Delta_A(v) \) cannot possibly be satisfied for the leaf \( y_{s-1} \).

The semigroup condition at \( v \) in the direction of \( \Delta_A(v) \) is 

\[ \bar{A}_{s-2} \in \mathbb{N}(A_{s-1}, p_{s-1} M_i, 0 \leq i \leq s - 1) \]

Precisely the same argument as in Step 2 above shows that \( \bar{A}_{s-1} \) cannot appear in the expression for \( A_{s-2} \) that comes from the semigroup condition. Therefore, there exist \( \gamma_i \) in \( \mathbb{N} \cup \{0\} \) such that 

\[
a_s - a_{s-2} - 2 p_{s-2}^2 \gamma_{s-1} = \sum_{i=0}^{s-1} \gamma_i M_i p_{s-1}.
\]

Let \( H = Y_0^{\gamma_0} \cdots Y_{s-1}^{\gamma_{s-1}} \) be an admissible monomial for \( v \) in the direction of \( \Delta_A(v) \). The congruence condition for the leaf \( y_{s-1} \) is equivalent to 

\[
\left[ \frac{a_{s-2} p_{s-2} a_{s-1} p_{s-1}}{a_s} \right] = \left[ -\frac{a_{s-1}}{a_s} \left( \sum_{i=0}^{s-1} \gamma_i M_i \right) \right].
\]

Just as in Step 2, this implies \( p_{s-1} \) divides \( a_{s-1} \), and hence the congruence conditions cannot be satisfied for \( s > 2 \).

Finally, for \( s = 2 \), it is easy to check that the semigroup and congruence conditions are satisfied.

\[ \square \]
