Background and purpose — Despite increased attention to and acceptance of fast-track procedures, there is a lack of studies concerning discharge on the day of surgery (DOS) following total knee arthroplasty (SD-TKA). We evaluated the feasibility of SD-TKA, and compared safety and patient-reported outcomes (PROs) between patients undergoing SD-TKA and patients undergoing standard TKA.

Patients and methods — A SD-TKA group (n = 101) was matched 1:1 to a standard TKA group (n = 101) on age, sex, and ASA score. Feasibility (being discharged on DOS), safety (unplanned contacts and complications evaluated by telephone calls (2 weeks), outpatient visits (2 weeks), and readmission (90 days)) were assessed. Further, Oxford Knee Score (OKS) and Visual Analogue Scale (VAS) (pain at rest and activity) were reported (90 days).

Results — 89 of 101 SD-TKA patients were discharged on DOS. The number of telephone calls (≤ 83) and outpatient visits (12) were similar in the 2 groups. The number of readmissions was ≤ 3 in both groups, and only 1 of the readmissions was related to TKA surgery. No differences were found at 90-day follow-up in terms of OKS (34 in both groups) or VAS (rest: SD-TKA = 7 and standard TKA = 8; activity: SD-TKA = 17 and standard TKA = 15).

Interpretation — SD-TKA is feasible in a selected group of patients, and safety and PROs are comparable to patients undergoing standard TKA.

As a result of general quality improvements in the clinical pathway of arthroplasty surgery, fast-track procedures have emerged, resulting in reduced mean length of stay (LOS) in hospital (1-5). In Denmark, mean LOS is 1.5 days for patients undergoing primary total knee arthroplasty (TKA) surgery (6). Recently, discharge on the same day as TKA surgery (SD-TKA) has increasingly gained attention and acceptance (5,7).

Several systematic reviews including studies on different arthroplasty procedures have revealed that discharge on the day of surgery appears feasible, safe, and effective in selected patients (1-4,8). The reviews on TKA include both comparative (non-randomized) and non-comparative studies; the definition of discharge on the day of surgery (DOS) varies, and clinical pathway protocols differ (1-4,8). Most studies were conducted in the United States, and only a few in Europe (9-13). Given the low number of patients undergoing SD-TKA in previous European studies, further studies on SD-TKA are warranted, particularly in Scandinavian populations. Furthermore, although the importance of patient-reported outcomes (PROs) is acknowledged when assessing knee function (5), only a few studies have reported PROs following SD-TKA (3,13).

This study evaluates the feasibility of SD-TKA, and compares safety and also PROs at 90-day follow-up between patients undergoing SD-TKA and patients undergoing standard TKA.
Patients and methods

This single-center cohort study, reported according to the STROBE Statement, compared a group of patients who underwent SD-TKA with a group of patients who underwent standard TKA. SD-TKA patients were scheduled to be discharged to their home on DOS, whereas standard TKA patients stayed at least 1 night in the hospital.

Patients were included from the Silkeborg Knee Replacement Study (SIKS) database. The SIKS database is a prospective cohort including 1,026 consecutive patients who underwent TKA at the Elective Surgery Center, Silkeborg Regional Hospital, Denmark (a public tax-financed hospital with free access for patients) between February 2018 and March 2020. From November 2018, the SIKS database also included SD-TKA patients; the first 18 patients were defined as pilot patients and treated in accordance with the clinical pathway protocol (Table 1, see Supplementary data). To imitate discharge to the home, pilot patients spent 1 night at the patient hotel accompanied by their own adult support person and without nightly nurse supervision. In the clinical setting, patients were scheduled to SD-TKA based on the following eligibility criteria: (i) primary unilateral TKA, (ii) accepting SD-TKA, (iii) ≥ 18 years, (iv) ASA score 1+2, (v) availability of an adult support person at home during the first 24 hours after discharge, (vi) living within 1-hour drive from the hospital, and (vii) not categorized as a pain care patient (pain care patients fulfill the following criteria: (a) intake of > 80 mg opioids/24 hours, (b) current or previous abuse of opioids or alcohol, (c) opioid intolerance, (d) previous gastric banding or sleeve operation, (e) current use of medicinal cannabis, (f) complex history of pain, and/or (g) current methadone treatment). All patients who were offered SD-TKA were consecutively included in the study from the SIKS database. For the purpose of the study and to ensure that the standard TKA group was as comparable as possible to the SD-TKA group we used the following selection criteria for the standard TKA group: (i) primary unilateral TKA, (ii) ≥ 18 years, (iii) ASA score 1+2, (iv) cohabiting (a proxy for criteria v) in the SD-TKA group, and (v) not categorized as a pain care patient.

Patients from the standard TKA group either underwent surgery before SD-TKA was initiated or in the same period as SD-TKA was offered. No procedural changes in the clinical pathway protocol occurred during the inclusion period. This justified the inclusion of standard TKA patients from the period prior to when SD-TKA was offered. SD-TKA patients were matched 1:1 on sex and age (nearest-neighbor in the interval between ± 5 years) with standard TKA patients. Of note are 2 issues. First, 4 of the pilot patients were discharged on the DOS. 1 of these 4 pilot patients was excluded due to being categorized as a pain care patient; thus, 3 pilot patients were included in the analyses as they were considered to have the same safety risk as the rest of the SD-TKA group. Second, 8 patients had been included as SD-TKA patients although they had an ASA score = 3, which was a predefined exclusion criterion in the clinical setting. As we intended the study to reflect clinical practice, it was decided to match these 8 patients with 8 patients with ASA score = 3 from the standard TKA group and include them in the analyses.

The clinical pathway was delivered by a multidisciplinary team consisting of anesthesiologists, orthopedic surgeons, nurses, and physiotherapists. The main differences in the clinical pathway of the 2 patient groups were: (i) that patients from the SD-TKA group were transferred to the day care unit whereas patients from the standard TKA group were transferred to a specialized orthopedic ward, and (ii) physiotherapy was initiated on DOS for the SD-TKA group, and the day after surgery for the standard TKA group (Table 1, see Supplementary data).

Participant and surgical characteristics were collected at baseline. Variables related to feasibility were LOS, and reason(s) for not being discharged on DOS. These variables were retrieved from the electronic medical record, and were collected retrospectively. In terms of safety, data on unplanned contacts and complications (i.e., the reason(s) for the unplanned contact) were collected and categorized into (i) telephone calls, (ii) outpatient visits, and (iii) readmission (admission to hospital for more than 12 hours). Data on telephone calls and outpatient visits was collected retrospectively from the electronic medical record within 2 weeks from discharge. Data on readmission was obtained retrospectively from the Danish National Patient Registry (DNPR) within the first 90 days after surgery. PROs on function and pain were measured by the Oxford Knee Score (OKS), a 12-item questionnaire summarized to a total score between 0 and 48 (the higher the score, the better function and pain) (14). PROs were also collected on mean pain intensity (rest and activity) during the last 24 hours by visual analogue scale (VAS) ranging from “no pain” (0) to “worst pain” (100) (15). PROs were collected prospectively at baseline and 90 days after discharge. In addition, data on activity level measured by the University of California at Los Angeles (UCLA) activity level scale (16), and data on health-related quality of life (HRQoL) measured by the EuroQol 5-domain 5-level (EQ-5D-5L) and EuroQol VAS (EQ VAS) (17) were collected at baseline.

Statistics

Participant and surgical characteristics plus PROs were presented with mean (SD) if normally distributed and median (IQR) if non-normally distributed. Categorical variables were reported as numbers and proportions.

LOS for each group and the reason(s) for not being discharged on DOS for the SD-TKA group were presented descriptively. Due to the inclusion of the 3 pilot patients a sensitivity analysis was performed in terms of feasibility. A descriptive comparison was made between groups in terms of unplanned contacts and complications. Student’s t-test was
by the Danish Health Data Board. Restrictions apply to the availability, as the data was used under license for the current study, and so is not publicly available.

The study was funded by grants from Fogs Fond; it played no role in the completion of the study or the manuscript. STS is funded by a grant from Region Zealand (Exercise First) and 2 grants from the European Union’s Horizon 2020 research and innovation program (MOBILIZE (No 801790) and ESCAPE (No 945377). All authors declared they had no conflicts of interest.

Results

Following the study inclusion and exclusion criteria and the matching procedure, each group consisted of 101 patients (Figure and Table 2).

In terms of feasibility, 89 of the 101 patients (88%) offered the SD-TKA procedure were discharged on DOS (Table 3).

By using data from the electronic medical record and the DNPR, we were able to obtain complete data on follow-up on unplanned contacts and complications (Figure). The number of telephone calls was similar in the 2 groups (Table 4). The main reasons for telephone calls were wound seepage/bleeding (SD-TKA), and pain management (standard TKA) (Table 5, see Supplementary data). The number of outpatient visits was identical in the 2 groups (Table 4). The main reasons for the outpatient visits were wound seepage/bleeding (SD-TKA) or related to swelling/compression stocking use (standard TKA) (Table 5, see Supplementary data). 3 patients were readmitted (admission to hospital for more than 12 hours) within the first 90 days after discharge. 2 of those patients were from the standard TKA group; 1 of them was readmitted once (tachycardia), and 1 was readmitted twice (cystitis and inpatient rehabilitation due to overweight). The 3rd patient was from the SD-TKA group and was readmitted for manipulation of the knee under anesthesia. The readmissions occurred between postoperative days 29 and 90, and are considered independent of TKA procedure (Table 4 and Table 5, see Supplementary data).

The 90-day follow-up rate for PROs was 87%. Patients in the 2 groups were similar with respect to mean OKS at baseline, 90-day follow-up, and when estimating the mean within- and between-group differences. A difference in median VAS (rest and activity) between the 2 groups was identified at baseline, but there was no statistically significant difference between the 2 groups either at baseline or at 90-day follow-up (Table 6).

We performed 3 secondary analyses. First, in the SD-TKA group, patients not discharged on DOS (n = 12) did not differ from those discharged on DOS (n = 89). Second, when comparing those discharged on DOS (n = 89) and their matched standard TKA patients (n = 89), unplanned contacts and PROs were similar to those from the primary analysis (including n

**Participant flow.** UKA: unicompartimental knee arthroplasty; TKA: total knee arthroplasty; SD-TKA: discharge on the same day as TKA surgery; Pain care: patients fulfilling the following criteria: (a) intake of > 80 mg opioids/24 hours, (b) current or previous abuse of opioids or alcohol, (c) opioid intolerance, (d) previous gastric banding or sleeve operation, (e) current use of medicinal cannabis, (f) complex history of pain, and/or (g) current methadone treatment; OKS: Oxford Knee Score.

**Ethics, registration, data sharing, funding, and potential conflicts of interest**

The SIKS database was approved by the Danish Data Protection Agency (1-16-02-935-17), and pre-registered at ClinicalTrials.gov (NCT03411083). Participants gave written informed consent. Central Denmark Region and the hospital management consented to transfer data from the electronic medical record to the SIKS database (1-45-70-70-20) after expiration of informed consent. The Danish Health Data Board provided data from the DNPR (00005469). Data on feasibility, telephone calls, outpatient visits, and PROs from the SIKS database is available from the authors upon reasonable request and with the needed permissions. Data on readmission from the Danish National Patient Registry was provided used to compare continuous parametric variables (OKS), and the Wilcoxon rank sum test was used to present non-normally distributed variables (VAS). We calculated 95% confidence intervals (CI) for within- and between-group differences on OKS and VAS. STATA 16 (V.16 Stata, College Station, TX, USA) was used for data analysis.

The SIKS database was funded by a grant from Region Zealand (Exercise First) and 2 grants from the European Union’s Horizon 2020 research and innovation program (MOBILIZE (No 801790) and ESCAPE (No 945377). All authors declared they had no conflicts of interest.
Third, a comparison of non-responders and responders to the 90-day PROs showed statistically significant differences in sex, ASA score, and VAS; no statistically significant differences in patient age and OKS were found (Tables 7 and 8, see Supplementary data).

### Discussion

This cohort study showed that the SD-TKA procedure was feasible, as 88% of the scheduled SD-TKA patients were discharged on DOS. Further, we found similar numbers of unplanned contacts and complications as well as similar PROs at 90-day follow-up when comparing the SD-TKA group with the standard TKA group, indicating that the SD-TKA procedure is safe in a selected group of patients.

a from discharge until the follow-up visit 2 weeks postoperatively.  
b admission to hospital for more than 12 hours within the first 90 days after surgery.
A single study and a review including 6 studies found same-day (SD) discharge rates in TKA populations between 88% and 100% (3,18). With a feasibility rate of 88%, our study confirms previous findings from outside Scandinavia. These high SD discharge rates were not reported in previous Danish studies, showing SD discharge rates between 31% and 34% in unselected TKA patients eligible for outpatient surgery (studies, showing SD discharge rates between 31% and 34% in high SD discharge rates were not reported in previous Danish (3). Another review reported no difference in readmission rate between TKA groups (± discharged on DOS) (4). In contrast, a study (30-day follow-up) found that patients discharged on day 1 and 2 postoperatively had fewer minor and major complications compared with patients discharged on DOS (20). This was not demonstrated in a study (90-day follow-up) estimating that the rate of minor complications was lower for patients discharged on DOS compared with patients not discharged on DOS; the rate of major complications was similar between groups (22). The latter was confirmed by a study with a 1-year follow-up (23). Our study is the first Scandinavian study to assess complications solely in a TKA population. Our study supports the hypothesis that patients discharged on DOS do not experience more severe complications than patients discharged later.

There is a lack of studies reporting PROs when comparing patients undergoing knee arthroplasty discharged on DOS and patients not discharged on DOS (3). Only 1 Danish study has been identified assessing the OKS in these populations. In that study, the OKS was similar at 3- and 12-month follow-up between SD-TKA patients and patients scheduled for discharge on DOS, but who were actually not discharged on DOS (11). In our study, the main reason for not being discharged on DOS was wound seepage/bleeding.

A readmission rate of 3% was found in a review on SD-TKA populations (3). Another review reported no difference in readmission rates between TKA groups (± discharged on DOS) (8). This is supported by 2 studies with 30-day follow-up (19,20). These results were confirmed in studies with 90-day (21,22) and 12-month follow-up (23). A recent Danish study found readmission (90-day follow-up), discharging department visits (3-week follow-up), and telephone calls to other departments and general practitioner (3-week follow-up) to be similar between TKA groups (± discharged on DOS) (12). In contrast to our study, the study found telephone calls to the discharging department to be statistically significant higher in patients discharged on DOS (12).

Overall, our study confirmed previous findings and did not identify differences in unplanned contacts between an SD-TKA group and a standard TKA group.

A review based on 2 comparative studies with 2-year follow-up (4) and 2 studies with 30-day follow-up (10,19) concluded that complication rates were similar in patients discharged on DOS and those not discharged on DOS. Apart from this, the general picture showed a higher rate of post-discharge blood transfusion in the group discharged on DOS in the latter study (19).
matching we succeeded in making the 2 groups comparable on essential variables enabling a reasonable comparative analysis. Second, by using data from the electronic medical records and the DNPR in terms of feasibility, unplanned contacts and complications we reduced the risk of information and selection bias and ensured complete follow-up. Third, the response rate on PROs at 90-day follow-up was satisfying (87%) and although non-responders differed slightly from responders, risk of selection bias is considered low. Finally, by studying the direct effect of a non-controlled daily practice, we strengthened the external validity.

Some limitations warrant consideration. Despite our attempt to identify 2 comparable groups, the main limitation of our study is the non-randomized design. A randomized design is the best way to balance confounding variables, thus improving the validity of the results considerably. Clinical practice within SD-TKA surgery outpaced research as it was introduced faster than we had the opportunity to design and conduct a randomized trial. Still, we found it reasonable to assess SD-TKA surgery using our data, including safety, which is one of the main concerns within SD surgery. We chose a matched design as an alternative to making patients in 2 groups more similar and thus a useful and previously applied way of controlling for confounding in studies in this field (9,19-22). A second limitation is the inclusion criteria for SD-TKA patients, which reflect clinical practice but result in status as a selected group of patients. Thus, the patients accepting SD-TKA might have been advantaged in a biopsychosocial perspective, e.g., in relation to motivation, and this should be remembered when generalizing the results. By including 3 pilot patients and 8 patients with ASA = 3 in the analyzes, we modified the study inclusion criteria in comparison with the predefined clinical inclusion criteria. This was done to reflect clinical practice. Further, in terms of generalizability, providing the total number of patients fulfilling the criteria for SD-TKA surgery could have illustrated the number of patients offered and choosing this option, as well as characteristics of these patients. Unfortunately, this was not registered in the SIKS database. As a third limitation, one could argue that longer follow-up (12 months) could be an advantage but, as part of our aim was to assess feasibility and safety, we consider a 90-day follow-up to be sufficient based on a previous Danish study documenting readmission as occurring within the first 58 days after surgery (9). A final limitation is the relatively small sample size limiting the statistical power to determine differences between groups in terms of rare events such as readmission and related complications. Due to the COVID-19 pandemic during 2020–2022, there has been an urgent need to reduce pressure on hospital wards (24). Consequently, the inclusion criteria for SD-TKA were extended in the clinical setting, and the rate of SD-TKA procedures performed was increased from approximately 15% (March 2019–February 2020) to approximately 35% (March 2020–February 2021). Thus, in the clinical setting the majority of patients are now offered SD-TKA.

In conclusion our data suggests that the SD-TKA procedure is feasible in a selected group of patients. Further, our data suggests similar rates of unplanned contacts and complications, and similar PROs at 90-day follow-up when comparing a SD-TKA group and a standard TKA group.

MG designed the SIKS database and collected the data. AMS, MG, and STS analyzed the data and drafted the manuscript. All authors provided input on the design of the study, interpreted the results, and revised and approved the manuscript.

Helle Kjær Hvildfeldt, RN, is thanked for organizing patient flow, Trine Astrup Bech Vestergaard, physiotherapist, is thanked for providing practical support, and statistician Asger Roer Pedersen is thanked for helpful advice.

Acta Orthopaedica thanks Urban Berg and Tina Størmdal Wik for help with peer review of this study.

Table 1. Description of differences and similarities in the clinical pathway protocol between the SD-TKA group and the standard TKA group

| SD-TKA | Standard TKA |
|--------|--------------|
| **Pre-assessment** | A treatment plan is developed involving the patient and based on a pre-assessment by an orthopedic surgeon, an anesthesiologist, and a nurse. Written patient information and access to the digital platform “My Treatment”, containing animated video instructions. | Identical to SD-TKA |
| **Pre-surgical procedure** | A preoperative information meeting (2 hours) providing oral information on pain management, surgical procedures, post-surgical procedures, and physiotherapy provided by a nurse and a physiotherapist in groups of approximately 20 patients 1–4 weeks prior to surgery. | Identical to SD-TKA |
| **Pre-surgical pain management** | 1 hour prior to surgery in the absence of contraindications, paracetamol 2,000 mg and ibuprofen 400 mg are administered orally. The patients receive spinal anesthesia with 15 mg ropivacaine 5 mg/mL for the surgery and sedation with propofol is provided if requested by the patient. General anesthesia is provided if spinal anesthesia is contraindicated. The systemic analgesics are combined with 8 mg dexamethasone and 4 mg perineural dexamethasone in 2 peripheral nerve blocks: femoral triangle block for pain from the anteromedial aspect of the knee and popliteal plexus block for pain from the posterior aspect of the knee. | Identical to SD-TKA |
| **Surgical procedure** | A dose of tranexamic acid is given pre- and preoperatively. A standard medial parapatellar approach is used with measured resection and implementation of cemented prosthesis CR-PFC (DuPuy) or CR-Triathlon (Stryker). A tourniquet is not applied. Patellar resurfacing only when severe anterior knee pain and/or patellofemoral arthritis. The procedure is performed by 1 of 4 orthopedic surgeons. | Identical to SD-TKA |
| **Post-surgical pain management** | Acetaminophen 1,000 mg and ibuprofen 400 mg are administered orally 4 times daily unless contraindicated during the first 14 days postoperatively. Treatment with mild analgesics is extended if needed. Oral oxycodone 5 mg is administered if needed. Opioid consumption is assessed during hospitalization. At the planned outpatient visit after 14 days postoperatively, a plan is made for weaning off the opioids in cooperation with the patient. | Identical to SD-TKA |
| **Post-surgical procedure** | The patient is transferred to the post-anesthesia care unit (PACU). Radiography is performed before the patient is transferred to the daycare unit. Patients are mobilized by nursing staff, when the effect of the spinal anesthesia has worn off. | The patient is transferred to the PACU and after that to a specialized orthopedic ward. Patients are mobilized by nursing staff, when the effect of the spinal anesthesia has worn off. Radiography is performed before discharge |
| **Physiotherapy** | Physiotherapy is initiated the day after surgery. The content of the physiotherapy session consists of walking with walking aids (often crutches) including stairs if required, allowing full weight-bearing if tolerated by the patient, and instructions in exercises for passive and active range of motion of the knee as well as strengthening exercise for musculus quadriceps against gravity without external weight. Additionally, patients are advised to use long compression stockings during daytime, and rest with the leg elevated several times during the day. If the patient has a stationary bicycle, the patient will be instructed in using this without resistance for several minutes a day. | Physiotherapy is initiated the day after surgery and after that to a specialized orthopedic ward. The content of the physiotherapy session is identical to SD-TKA |
| **Discharge criteria** | Whether discharge criteria are met is assessed by the multidisciplinary team in collaboration with the patient and relatives. | Identical to SD-TKA |
| **Post-discharge procedures** | – A telephone call from a nurse on the first day after surgery | Identical to SD-TKA |
Table 5. Complications in relation to telephone calls, outpatient visits, and readmission (admission to hospital for more than 12 hours)

|                                                | SD-TKA (n = 101) | Standard TKA (n = 101) |
|------------------------------------------------|------------------|------------------------|
| **Complications in relation to telephone calls** |                  |                        |
| Total number of patients                       | 47               | 50                     |
| Total number of telephone calls                | 83               | 81                     |
| Pain management                                | 17               | 38                     |
| Movement, activity and exercise                | 7                | 5                      |
| PICO                                            | 4                | 2                      |
| Wound seepage/bleeding                         | 19               | 6                      |
| Side effects including nausea                  | 10               | 15                     |
| Additional questions about medication           | 2                | 0                      |
| Swelling/compression stocking use              | 18               | 25                     |
| Plaster/bandage                                | 12               | 9                      |
| Other                                           | 6                | 12                     |
| **Complications in relation to outpatient visits** |                  |                        |
| Total number of patients                       | 10               | 9                      |
| Total number of outpatient visits              | 12               | 12                     |
| Pain management                                | 0                | 3                      |
| Movement, activity and exercise                | 0                | 0                      |
| PICO                                            | 6                | 2                      |

* from discharge until the follow-up visit 2 weeks postoperatively.

b 1 telephone call/outpatient visit can concern more than 1 complication.

c PICO is a Single Use Negative Pressure Wound Therapy System.

d admission to hospital for more than 12 hours within the first 90 days after surgery.
Secondary analyses

Secondary analysis 1: The 12 patients from the SD-TKA group not discharged on the day of surgery did not differ from the 89 patients from the SD-TKA group discharged on the day of surgery in relation to age (mean age 66 years) and gender (≈ 45% women).

Secondary analysis 2: When comparing the 89 patients from the SD-TKA group discharged on the day of surgery and the 89 matched patients from the standard group, the results on unplanned contacts (Table 7) and PROs (Table 8) were similar to the primary analysis.

Secondary analysis 3: 13 patients in each group did not complete the PROs at 90-day follow-up. A comparison of those non-responders to the 90-day PRO (n = 26) with responders (n = 176) showed that more women than men had completed the PROs, responders were more often classified as ASA 1+2, and those who had less pain (rest and activity) at baseline were more willing to complete the PROs. In terms of age and OKS at baseline, the 2 groups did not differ.

Table 8. Oxford Knee Score (OKS) and visual analogue scale (VAS) score in the SD-TKA group (n = 89) and the standard TKA group (n = 89)

| Factor                          | SD-TKA | Standard TKA | Between-group mean difference (95%CI) | p-value |
|---------------------------------|--------|--------------|---------------------------------------|---------|
| Function and pain (OKS) (0–48)  |        |              |                                       |         |
| Baseline, mean (SD)             | 24 (7) | 24 (6)       | −0.5 (−2.4 to 1.4)                    | 0.6     |
| 90-day, mean (SD)               | 34 (7) | 34 (7)       | −0.4 (−2.6 to 1.8)                    | 0.7     |
| Within-group mean differences (95% CI) | 10 (7.9–11) | 10 (7.7–12) | −0.1 (−2.6 to 2.5)                    | 1.0     |
| Pain intensity, rest (VAS) (0–100) | | | | |
| Baseline, median (IQR)          | 29 (39) | 44 (39)     |                                       | 0.05    |
| 90-day, median (IQR)            | 7 (14) | 8 (16)       |                                       | 0.4     |
| Median of differences (IQR of differences) | −16 (41) | −28 (39) |                                       | 0.05    |
| Pain intensity, activity (VAS) (0–100) | | | | |
| Baseline, median (IQR)          | 65 (33) | 71 (33)      |                                       | 0.1     |
| 90-day, median (IQR)            | 17 (27) | 15 (23)      |                                       | 0.5     |
| Median of differences (IQR of differences) | −37 (42) | −46 (42) |                                       | 0.1     |

Due to missing values n does not correspond to 89 in the following variables:
Function and pain (Oxford Knee Score): Baseline (SD-TKA n = 86; Standard TKA n = 88), 90-day (SD-TKA n = 75; Standard TKA n = 77), and Within-group mean differences (SD-TKA n = 73; Standard TKA n = 76).

Pain intensity, rest (visual analogue scale): Baseline (SD-TKA n = 77; Standard TKA n = 87), 90-day (SD-TKA n = 77; Standard TKA n = 77), and Median of differences (SD-TKA n = 67; Standard TKA n = 76).

Pain intensity, activity (visual analogue scale): Baseline (SD-TKA n = 80; Standard TKA n = 88), 90-day (SD-TKA n = 77; Standard TKA n = 75), and Median of differences (SD-TKA n = 70; Standard TKA n = 74).
