We consider exciton effects on current in molecular nanojunctions, using a model comprising a two two-level sites bridge connecting free electron reservoirs. Expanding the density operator in the many-electron eigenstates of the uncoupled sites, we obtain a $\times 16$ density matrix in the bridge subspace whose dynamics is governed by Liouville equation that takes into account interactions on the bridge as well as electron injection and damping to and from the leads. Our consideration can be considerably simplified by using the pseudospin description based on the symmetry properties of Lie group SU(2). We study the influence of the bias voltage, the Coulomb repulsion and the energy-transfer interactions on the steady-state current and in particular focus on the effect of the excitonic interaction between bridge sites. Our calculations show that in case of non-interacting electrons this interaction leads to reduction in the current at high voltage for a homodimer bridge. In other words, we predict the effect of “exciton” blocking. The effect of “exciton” blocking is modified for a heterodimer bridge, and disappears for strong Coulomb repulsion at sites. In the latter case the exciton type interactions can open new channels for electronic conduction. In particular, in the case of strong Coulomb repulsion, conduction exists even when the electronic connectivity does not exist.

I. INTRODUCTION

Electron transport through molecular wires has been under intense theoretical (see e.g. 12) and experimental (see e.g. 34) study in the last few years. Theoretical studies usually fall into two categories. The first focuses on the ab-initio computations of the orbitals relevant for the motion of excess charges through the molecular wire 35, while the other 10, 11 employs generic models to gain qualitative understanding of the transport process. At the simplest level 10, 11 the wire Hamiltonian is described by a tight-binding chain composed of $N$ sites with nearest-neighbor coupling (Huckel model) that represents the electron transfer (tunneling) interactions between adjacent sites. This model has been generalized to include Coulomb interactions between electrons on the same site 12 (Hubbard model) and/or electron-phonon interactions 13. In the present paper we investigate another extension of this model, in which we take into account energy transfer interactions between adjacent molecular sites.

Energy-transfer interactions - excitation (deexcitation) of a site accomplished by deexcitation (excitation) of another are well-known in the exciton theory 14, 15. In particular, Frenkel excitons - neutral excited states in which an electron and a hole are placed on the same site are readily transferred between sites, and such intersite interactions can accompany the charge transfer processes as was shown for charge-transfer excitons 17 in (quasi-) one-dimensional structures 18, 19, including polysilanes 20, 22. The latter show a weak coupling between the Frenkel exciton with the admixture of charge transfer states and nuclear motions 21, 22.

In molecular bridges energy-transfer interactions can also sometimes have important effects on charge transfer dynamics. Charge and energy transfer in a linear 2.2′:6.2′-terpyridine-based trimuclear Ru-(II)-Os(II) nanometer-sized array 23, and one-dimensional energy/electron transfer of amylose-encapsulated chain chromophores 24 are examples. In addition, it seems likely that energy transfer takes place in chemically responsive molecular transistors based on a dimer of terpyridyl molecules combined with ion-Co$^{2+}$ 25.

It should be noted that electron transfer is a tunneling process that depends exponentially on the site-site distance, while energy transfer is associated with dipolar coupling that scales like the inverse cube of this distance, and can therefore dominate at larger distances. The importance of the latter stems also from geometric issues, which are related to the dipole-dipole interaction between different sites occurring in the vicinity of metal particles in molecular nanojunctions. Really, Gersten and Nitzan 26, 27 predicted accelerated dipole-dipole energy transfer near a solid particle (see also 28, 29), and in the last time a number of works devoted to the exciton-plasmon interactions have been published 30, 31 that are related to physical effects due to the local field enhancement 32, 33.

*Electronic address: fainberg@hit.ac.il
How will such dipolar interactions affect the conduction properties of molecular junctions? This question was addressed by Galperin, Nitzan and Ratner by the example of a junction composed of one-site-wire and two metal leads \cite{40}, where they predicted the existence of non-Landauer current induced by the electron-hole excitations in the leads. To the best of our knowledge, there were no analog treatment of simultaneous electron and energy transfer (excitons) in multisite bridges. Here we address this problem by using the Liouville-von Neumann equation (LNE) for the total density operator to derive an expression for the conduction of a molecular wire model that contains both electron and energy-transfer interactions. While not a central issue of the present work, we note that energy transfer is closely related to heat transfer through the molecular nanojunction - an issue of important consequences for junction stability and integrity.

Treated separately, the simplest models of exciton and electron transport may be represented by tight-binding transport models, albeit in different representations. Indeed, in the wire Hamiltonian (see Eq.\(3\) below), both the electron- and energy-transfer terms are binary in terms of the annihilation and creation operators for electrons and excitons, respectively. Their simultaneous treatment, however, constitutes a rather complex nonlinear problem. In this work we combine a tight-binding model for electron transport \cite{10,11} with that of one-dimensional Frenkel excitons \cite{14–16} to investigate the effect of energy transfer interaction on electron transport in one-dimensional nanowires. The outline of the paper is as follows. In Sec.\(\text{II}\) we introduce our model and in Sec.\(\text{III}\) we derive a master equation in the eigenbasis of many-electron wire Hamiltonian. Sec.\(\text{IV}\) is devoted to the analytical solution of the problem where we consider both non-interacting electrons at a site and strong Coulomb repulsion at sites. In Sec.\(\text{V}\) we show that the exciton type interactions can open new channels for electronic conduction. In Sec.\(\text{VI}\) we carry out numerical simulations, compare them with the analytical theory and show the existence of the “exciton blocking” effect. We summarize our results in Sec.\(\text{VII}\). In Appendix A we calculate the eigenbasis of many-electron wire Hamiltonian for non-interacting electrons at a site, using the Jordan-Wigner transformation \cite{41}. In Appendix B we present auxiliary calculations.

\section{Model}

We consider a spinless model for a molecular wire that comprises two interacting sites, each represented by its ground, \(|g\rangle\), and excited, \(|e\rangle\), states positioned between two leads represented by free electron reservoirs \(L\) and \(R\) (Fig.\(1\)). The electron reservoirs (leads) are characterized by their electronic chemical potentials \(\mu_L\) and \(\mu_R\), where the difference \(\mu_L - \mu_R = eV_{\text{bias}}\) is the imposed voltage bias. The corresponding Hamiltonian is

\begin{equation}
\hat{H} = \hat{H}_{\text{wire}} + \hat{H}_{\text{leads}} + \hat{H}_{\text{contacts}}
\end{equation}

\begin{equation}
\hat{H}_{\text{leads}} = \sum_{k \in \{L,R\}} \varepsilon_k \hat{c}_k^+ \hat{c}_k
\end{equation}

\begin{equation}
\hat{H}_{\text{wire}} = \sum_{m=1,2} \varepsilon_m \hat{c}_m^+ \hat{c}_m - \sum_{f=g,e} \Delta_f (\hat{c}_2^+ \hat{c}_{1f} + \hat{c}_{1f}^+ \hat{c}_2) + \hbar J (\hat{b}_1^+ \hat{b}_2 + \hat{b}_2^+ \hat{b}_1) + \sum_{m=1,2} U_m N_m (N_m - 1)
\end{equation}

\begin{equation}
\hat{H}_{\text{contacts}} = \hat{V} + \hat{W}
\end{equation}

\begin{equation}
\hat{V} = \sum_{m,f} \hat{V}_{mf} = \sum_{m,f,k \in K_m} V^{(mf)}_k \hat{c}_k^+ \hat{c}_m + H.c.,
\end{equation}

\begin{equation}
\hat{W} = \sum_{m} \hat{W}_m = \sum_{m,k \neq k' \in K_m} \hat{W}^{(m)}_{kk'} b_{k'}^+ b_n^+ + H.c.,
\end{equation}

where \(\hat{c}_m^+ (\hat{c}_m) (m = 1, 2, f = g, e)\) are creation (annihilation) operators for electrons in the different site states of energies \(\varepsilon_m\), while \(\hat{c}_k^+ (\hat{c}_k) (k \in L, R)\) are creation (annihilation) operators for free electrons (energies \(\varepsilon_k\) in the leads \(L\) and \(R\). \(\hat{n}_{mf} = \hat{c}_m^+ \hat{c}_m\) are the occupation operators for the different site states, and site occupation operators are given by \(N_m = \hat{n}_{mg} + \hat{n}_{me}\). The operators \(b_n^+ = \hat{c}_{me}^+ \hat{c}_{mg}\) and \(b_m = \hat{c}_{mg}^+ \hat{c}_{me}\) are excitonic (creation and annihilation) operators on the molecular sites \(m = 1, 2\), while \(b_{kk'} = \hat{c}_k^+ \hat{c}_{k'} = b_{kk'}^+ (k, k' \in L \text{ or } R )\) corresponds to electron-hole pairs in the leads. In the wire Hamiltonian, Eq.\(4\), the \(\Delta_f\) terms represent electron hoping between site states of similar energies (i.e.
between $|g\rangle$ and between $|e\rangle$ states of adjacent molecular sites, the $J$ terms represent exciton hopping (energy transfer) between molecular sites and the $U$ terms correspond to on-site Coulomb interactions. The molecular-leads interactions $\hat{H}_{\text{contacts}}$ are taken to account for two physical processes: $V$ describes electron transfer between the molecular bridge and the leads that gives rise to net current in the biased junction, while $W$ describes energy transfer between the bridge and electron-hole excitations in the leads. In (2) and (3) $K_m$ is the lead closer to the molecular site $m$ ($K_1 = L$, $K_2 = R$) and $H.c.$ denotes Hermitian conjugate. In what follows it will be useful also to define the population operators

$$ \lambda_f = \hat{n}_{2f} + \hat{n}_{1f}$$

in the manifolds of ground ($f = g$) and excited ($f = e$) site levels.

We consider electronic transport through the molecular wire where the leads $K = L, R$ are taken to be each in its own equilibrium characterized by its temperature $T$ (here taken equal for the two leads) and electronic electrochemical potential $\mu_K$. Therefore, the lead electrons are described by the equilibrium Fermi functions $f_k(\varepsilon_k) = [\exp((\varepsilon_k - \mu_K)/k_B T) + 1]^{-1}$. Consequently expectation values for lead operators can be traced back to the expression $\langle \hat{c}^+_k \hat{c}_{k'} \rangle = f_k(\varepsilon_k) \delta_{kk'}$ where $\delta_{kk'}$ is the Kronecker delta. The excitonic operators are equal to $b^+_m = \hat{c}^+_m \hat{c}_m$. The effect of the corresponding interaction in the bridge ($= hJb^+_m b_m + H.c.$) on the charge transport properties is the subject of our discussion.

### III. MASTER EQUATION

Our analysis is based on the LNE, or the generalized master equation for the reduced density matrix of the molecular subsystem, obtained using a standard procedure [10, 11, 42] based on taking $\hat{H}_{\text{contacts}}$ as a perturbation. Briefly, one starts with the LNE for the total density operator and use the projectors of the type $P_K \rho(t) = \rho_K T_K \rho(t)$ in order to derive an equation for the time evolution of the reduced density matrix $\sigma = T_K T_L \rho$. The calculation is facilitated by invoking the so called non-crossing approximation that assumes that the effects of different reservoirs (here $L, R$) and different relaxation processes (here $V, W$) are independent and additive. This leads to

$$ \frac{d\sigma(t)}{dt} = -\frac{i}{\hbar} [\hat{H}_{\text{wire}}, \sigma(t)] - \frac{1}{\hbar^2} Tr_K \int_0^\infty dx [\hat{V}, [\hat{V}^{\text{int}}(-x), \rho(t)]] $$

$$ - \frac{1}{\hbar^2} Tr_K \int_0^\infty dx [\hat{W}, [\hat{W}^{\text{int}}(-x), \rho(t)]] $$

where for any operator $\hat{O}$, $\hat{O}^{\text{int}}$ is the corresponding interaction representation

$$ \hat{O}^{\text{int}}(-x) = \exp[-i \frac{\hbar}{\hbar} (\hat{H}_{\text{wire}} + \hat{H}_{\text{leads}}) x] $$

$$ \hat{O} \exp[i \frac{\hbar}{\hbar} (\hat{H}_{\text{wire}} + \hat{H}_{\text{leads}}) x] $$

and where $Tr_K = Tr_L T_R$.

Consider first terms with the electron transfer interactions $\hat{V}$. Writing the coupling Hamiltonians $\hat{V}_{n f}$ (Eq. 6) as

$$ \hat{V}_{n f} = \hat{c}_{nf} \Lambda^+_n + \hat{c}^+_n \Lambda_{nf} $$

where $\Lambda_{nf} = \sum_{k \in K_n} V^{(nf)}_k \hat{c}_k$, we have $\hat{V}^{\text{int}}(-x) = \hat{c}^{\dagger}_{nf}(-x) \Lambda_{nf}^{\text{int}}(-x) + \hat{c}^+_n \Lambda_{nf}^{\text{int}}(-x)$ with $\Lambda_{nf}^{\text{int}}(-x) = \sum_{k \in K_n} V^{(nf)}_k \hat{c}_k \exp(-i \varepsilon_k x)$.

Similarly, writing the coupling Hamiltonian for energy transfer $W = \sum_n W_n$ as

$$ W_n = b^+_n \Theta_n + b_n \Theta^+_n $$

where $\Theta_n = \sum_{k \neq k' \in K_n} W_{kk'} b_{k'} \hat{c}_k$, then

$$ W^{\text{int}}(-x) = b^+_n \Theta_n^{\text{int}}(-x) + b_n \Theta_n^{\text{int}}(-x) $$

(12)

where

$$ \Theta_n^{\text{int}}(-x) = \sum_{k \neq k' \in K_n} W_{kk'} b_{k'} \exp[i \frac{\hbar}{\hbar} (\varepsilon_{k'} - \varepsilon_k) x] $$

(13)

Bearing in mind that $\rho(t) = \sigma(t) \rho_K$ where $\sigma(t) = Tr_K \rho(t)$ and Eqs. (10), (11) and (12), we get for the second term on the RHS of Eq. (8)

$$ - \frac{1}{\hbar^2} Tr_K \left\{ \int_0^\infty dx [\hat{V}, [\hat{V}^{\text{int}}(-x), \rho(t)]] \right\} = $$

$$ - \frac{1}{\hbar^2} Tr_K \left\{ \int_0^\infty dx [\hat{V}^{\text{int}}(-x) \rho_K \sigma(t)] \right\} $$

$$ - Tr_K [\hat{V} \rho_K \sigma(t) \hat{V}^{\text{int}}(-x)] - Tr_K [\hat{V}^{\text{int}}(-x) \rho_K \sigma(t) \hat{V}] $$

(14)

In evaluating the RHS of Eq. (14) we encounter reservoir correlation functions that reflect the reservoir equilibrium properties as well as the nature of its interaction with the wire. For example,

$$ C_{nf}(-x) = Tr_K [\Lambda_{nf} \Lambda^+_n (-x) \rho_K] $$

$$ = \sum_{k \in K_n} |V^{(nf)}_k|^2 |1 - f_K(\varepsilon_k)| \exp(-i \varepsilon_k x) $$

(15)

Turning to the energy transfer contribution, third term on the RHS of Eq. (8), we obtain an expression of the form (11) with the energy transfer interaction $\hat{W}$ replacing $\hat{V}$. Using the Wick’s theorem, we obtain correlation functions of the type
\[ D_n(-x) = Tr[\Theta_n \Theta_n^*(-x) \rho_{K_n}] \]
\[ = \sum_{k \neq k' \in K_n} |W_{kk'}^{(n)}|^2 f_{K_n}(\varepsilon_k)[1 - f_{K_n}(\varepsilon_{k'})] \exp[i(e_k - e_{k'})x] \]
\[ (16) \]

Below we get a Markovian master equation in the wide-band limit. The full master equation obtained in this way constitutes a set of 256 coupled equations for the 16x16 elements of the wire density matrix, which can be solved numerically by diagonalizing the corresponding Liouvillian matrix. In particular we are interested in the steady state solution, \( \sigma_{SS} \), which is given by the eigenvector of zero eigenvalue. Once \( \sigma_{SS} \) has been found, the current is obtained from
\[ (I) = Tr(\hat{I} \sigma_{SS}) \]
where the current operator (defined, e.g., as the rate of change of electron population on the left of the dashed line in Fig. 1) is given by
\[ \hat{I} = e \frac{d}{dt} \hat{N} = \frac{ie}{\hbar} [\hat{H}, \hat{N}] \]
\[ (18) \]
\[ \hat{N} = \sum_{k \in L} \hat{c}_k^+ \hat{c}_k + \hat{n}_{1g} + \hat{n}_{1e} \]
\[ (19) \]
In section VII we show some results of such numerical calculations. To gain better insight of the transport properties of this model, analytical simplifications in some limits are useful. These are discussed next.

IV. ANALYTICAL EVALUATION

It is known [11] that for the evaluation of Eqs. (8) and (14) it is essential to work in the representation of the eigenstates of the Hamiltonian \( \hat{H}_{wire} + \hat{H}_{leads} \) that defines the zeroth-order time evolution. The use of other representations bears the danger of generating artifacts, which, for instance, may lead to a violation of fundamental equilibrium properties [13]. We thus face the problem of diagonalizing a matrix of order 256. This procedure may be facilitated by using the pseudospin description based on the symmetry properties of Lie group SU(2) as associated with the two state problem \( (1f, 2f) \); \( f = e, g \). Such a “donor acceptor” system may be described by the “charge transfer” operators \( b_f^1 = \hat{c}_{2f}^1 \hat{c}_{1f} \) and \( b_f = \hat{c}_{1f}^+ \hat{c}_{2f} \) that describe intersite charge transfer \( 1 \rightarrow 2 \) and \( 2 \rightarrow 1 \), respectively, in upper and lower states of the molecular dimer. The non-diagonal part of \( \hat{H}_{wire} \), Eq. [13], can then be written in terms of operators \( b_f \) only
\[ \hat{H}_{wire}^{(non\text{diag})} = - \sum_{f = g, e} \Delta_f (b_f^1 + b_f) - \hbar J(b_f^+ b_g + b_f^+ b_e) \]
\[ (20) \]
Define also the pseudospin (Bloch) vector in the second quantization picture
\[ \left( \begin{array}{c} r_f^1 \\ r_f^2 \\ r_f^3 \end{array} \right) = \left( \begin{array}{c} b_f^1 + b_f \\ i(b_f^+ - b_f^0) \\ -\hat{n}_{2f} - \hat{n}_{1f} \end{array} \right); \ f = g, e \]
\[ (21) \]
Its components have the following properties: (a) They satisfy the same commutation rules as Pauli matrices \( \sigma_1, 2, 3 \); (b) the operators \( \lambda_f = \hat{n}_{2f} + \hat{n}_{1f} = \sum_{m=1,2} \hat{c}_{mf}^+ \hat{c}_{mf} \), \( f = e, g \) (cf. Eq. [17]); and \( r_f^1 \) commute: \( [r_f^1, \lambda_f] = 0 \) \( (i = 1, 2, 3) \); (c) any linear operator of the “donor acceptor” system can be written as linear superposition of the operators \( \{ r_f^1 \} \) and \( \lambda_f \). In particular, the wire Hamiltonian can be written as
\[ \hat{H}_{wire} = \frac{1}{2} \lambda_e (\varepsilon_{1e} + \varepsilon_{2e}) + \sum_{f = g, e} \left( \frac{1}{2} r_f^1 (\varepsilon_{2f} - \varepsilon_{1f}) - \Delta_f r_f^1 \right) \]
\[ - \frac{\hbar J}{2} (r_f^1 r_f^1 + r_f^2 r_f^2) + \sum_{m=1,2} U_m N_m (N_m - 1) \]
\[ (22) \]
In Eq. (22) we have put, without loss of generality, \( (\varepsilon_{1g} + \varepsilon_{2g})/2 = 0 \). Because the operators \( \lambda_f \) and \( r_f^1 \) commute, \( \lambda_f \) is conserved under unitary transformations related to the diagonalization of \( \hat{H}_{wire} \). Therefore, a total \( 2^4 \times 2^4 \) space can be partitioned into nine smaller subspaces, i.e., the Liouvillian matrix in the required basis is block diagonal with blocks, according to the values of \( \lambda_f = 0, 1, 2 \) (see Fig 2): four one-dimensional subspaces for \( \lambda_f = 0, 2 \) for either \( f = e, g \) (type I); four two-dimensional subspaces for \( \lambda_f = 1 \) and \( \lambda_f' = 0, 2 \) where \( f \neq f' \) (type II); and one four-dimensional subspace for \( \lambda_e = \lambda_g = 1 \) (type III). The type I submatrix is diagonal, while four state pairs with each pair coupled by the charge transfer interaction are associated with the four \( 2 \times 2 \) blocks of the type II subspace. The remaining four states are coupled by both the charge transfer and exciton transfer interaction and constitute the \( 4 \times 4 \) block of subspace III. Each of these subspaces is characterized by assigning the values \( (\lambda_e, \lambda_g) \) of total populations in the ground and excited states of the two bridge sites.

Using the identity
\[ (r_f^1)^2 = (r_f^2)^2 = (r_f^1)^2 = \lambda_f - 2\hat{n}_{2f}\hat{n}_{1f} = \left\{ \begin{array}{ll} 0 & \text{for} \ \lambda_f = 0, 2 \\ 1 & \text{for} \ \lambda_f = 1 \end{array} \right\} \]
\[ (23) \]
the wire Hamiltonian (22) can be written in the form
\[ \hat{H}_{wire} = \frac{1}{2} \lambda_e (\varepsilon_{1e} + \varepsilon_{2e}) + \sum_{m=1,2} U_m N_m (N_m - 1) + \]
\[ + 0 \quad \text{For subspaces I} \]
\[ + \frac{1}{2} \lambda_f (\varepsilon_{2f} - \varepsilon_{1f}) - \Delta_f r_f^1 \quad \text{For subspaces II} \]
\[ + \frac{1}{2} \sum_{f = g, e} r_f^1 (\varepsilon_{2f} - \varepsilon_{1f}) - \sum_{f = g, e} \Delta_f r_f^1 \]
\[ - \frac{\hbar J}{2} (r_f^1 r_f^1 + r_f^2 r_f^2) \quad \text{For subspace III} \]
\[ (24) \]
where \( \lambda \) current is given by
\[
I = \frac{\mu}{\hbar} \sum_{f=g,e} \langle \beta | f | h_f - b_f^+ \rangle = \frac{\mu}{\hbar} \sum_{f=g,e} \Delta f r_f^f
\]
(25)

Using Eq. (25), this yields
\[
\dot{I} = \frac{e}{\hbar} \sum_{f=g,e} \Delta f r_f^f (\lambda_f = 1)
\]
(26)

Obviously \( \lambda_f = 1 \) in Eq. (26) is another way of saying

\[
\langle \alpha | e_{nf,\alpha}^\text{int} (-x) | \beta \rangle = \left[ \hat{Y}^+ (\lambda_c (\alpha), \lambda_g (\alpha)) \hat{\chi}^+ (\lambda_c (\beta), \lambda_g (\beta)) \right] | \alpha \rangle | \beta \rangle
\]

\[
\times \exp \left[ \frac{i}{\hbar} (E_{\beta} (\lambda_c (\beta), \lambda_g (\beta)) - E_{\alpha} (\lambda_c (\alpha), \lambda_g (\alpha))) x \right]
\]

where \( (\lambda_c (\alpha), \lambda_g (\alpha)) \) denotes the subspace associated with the eigenstate \( \alpha \) and points to the corresponding values of \( \lambda_c \) and \( \lambda_g \), and where \( (\lambda_c (\beta), \lambda_g (\beta)) = (\lambda_c (\alpha) + 1, \lambda_g (\alpha)) \) if \( f = e \) and \( (\lambda_c (\beta), \lambda_g (\beta)) = (\lambda_c (\alpha), \lambda_g (\alpha) + 1) \) if \( f = g \). \( \hat{\chi} \) denotes the transpose matrix \( \hat{\chi} \). The relaxation terms in the master equation (5) take in this basis the forms

\[
- \frac{1}{\hbar^2} \text{Tr}_K \int_0^\infty dx \left[ \hat{\mathcal{V}}^\text{int} (-x) , \rho(t) \right] = \frac{1}{2} \sum_{nf,\alpha'} \Gamma_{nf} \left\{ \hat{c}_{nf,\alpha'\alpha}^+ \sigma_{\alpha'\beta}^+ \hat{c}_{nf,\beta\alpha} - 2 - f_{K_n}(E_{\beta'} - E_{\beta}) \right\}
\]

\[
- f_{K_n}(E_{\alpha'} - E_{\alpha}) + \hat{c}_{nf,\alpha\alpha}^+ \sigma_{\alpha'\beta}^+ \hat{c}_{nf,\beta\alpha} f_{K_n}(E_{\beta'} - E_{\beta'}) + f_{K_n}(E_{\alpha} - E_{\alpha'}) - \hat{c}_{nf,\alpha\alpha}^+ \sigma_{\alpha'\beta}^+ \hat{c}_{nf,\beta\alpha} f_{K_n}(E_{\alpha'} - E_{\beta'})
\]

\[
+ \hat{c}_{nf,\alpha'\alpha}^+ \hat{c}_{nf,\alpha'\beta} (1 - f_{K_n}(E_{\beta'} - E_{\alpha'})) \sigma_{\beta'\beta} - \sigma_{\alpha\alpha} \left\{ \hat{c}_{nf,\alpha'\beta}^+ \hat{c}_{nf,\beta'\beta} f_{K_n}(E_{\beta'} - E_{\alpha'}) + \hat{c}_{nf,\alpha'\beta}^+ \hat{c}_{nf,\beta'\beta} (1 - f_{K_n}(E_{\alpha'} - E_{\beta'})) \right\}
\]

where

\[
\Gamma_{nf} = \frac{2\pi}{\hbar} \sum_{k \in K_n} | V_k^{(nf)} |^2 \delta (\varepsilon_k - \varepsilon_{nf})
\]

(28)
and

\[
-\frac{1}{\hbar^2} Tr_K \int_0^\infty dx |\tilde{W}_x|^2 \rho(t) \big|_{\alpha\beta} \\
= \frac{1}{2} \sum_{n a' a'' b' b''} \{ -B_{K_n}[E_{\alpha'}(\lambda_e + 1, \lambda_g) - E_{\alpha''}(\lambda_e, \lambda_g + 1), \mu_{K_n}] [b_{n, a' a''}^+ b_{n, a'' b'} \sigma_{\alpha' \beta}^+ (t) + \sigma_{\alpha' \beta} (t) b_{n, a' a''}^+ b_{n, a'' b'}] \\
- B_{K_n}[E_{\alpha'}(\lambda_e, \lambda_g + 1) - E_{\beta'}(\lambda_e + 1, \lambda_g), \mu_{K_n}] [b_{n, a' a''}^+ b_{n, a'' b'} \sigma_{\alpha' \beta}^+ (t) + \sigma_{\alpha' \beta} (t) b_{n, a' a''}^+ b_{n, a'' b'}] \\
+ b_{n, a' a''}^+ \sigma_{\alpha' \beta}^+ (t) b_{n, a'' b'} B_{K_n}[E_{\beta'}(\lambda_e, \lambda_g + 1) - E_{\beta}(\lambda_e + 1, \lambda_g), \mu_{K_n}] \\
+ b_{n, a' a''}^+ \sigma_{\alpha' \beta}^+ (t) b_{n, a'' b'} B_{K_n}[E_{\alpha'}(\lambda_e, \lambda_g + 1) - E_{\alpha}(\lambda_e + 1, \lambda_g), \mu_{K_n}] \\
+ b_{n, a' a''}^+ \sigma_{\alpha' \beta}^+ (t) b_{n, a'' b'} B_{K_n}[E_{\alpha'}(\lambda_e + 1, \lambda_g) - E_{\alpha}(\lambda_e, \lambda_g + 1), \mu_{K_n}] \}
\]

(29)

where

\[
B_{K_n}(E_\alpha - E_\beta, \mu_{K_n}) = \frac{2\pi}{\hbar} \sum_{k \neq k' \in K_n} \left| W_{nk'}^{(n)} \right|^2 \delta(\varepsilon_k - \varepsilon_{k'} + E_\alpha - E_\beta) f_{K_n}(\varepsilon_k) [1 - f_{K_n}(\varepsilon_{k'})]
\]

(30)

In evaluating these forms we have taken the wide band limit for the electrodes spectral densities.

Next consider the diagonalization procedure itself. In subspaces I the unitary transformation \( Y(\lambda_e, \lambda_g) \) is obviously the unity matrix. The diagonalization of the block matrices in subspaces II and III is carried out in the limiting cases of zero and infinite on-site interactions.

### A. Zero on site coupling

The case of zero on site coupling is discussed in Appendix A. We find the eigenfunctions and energies of the 2-site bridge summarized in Table I.

| \( \lambda_e = 0 \) | \( \Phi(0, 0) = \) | \( |0_{1g}, 0_{2g}, 0_{1e}, 0_{2e} \rangle \) | \( E = 0 \) |
| \( \lambda_e = 1 \) | \( \Phi_{\pm}(1, 0) = \) | \( \frac{1}{\sqrt{2}} (|0_{1g}, 0_{2g}, 0_{1e}, 0_{2e} \rangle \mp |0_{1g}, 0_{2g}, 1_{1e}, 0_{2e} \rangle) \) | \( E = \varepsilon_{2e} \pm \Delta_e \) |
| \( \lambda_e = 2 \) | \( \Phi(2, 0) = \) | \( |0_{1g}, 0_{2g}, 1_{1e}, 0_{2e} \rangle \) | \( E = \varepsilon_{1e} + \varepsilon_{2e} \) |

where \( \Phi_{\pm}(1, 0) = \frac{1}{\sqrt{2}} \left( \begin{array}{c} \sin \tau - \cos \tau - \cos \tau \sin \tau \\ \cos \tau \sin \tau \sin \tau \cos \tau \\ \sin \tau \cos \tau - \cos \tau - \sin \tau \\ \cos \tau - \sin \tau & \sin \tau & - \cos \tau \end{array} \right) \)

(31)

and where \( \tau \) is given by

\[
\cos 2\tau = -\frac{J_0}{\sqrt{4\Delta_e^2 + J_0^2 \hbar^2}} \quad \text{and} \quad \sin 2\tau = \frac{2\Delta_e}{\sqrt{4\Delta_e^2 + J_0^2 \hbar^2}}
\]

(32)
The current in this case is found to be
\[
\langle I \rangle = \frac{2e}{\hbar} \Delta \text{Im} \{ [\sigma(1, 1) + \sigma(1, 1)] \cos 2\tau \\
+ [\sigma(1, 1) - \sigma(1, 1)] \sin 2\tau - \sum_{\lambda_g=0.2} \sigma_{+-}(1, \lambda_g) \} 
\]
(33)

Indices ”+” and ”−” in Eq. (33) correspond to the functions \( \Phi^+ \) and \( \Phi^- \), respectively, in Table 1. Indices 1, 2, 3 and 4 label the the eigenstates of the wire Hamiltonian in subspace III. The corresponding energies are given by formulas \( E_1 = E_{-+} \), \( E_2 = E_{--} \), \( E_3 = E_{+-} \), \( E_4 = E_{++} \), where
\[
E_{\pm, \pm} = \varepsilon_{\pm} \pm \frac{1}{2} J \hbar \pm \frac{1}{2} \sqrt{4\Delta^2 + J^2\hbar^2 (34)}
\]

B. Rotating-wave approximation

The calculation of the non-diagonal elements of the density matrix \( \sigma_{ab}(1, \lambda_g) \) in Eq. (33) for the current is essentially simplified for very weak wire–lead coupling when the coherent time-evolution dominates the dynamics of the wire electrons. This means that the largest time-scale of the coherent evolution, given by the smallest energy difference, and the dissipative time-scale, determined by the electron and energy transfer rates, \( \Gamma_{nf} \) and \( B_{K_n} \), is well separated, i.e., 
\[ h\Gamma_{nf}, |hB_{K_n}| \ll |E_n - E_\beta| \] for \( \lambda_g = 1 \) and \( \alpha \neq \beta \). Then for \( \lambda_g = 1 \) and \( \alpha \neq \beta \), Eq. (3) is dominated by the first term on the RHS. Consequently, \( \sigma_{ab}(1, \lambda_g) \) can be calculated in the first order of \( h\Gamma_{nf}/(E_n - E_\beta) \) and \( \hbar B_{K_n}/(E_n - E_\beta) \). This constitutes the essence of a rotating-wave approximation (RWA) [11]. Within it, one can provide a closed expression for the reduced density matrix elements \( \sigma_{ab} \) and for the stationary current. We shall use the RWA below in Sec. V and Appendix B.

C. Strong Coulomb repulsion at sites

In the limit of strong Coulomb repulsion, \( U_m \) is assumed to be so large that at most one electron resides on each site. Thus, the available Hilbert space for uncoupled sites is reduced to three states \( \tilde{\chi}(0, 0) = |0_{1g} 0_{2g}, 0_{1e}, 0_{2e} \rangle \), \( \tilde{\chi}(2, 0) = |0_{1g} 0_{2g}, 1_{1e}, 1_{2e} \rangle \) and \( \tilde{\chi}(0, 2) = |1_{1g} 1_{2g}, 0_{1e}, 0_{2e} \rangle \) for subspaces I; two states \( \tilde{\chi}(1, 0) = |0_{1g} 0_{2g}, 0_{1e}, 0_{2e} \rangle \) and \( \tilde{\chi}(0, 1) = |0_{1g} 1_{2g}, 0_{1e}, 0_{2e} \rangle \) for subspaces II; and the state \( \tilde{\chi}(1, 1) = |1_{1g} 0_{2g}, 0_{1e}, 1_{2e} \rangle \) and \( \tilde{\chi}(1, 1) = |0_{1g} 1_{2g}, 1_{1e}, 0_{2e} \rangle \) for the now 2-dimensional subspace III. The unitary operators \( \hat{Y}^{\pm}(1, 0) \) and \( \hat{Y}^{\pm}(0, 1) \) and the corresponding eigenstates and eigenvalues are defined by the same Eqs. (16), (17) and (18), respectively, as before (see Appendix A). The operator \( \hat{Y}^{\pm}(1, 1) \) is reduced to (see Appendix B)
\[
\hat{Y}^{\pm}(1, 1) = \frac{1}{\sqrt{2}} \left( \begin{array}{cc} 1 & 1 \\ -1 & 1 \end{array} \right) 
\]
(35)

The current in this case is
\[
\langle I \rangle = \frac{2e}{\hbar} \Delta \text{Im} \{ [\sigma(0, 1) + \sigma(2, 1)] \cos 2\tau \\
+ [\sigma(0, 1) - \sigma(2, 1)] \sin 2\tau - \sum_{\lambda_g=0.2} \sigma_{+-}(1, \lambda_g) \} 
\]
(36)

V. CURRENT FROM THE ENERGY TRANSFER INTERACTION IN THE WIRE

In a recent paper [40], Galperin, Nitzan and Ratner have predicted the existence of non-Landauer current induced by energy transfer interactions between a bridge molecule and electron-hole excitations in the leads. Here we show that a similar non-Landauer current arises from the exciton type interaction \( J \) in the wire itself. For simplicity we limit ourselves to electron transfer interaction between the wire and the metal leads, Eq. (27), and disregard the corresponding excitation transfer, Eq. (29). Also for simplicity we consider a large bias limit in the Coulomb blockade case when \( \mu_L > \varepsilon_e \) and \( \mu_R < \varepsilon_g \), and the states \( \varepsilon_e, \varepsilon_g \) are positioned rather far \( \gg \hbar \gamma J/|J_e| \) from the Fermi levels of both leads so that \( f_L(e) = 1 \) and \( f_R(e) = 0 \) can be taken on the RHS of Eq. (27). Finally, we disregard electron transfer interaction in the ”g” channel, i.e. we take \( \Delta_g = 0 \). Landauer type current would be realized in channel ”e” when it is isolated from channel ”g”, i.e. when \( J = 0 \), \( \Gamma_{1g} = \Gamma_{2g} = 0 \) and \( \lambda_g = 0 \). Solving Eqs. (3), (27) in the RWA approximation under these conditions and substituting the steady-state solution into Eq. (39), we get, using also the normalization condition \( \sum_{\lambda_e=0,1,2} Tr\sigma(\varepsilon_e,0) = 1 \),
\[
\langle I \rangle_{\text{RWA}} = -\varepsilon_e \frac{\Gamma_{1e}\Gamma_{2e}}{\Gamma_{1e} + \Gamma_{2e}} 
\]
(37)

Eq. (37) describes the Landauer current and coincides with Eq. (21) of Ref. [11] (excluding the sign).

In fact, the current vanishes for \( \Gamma_{1e} = \Gamma_{2e} = 0 \) even when \( \Gamma_{1g}, \Gamma_{2g} \neq 0 \), since \( \Delta_g = 0 \) (see Fig. 1). Such selective coupling to the leads could be obtained for the bridge made of a quadrupole quantum dot where the lateral ones are strongly coupled to the leads [17, 48].

Consider now the case when \( \Gamma_{1e} = \Gamma_{2e} = 0 \); \( \Gamma_{1g}, \Gamma_{2g} \neq 0 \); \( \Delta_e = 0 \) and \( J \neq 0 \). For this case Eqs. (8), (27) together with Eq. (36) lead to
\[
\langle I \rangle = -4\varepsilon_J J_e \Delta_g^2 \frac{1 - [\sigma_{--}(0, 1) + \sigma(2, 0)]}{\Delta_g^2 + 16\Delta_g^2 J^2 + \hbar^2 \gamma^2 J^2} 
\]
(38)
leads.

c) the intersite charge transfer, \( \sigma |g\rangle \), where only \( |g\rangle \) levels are coupled to the leads.

FIG. 4: Different stages of the energy-transfer induced current. a) energy transfer, \( \sigma (1, 1) \neq 0 \). b) the charge transfer to the right lead. c) the intersite charge transfer, \( \sigma (1, 0) \neq 0 \); the charge transfer from the left lead.

where for simplicity we put \( \Gamma_{1g} = \Gamma_{2g} \equiv \Gamma_g \). Eq.\( (38) \) describes a non-Landau current caused by transport in different channels: the intersite transfer occurs in channel "c", and the charge transfer between the molecular bridge and the leads occurs in channel "g". The inter-channel mixing is induced by the energy-transfer term \( J \) (see Fig\text{4}). For example, starting with the molecular system in state \( |1_{1g}, 0_{2g}, 0_{1e}, 1_{2e}\rangle \), electron transmission takes place along route such as \( |1_{1g}, 0_{2g}, 0_{1e}, 1_{2e}\rangle \xrightarrow{1} |0_{1g}, 1_{2g}, 0_{1e}, 0_{2e}\rangle \xrightarrow{2} |0_{1g}, 0_{2g}, 1_{1e}, 0_{2e}\rangle \xrightarrow{3} |1_{1g}, 0_{2g}, 0_{1e}, 1_{2e}\rangle \). Step 1 is an energy transfer process, steps 2 and 3 rely on \( \Gamma_{2g} \neq 0 \) and \( \Delta_e \neq 0 \), respectively, and step 4 closes the circle via the \( \Gamma_{1g} \) process.

Eq.\( (38) \) clearly shows that the current exists only for \( J \neq 0 \) and \( \Delta_e \neq 0 \). For small \( J \), \( \langle I \rangle \sim J^2 \). For large \( J \) we obtain

\[
\langle I \rangle \approx -4e\Gamma_g \Delta_e \frac{1 - [\sigma_-(0, 1) + \sigma(2, 0)]}{16\Delta_e^2 + \hbar^2 \Gamma_g^2}
\] (39)

which does not depend on \( J \). In the limit \( \hbar |J|, |\Delta_e| \gg \Gamma_g \), Eq.\( (38) \) yields for \( \sigma_-(0, 1) = \sigma(2, 0) = 0 \)

\[
\langle I \rangle_{RWA} = -\frac{e}{2\Gamma_{2g} + \Gamma_{1g}} \frac{\Gamma_{2g} \Gamma_{1g}}{\Gamma_g}
\] (40)

In deriving Eq.\( (40) \) we have not put \( \Gamma_{1g} = \Gamma_{2g} \). This limit corresponds to the range of validity of the RWA. Indeed, it can be shown that Eq.\( (40) \) can be obtained for this model in the RWA (see Appendix C).

If \( \sigma_-(0, 1), \sigma(2, 0) \neq 0 \), the non-Landau current decreases, since the populations of states \( |1_{1g}, 0_{2g}, 0_{1e}, 0_{2e}\rangle \) (\( \sigma_-(0, 1) \)) and \( |0_{1g}, 0_{2g}, 1_{1e}, 1_{2e}\rangle \) (\( \sigma(2, 0) \)) suppress current. Two latter states are also steady-states in the case under consideration (Coulomb blocking, \( \Gamma_{1e} = \Gamma_{2e} = \Delta_g = 0 \)) along with the states described by Fig\text{4}. The existence of several steady-states corresponds to the presence of the respective zero eigenvalues of the relaxation matrix. Our numerical calculations give three such zero eigenvalues corresponding to three above steady-states.

If \( \Gamma_{1e}, \Gamma_{2e} \neq 0 \), state \( |1_{1g}, 0_{2g}, 0_{1e}, 0_{2e}\rangle \) is only steady-state that “locks” the current due to Coulomb blocking, since \( \Delta_g = 0 \). Numerical simulations of other situations when \( \Delta_g \neq 0 \) and non-interacting electrons at a site are carried out in the next section.

VI. NUMERICAL RESULTS

The results presented in this section are based on direct numerical solution of Eq.\( (35) \), and are in complete agreement with the analytical solutions when applied to the special cases treated in Sections IV and V. The numerical solution was carried using the the basis of eigenstates of the Hamiltonian \( H_{wire} \), Eq.\( (3) \). Once \( \sigma(t) \) is obtained from Eq.\( (38) \), the expectation value of the current is calculated as \( \langle I \rangle = Tr(\hat{I}\sigma(t)) \) where the current operator was defined by Eq.\( (29) \). In this calculation we have limited ourselves to the case where the wire-leads energy transfer coupling \( \hat{W} \) is disregarded and, unless otherwise specified, have used the following parameters: \( \varepsilon_{1g} = \varepsilon_{2g} = 0.0\,eV \), \( \varepsilon_{1e} = \varepsilon_{2e} = 2.0\,eV \), \( \Delta_g = \Delta_e = 0.01\,eV \), \( \Gamma_{1f} = \Gamma_{2f} = 0.02\,eV \) for \( f = g, e \)
We also used the value of $e\Delta_e/h = 2.45 \times 10^{-6}$ A as the unit of current $\langle I \rangle$.

Consider first non-interacting electrons. Figs. 5, 6 and 7 show the expectation value of the current $\langle I \rangle$ and one-particle populations $P_{n,f} = Tr(\hat{\sigma}_n \hat{P}_f \sigma)$ as functions of the exciton interaction parameter $J$. One can see that if the imposed voltage bias $V_{bs}$ is larger than $\varepsilon_e - \varepsilon_g$, the expectation value of the current diminishes when $|J|$ increases (we have used $J < 0$ which is typical to J-aggregates, however the trend is similar with $J > 0$). Such a behavior can be understood, using Eq.(34) for the hopping matrix element $\Delta_e$. This leads to $\langle I \rangle$ as a function of the parameter $J$ in the case of non-interacting electrons for $V_{bs} = 0.40eV$. The current $\langle I \rangle$ is shown in left panel, and the populations $P_{g}, P_{1g}, P_{2g}$ and $P_{3g}$ are shown in the right panel.

The Fermi levels were taken to be equal to $V = 0$. Since $E_{-} - E_{+} = -2\Delta_e$, the contribution of the third term on the RHS of Eq. (33) for the steady-state condition can be evaluated as $\sigma_{\alpha \beta} \sim \sqrt{h/\Delta_e}$ (see also Sec.IV B). The replacement of $2e\Delta_e/h \sum_{\lambda_y=0,2} \sigma_{+-}(1, \lambda_y) \sim 2e\Gamma$ (41)

The contribution of the first and the second terms on the RHS of Eq. (33) depends on the relation between $J$ and $\Delta_e$

When $h/|J| \ll \Delta_e$, Eq. (42) yields $\cos 2\tau \approx 1$, $\sin 2\tau \approx 1$, and only the second term in (33) gives a contribution to $\langle I \rangle$. Under this condition one gets from Eq. (34) two doubly-degenerated states 4 and 1 due to the exciton interaction (indices $\alpha \beta$).

In opposite case, $h/|J| \gg \Delta_e$, $\cos 2\tau \approx 1$ (again we use $J < 0$ - as in J-aggregates) and $\sin 2\tau \approx 0$. In this case only the first term in (33) contributes to the current from the states of subspace (III). For this case we get $E_2 \approx E_4 \approx \varepsilon_e$ and $E_{1g} \approx \varepsilon_e + |Jh|$. This leads to $\langle I \rangle$ as a function of the parameter $J$ in the case of non-interacting electrons for $V_{bs} = 0.40eV$. The current $\langle I \rangle$ is shown in left panel, and the populations $P_{g}, P_{1g}, P_{2g}$ and $P_{3g}$ are shown in the right panel.
total current to decrease. In other words, the transitions $3 \rightarrow 2$ and $4 \rightarrow 1$ do not participate in electron transfer due to their large splitting for $\hbar |J| \gg \Delta_e$. This is in a sense “exciton blocking” of electron transmission through the bridge.

Next we turn to situations where electron-electron interaction is taken into account. Fig. 8 shows the current $\langle I \rangle$ as a function of the Coulomb interaction parameter $U_1 = U_2$. Fig. 9 depicts the current $\langle I \rangle$ as a function of the bias voltage $V_{bs}$ for different values of the exciton coupling $J$ for the case of non-interacting electrons as well as for the case of infinite on-site interaction between electrons. The “exciton blocking” effect seen for non-interacting electrons (smaller current for larger $|J|$) disappears in the case of Coulomb blocking.

This is supported by Eq. (46) that does not show a direct contribution of the states of subspace (III) to the current, and the above evaluation of the term $\frac{2\pi}{\hbar} \Delta_s \text{Im} \sigma_{-+}(1,0)$. The point is that in the case of interacting electrons, subspace (III) includes only states, which are acted upon exciton interaction (see Fig. 2). Moreover, in the case of Coulomb blocking, the effect of exciton-induced current exists (Sec. V).

The effect of “exciton blocking” depends on the energy detuning $\varepsilon_{2f} - \varepsilon_{1f}$ in channel “f” for a heterodimer bridge. Figs. 10 and 11 show the current $\langle I \rangle$ as a function of $J$ for $\varepsilon_{2c} - \varepsilon_{1c} = 0.1eV$. $\langle I \rangle$ is seen to increase for small $|J|$, then to decrease as $|J|$ becomes larger. This can be related to the modification of resonance conditions when $\varepsilon_{2c} - \varepsilon_{1c} \neq 0$.

Finally, figures 12, 13, 14 and 15 show more of the system behavior for the model with $U_1, U_2 = \infty$. Fig. 12 shows the current as a function of $|J|$ for different values of the imposed voltage bias $V_{bs}$. If $V_{bs}$ is large compared to the energy difference between the excited and ground site energies, the current behaves in accordance with Eq. (48). If $V_{bs}$ is close to this energy difference, the current increases initially with $|J|$, and then decreases to zero. Furthermore, in accordance with Eq. (48), the left panel of Fig. 14 shows that the steady-state current is zero for the initial condition $\sigma_{-+}(0, 1) = 1$. The steady-state current is zero also for the initial condition $\sigma(0, 0) = 1$, since the latter state relaxes to $\sigma_{-+}(0, 1) = 1$. Figures 13

![FIG. 8: The current $\langle I \rangle$ as a function of the Coulomb interaction parameter $U_1 = U_2$. $V_{bs} = 2.0eV$ (solid line); $V_{bs} = 4.0eV$ (dashed line); $V_{bs} = 8eV$ (dotted+ dashed line); $J = 0.0eV$ (left panel) and $J = -0.05eV$ (right panel).](image)

disregarded. We used a model comprising a two two-level sites bridge connecting free electron reservoirs. Expanding the density operator in the many-electron eigenstates of the uncoupled sites, we obtain a $16 \times 16$ density matrix in the bridge subspace whose dynamics is governed by Liouville equation that takes into account interactions on the bridge as well as electron injection and damping to and from the leads. Our consideration has been considerably simpliﬁed by using the pseudospin description based on the symmetry properties of Lie group $SU(2)$. We studied the inﬂuence of the bias voltage, the Coulomb repulsion and the energy-transfer interaction on the steady-state current and in particular focus on the effect of the excitonic interaction between bridge sites. Our calculations show that in the case of non-interacting electrons this interaction leads to reduction in the current at high voltage for a homodimer bridge. This effect can be called “exciton” blocking. The effect of “exciton” blocking is modiﬁed for a heterodimer bridge, and disappears for strong Coulomb repulsion at sites. In the

VII. CONCLUSION

We have developed a theory of electron transport through a molecular wire in the presence of the effect of dipolar energy-transfer interaction between the sites in the wire. We found that such interaction, which leads to exciton excitations in the wire, cannot in general be disregarded. We used a model comprising a two two-level sites bridge connecting free electron reservoirs. Extending the density operator in the many-electron eigenstates of the uncoupled sites, we obtain a $16 \times 16$ density matrix in the bridge subspace whose dynamics is governed by Liouville equation that takes into account interactions on the bridge as well as electron injection and damping to and from the leads. Our consideration has been considerably simpliﬁed by using the pseudospin description based on the symmetry properties of Lie group $SU(2)$. We studied the inﬂuence of the bias voltage, the Coulomb repulsion and the energy-transfer interaction on the steady-state current and in particular focus on the effect of the excitonic interaction between bridge sites. Our calculations show that in the case of non-interacting electrons this interaction leads to reduction in the current at high voltage for a homodimer bridge. This effect can be called “exciton” blocking. The effect of “exciton” blocking is modiﬁed for a heterodimer bridge, and disappears for strong Coulomb repulsion at sites. In the
latter case the exciton type interactions can open new channels for electronic conduction. In particular, in the case of strong Coulomb repulsion, conduction exists even when the electronic connectivity as defined above does not exist.

To end this discussion we note that in this work we have investigated a molecular bridge connecting metal leads. It is worthy to note that the geometry considered could modify the effect of dipolar energy-transfer interaction between the sites in the wire [20]. This issue will be considered elsewhere.

VIII. APPENDIX A. NON-INTERACTING ELECTRONS AT A SITE

The unitary transformations \( \hat{Y}(\lambda_e, \lambda_j) = I \) for subspaces (I). As to subspaces (II), Hamiltonian corresponding to the second line of the RHS of Eq. (21) where \( \lambda_f = 1 \neq \lambda_f' (f' \neq f) \) can be diagonalized, using the unitary transformation

\[
\begin{pmatrix}
R_{1f}^f \\
R_{2f}^f \\
R_{3f}^f
\end{pmatrix} = \hat{T}^f \begin{pmatrix}
r_{1f}^f \\
r_{2f}^f \\
r_{3f}^f
\end{pmatrix} = \begin{pmatrix}
\cos 2\theta_f & 0 & -\sin 2\theta_f \\
0 & 1 & 0 \\
\sin 2\theta_f & 0 & \cos 2\theta_f
\end{pmatrix} \begin{pmatrix}
r_{1f}^f \\
r_{2f}^f \\
r_{3f}^f
\end{pmatrix}
\]

where

\[
\cos 2\theta_f = \frac{\varepsilon_{2f} - \varepsilon_{1f}}{\sqrt{(\varepsilon_{2f} - \varepsilon_{1f})^2 + 4\Delta_f^2}}, \\
\sin 2\theta_f = \frac{-2\Delta_f}{\sqrt{(\varepsilon_{2f} - \varepsilon_{1f})^2 + 4\Delta_f^2}}
\]

The matrix elements of \( \hat{T}^f \) are connected with the unitary transformations \( \hat{Y}(\lambda_e, \lambda_j) \) for subspaces (II) by formula \( T_{nj}^f = (1/2)TR(\hat{\sigma}_n \hat{Y}^+ \hat{\sigma}_j \hat{Y}) \) where \( \hat{\sigma}_n \) and \( \hat{\sigma}_j \) are Pauli matrices.

A. Unitary transformations for subspaces (II)

Consider subspaces (II). In the limit \( U_m = 0 \), the matrix \( \hat{T}^f \), Eq. (44), with matrix elements \( T_{nj}^f = (1/2)TR(\hat{\sigma}_n \hat{Y}^+ \hat{\sigma}_j \hat{Y}) = (1/2)TR(\hat{\sigma}_n \hat{Y}^+ \hat{\sigma}_j \hat{Y}) \) describes a rotation by mixing angle \( 2\theta_f \) around axis “y”. \( \hat{Y}(\lambda_f = 1; \lambda_f' = 0, 2) \) is an unitary operator defined by

\[
\hat{Y}^+(\lambda_f = 1; \lambda_f' = 0, 2) = \begin{pmatrix}
\cos \theta_f & \sin \theta_f \\
-\sin \theta_f & \cos \theta_f
\end{pmatrix}
\]

which enables us to obtain eigenstates

\[
\begin{pmatrix}
\Phi_+(\lambda_f = 1; \lambda_f' = 0, 2) \\
\Phi_-(\lambda_f = 1; \lambda_f' = 0, 2)
\end{pmatrix} = \hat{Y}^+(\lambda_f = 1; \lambda_f' = 0, 2) \times \hat{\chi}(\lambda_f = 1; \lambda_f' = 0, 2)
\]

and eigenvalues

\[
E_{\pm}(\lambda_f = 1; \lambda_f' = 0, 2) = \frac{1}{2}[(\varepsilon_{1e} + \varepsilon_{2e}) + (\varepsilon_{2f} - \varepsilon_{1f}) \pm \sqrt{(\varepsilon_{2f} - \varepsilon_{1f})^2 + 4\Delta_f^2}]
\]

for subspaces (II). Here the many-electron eigenstates of the uncoupled sites are given by \( \hat{\chi}(1,0) = \begin{pmatrix}
0_{g}^f, 0_{g}^f, 0_{1e}, 1_{2e}
\end{pmatrix} , \hat{\chi}(0,1) = \begin{pmatrix}
0_{1g}, 1_{2g}, 0_{1e}, 0_{2e}
\end{pmatrix} , \hat{\chi}(1,2) = \begin{pmatrix}
0_{1g}, 0_{2g}, 1_{1e}, 1_{2e}
\end{pmatrix} \) and \( \hat{\chi}(2,1) = \begin{pmatrix}
1_{1g}, 1_{2g}, 0_{1e}, 1_{2e}
\end{pmatrix} \).

Taking the expectation value of the current, Eq. (20), we get

\[
\langle I \rangle = \frac{2e}{\hbar} \sum_{\lambda_f' = 0;2} \Delta_f \text{Im} \sigma_{-}^+(\lambda_f = 1; \lambda_f') - \sum_{\alpha\beta} \text{Im} \sigma_{\alpha \beta}^+(1,1) \times \langle \hat{Y}^+(1,1) \hat{Y}^+(1,1)(\Delta_e b_e + \Delta_g b_g) \hat{\chi}(1,1) \hat{Y}(1,1) \alpha \beta \rangle
\]

where we put \( r_{2f}^f = R_{2f}^f \) for \( \lambda_f = 1 \) and \( \lambda_f' = 0, 2 \) that follows from Eq. (44) and used \( \langle R_{2f}^f(\lambda_f = 1; \lambda_f' = 0, 2) = TR(\hat{\sigma}_2 \sigma) = 2 \text{Im} \sigma_{-}^+(\lambda_f = 1; \lambda_f' = 0, 2) \). Indices “+” and “−” in Eq. (49) correspond to the functions \( \Phi_+(1, \lambda_g) \) and \( \Phi_-(1, \lambda_g) \), respectively, in Table I.

B. Unitary transformation for subspace (III)

The calculation of \( \hat{Y}^+(1,1) \) is more involved. Consider for brevity a homodimer bridge with \( \varepsilon_{ng} = 0, \varepsilon_{ne} = \varepsilon_c \) and \( \Delta_g = 0 \). Bearing in mind future generalizations of our model to \( N \)-sites, we shall transform the Paulion operators \( (b_c^+, b_f) \) to fermion operators \( (\beta_c^+, \beta_f) \) through the Jordan-Wigner transformation \[41, 42, 50]:

\[
\beta_c = b_c, \quad \beta_c^+ = b_c^+ , \beta_g = \exp(i\pi b_c^+ b_e) b_g, \\
\beta_g^+ = b_c^+ \exp(-i\pi b_c b_e)
\]

Then \( \hat{H}_{wire} \), Eqs. (39) and (20), can be rewritten for subspace (III) in terms of the fermion operators as

\[
\hat{H}_{wire}(\varepsilon_c = \lambda_g = 1) = \varepsilon_c - \Delta_e (\beta_c^+ \beta_c - \beta_c \beta_c^+) - \hbar J (\beta_e^+ \beta_g + \beta_g^+ \beta_e)
\]
Eq. (51) is a quadratic in Fermi operators and can be diagonalized in two stages. Its “excitonic” part $\hat{H}_{ex} = -\hbar J (\beta^+_e \beta_g + \beta^+_g \beta_e)$ is readily transformed to satisfy the condition $\hat{H}_{ex} = \sum_j \hbar \epsilon_j a_j^+ a_j$ if we take

$$a_j = \sqrt{2/3} (\beta_g \sin \frac{\pi j}{3} + \beta_e \sin \frac{2\pi j}{3}),$$

$$\epsilon_j = -2J \cos \frac{\pi j}{3}, \quad j = 1, 2$$

(52)

where $a_j$ are also Fermi operators. The corresponding occupation number basis set contains $2^2 = 4$ eigenfunctions of the system. The single-excited states are given by Eqs. (31) and (32), $\hat{\Phi}(1) = \langle \epsilon | \phi_{1e} \phi_{1g} | eg \rangle = \frac{1}{2} \langle (-1)^{j_2} - (-1)^{j_1} \rangle |eg\rangle$

$$a_j^+ a_j^+ |0\rangle = \left| \begin{array}{c} \phi_{1e} \\ \phi_{1g} \\ \phi_{2e} \\ \phi_{2g} \end{array} \right| |eg\rangle = \frac{1}{2} \langle (-1)^{j_2} - (-1)^{j_1} \rangle |eg\rangle$$

(53)

with energy $\epsilon_1 + \epsilon_2 = 0$ equal to that of the vacuum state where $|eg\rangle \equiv |0_{1g}, 1_{2g}, 0_{1e}, 1_{2e}\rangle$. The wire Hamiltonian can be written down in terms of $a_j$ as $\hat{H}_{wire}(\lambda_e = \lambda_g = 1) = \epsilon_e + \sum_j \hat{H}_j$, where $\hat{H}_j = \hat{F}_j + (-1)^j \hbar J a_j^+ a_j$, $\hat{F}_j = (-1)^j (\Delta_e / \sqrt{2}) (a_j^+ + a_j)$ is the “hopping” operator with the only nonzero matrix elements involving states which differ by a single excitation: $\langle 0 | \hat{F}_j a_j^+ |0\rangle = (-1)^j \Delta_e / \sqrt{2}$, $\langle 0 | a_j^+ \hat{F}_j a_j^+ |0\rangle = (-1)^j \Delta_e / \sqrt{2}$. The eigenstates and eigenvalues of $\hat{H}_{wire}(\lambda_e = \lambda_g = 1)$ can be calculated now as follows. $\hat{\Phi}(1, 1) = Y^+(1, 1) \chi(1, 1)$ where $Y^+(1, 1)$ is given by Eqs. (31) and (32), $\chi(1, 1) = \left( \begin{array}{c} |0\rangle \\ |e\rangle \\ |g\rangle \\ |eg\rangle \end{array} \right)$, and

$$\hat{\Phi}(1, 1) = \frac{1}{\sqrt{2}} \left( \begin{array}{c} |0\rangle + |eg\rangle \sin \tau \cos \tau \\ |e\rangle + |g\rangle \sin \tau \cos \tau \\ |e\rangle - |g\rangle \cos \tau \cos \tau \\ |0\rangle - |eg\rangle \cos \tau \sin \tau \end{array} \right)$$

$$\hat{\Phi}(1, 1) = \left( \begin{array}{c} \Phi_1 \\ \Phi_2 \\ \Phi_3 \\ \Phi_4 \end{array} \right)$$

(54)

Substituting Eq. (51) into Eq. (49) for the current, we get Eq. (44) for $\Delta_g = 0$.

**IX. APPENDIX B. UNITARY TRANSFORMATION FOR SUBSPACE (III) FOR INTERACTING ELECTRONS AT A SITE**

In the limit of strong Coulomb repulsion, the operator $Y^+(1, 1)$ is reduced to that defined by Eq. (35) in accordance with Eqs. (52), since the “hopping” operator $\hat{F}_j = (1)^j (\Delta_e / \sqrt{2}) (a_j^+ + a_j)$ has no nonzero matrix elements involving states with a single excitation $|e\rangle$ and $|g\rangle$ (see Appendix A). Substituting Eq. (55) into Eq. (49) for the current, we get Eq. (44) for $\Delta_g = 0$.

**X. APPENDIX C**

The steady-state solution of Eqs. (8), (27) in the RWA approximation gives for the case under consideration

$$\sigma(0, 0) = \sigma(0, 2) = \sigma_{++}(0, 1) = \sigma_{+-}(0, 1) = \sigma_{--}(0, 1) = 0$$

and $\sigma_{-+}(0, 1)$ and $\sigma(2, 0)$ are arbitrary. Putting $\sigma_{-+}(0, 1) = \sigma(2, 0) = 0$, we get

$$\sigma_{-+}(1, 0) = \frac{i\hbar}{8\Delta_e} \{ \Gamma_{M,1g} T \sigma(1, 0) + \Gamma_{M,2g} T \sigma(1, 1) \}$$

(56)

and $T \sigma(1, 0) = (\Gamma_{M,2g} / \Gamma_{M,1g}) T \sigma(1, 1)$. Then using the normalization condition

$$T \sigma(1, 0) + T \sigma(1, 1) = 1$$

(57)

and Eq. (36), we obtain Eq. (40) of Sec. 11.
