Minimax Policy for Heavy-tailed Multi-armed Bandits

Lai Wei
Vaibhav Srivastava

Abstract—We study the stochastic Multi-Armed Bandit (MAB) problem under worst case regret and heavy-tailed reward distribution. We modify the minimax policy MOSS [1] for the sub-Gaussian reward distribution by using saturated empirical mean to design a new algorithm called Robust MOSS. We show that if the moment of order $1 + \epsilon$ for the reward distribution exists, then the refined strategy has a worst-case regret matching the lower bound while maintaining a distribution dependent logarithm regret.

I. INTRODUCTION

The dilemma of exploration versus exploitation is common in scenarios involving decision-making in unknown environments. In these contexts, exploration means learning the environment while exploitation means taking empirically computed best actions. When finite time performance is concerned, i.e., scenarios in which one cannot learn indefinitely, ensuring a good balance of exploration and exploitation is the key to a good performance. Multi-armed bandit and its variations are prototypical models for these problems, and they are broadly applied in many areas such as economics, communication systems, and robotics.

The stochastic MAB problem was originally proposed by Robbins [2]. In this problem, an agent chooses an arm from a set of $K$ arms and receives a reward associated with the arm at each time slot. The reward at each arm is a stationary random variable with unknown mean reward. The objective is to design a policy that maximizes the cumulative reward or equivalently minimizes the expected cumulative regret, defined by the difference between the expected cumulative reward obtained by selecting the arm with the maximum mean reward at each time and selecting arms determined by the designed policy.

The notion of expected cumulative regret can be generalized to the worst-case regret, which is defined by the supremum of the expected cumulative regret computed over all possible reward distributions within a certain class such as distributions with bounded support, or sub-Gaussian distributions. The minimax regret is defined as the minimum worst case regret, where the minimum is computed over all the policies. By construction, the worst-case regret uses minimal information about the underlying distribution and the associated regret bounds are called distribution free bounds. In contrast, the standard regret bounds depend on the difference between the mean rewards associated with the optimal arm and suboptimal arms, and the corresponding bounds are referred as distribution-dependent bounds.

In their seminal work, Lai and Robbins [3] establish that the expected cumulative regret admits an asymptotic distribution dependent lower bound that is a logarithmic function of the time-horizon $T$. Here, asymptotic refers to the limit $T \to +\infty$. They also propose a general method of constructing Upper Confidence Bound (UCB) based policies that attain the lower bound asymptotically. By assuming rewards to be bounded or more generally sub-Gaussian, several subsequent works design simpler algorithms with finite time performance guarantees, e.g., the UCB1 algorithm by Auer et al. [4]. By using Kullback-Leibler(KL) divergence based upper confidence bounds, Garivier and Cappé [5] designed KL-UCB, which is proved to have efficient finite time performance as well as asymptotic optimality.

In the worst-case setting, the lower bound and upper bounds are distribution free bounds. Assuming the rewards are bounded, Audibert and Bubeck [1] establish a $\Omega(\sqrt{KT})$ lower bound on the minimax regret. They also studied a modified UCB algorithm called Minimax Optimal Strategy in the Stochastic case (MOSS) and proved that it achieves an order-optimal worst case regret while maintaining a logarithm distribution-dependent regret. Degene and Perchet [6] extend MOSS to an any-time version called MOSS-anytime.

The rewards being bounded or sub-Gaussian is a common assumption that gives sample mean an exponential convergence and simplifies the MAB problem. However in many applications, such as social networks [7] and financial markets [8], the rewards are heavy-tailed. For the standard stochastic MAB problem, Bubeck et al. [9] relax the sub-Gaussian assumption by only assuming the rewards to have finite moments of order $1 + \epsilon$ for some $\epsilon \in (0, 1]$. They present the robust UCB algorithm and show that it attains an upper bound on the cumulative regret that is within a constant factor of the distribution depend lower bound in the heavy-tailed setting. However, to the best of our knowledge, so far in the literature there is a lack of an algorithm that provably achieves an order optimal worst case regret for heavy-tailed bandits. A polylogarithmic extra factor exists in the solutions provided in [9].

In this paper, we study the minimax heavy tail bandit problem. We propose and analyze Robust MOSS algorithm and show that if the reward distributions admit moments of order $1 + \epsilon$, with $\epsilon > 0$, then it achieves minimax regret matching the lower bound while maintaining a distribution dependent logarithm regret. Our results builds on techniques in [1] and [9], and augment them with new analysis based on maximal Bennett inequalities.

The remaining paper is organized as follows. We describe the minimax heavy-tailed multiarmed bandit problem and present some background material in Section II. We present

and analyze the Robust MOSS algorithm in Sections III and IV respectively. Our conclusions are presented in Section V.

II. BACKGROUND & PROBLEM DESCRIPTION

A. Stochastic MAB Problem

In a stochastic MAB problem, an agent chooses an arm $\varphi_i$ from the set of $K$ arms $\{1, \ldots, K\}$ at each time $t \in \{1, \ldots, T\}$ and receives the associated reward. The reward at each arm $k$ is drawn from an unknown distribution $f_k$ with unknown mean $\mu_k$. Let the maximum mean reward among all arms be $\mu^*$. We use $\Delta_k = \mu^* - \mu_k$ to measure the suboptimality of arm $k$. The objective is to maximize the expected cumulative reward or equivalently to minimize the expected cumulative regret defined by

$$ R_T := \mathbb{E} \left[ \sum_{t=1}^{T} (\mu^* - X_{\varphi_t}) \right] = \mathbb{E} \left[ \sum_{t=1}^{T} \Delta_{\varphi_t} \right], $$

which is the difference between the expected cumulative reward obtained by selecting the arm with the maximum mean reward $\mu^*$ and selecting arms $\varphi_1, \ldots, \varphi_T$.

The expected cumulative regret $R_T$ is implicitly defined for a fixed distribution of rewards from each arm $\{f_1, \ldots, f_K\}$. The worst case regret is the expected cumulative regret for the worst possible choice of reward distributions $\{f_1, \ldots, f_K\}$. In particular,

$$ R_T^{\text{wors}} = \sup_{\{f_1, \ldots, f_K\}} R_T. $$

The regret associated with the policy that minimizes the above worst case regret is called minimax regret.

B. Problem Description: Heavy-tailed Stochastic MAB

In this paper, we study the heavy-tailed stochastic MAB problem, which is the stochastic MAB problem with following assumptions.

Assumption 1: Let $X$ be a random reward drawn from any arm $k \in \{1, \ldots, K\}$. There exists a constant $u \in \mathbb{R}_{>0}$ such that $\mathbb{E} \left[ |X|^{1+\epsilon} \right] \leq u^{1+\epsilon}$ for some $\epsilon \in (0, 1]$.

Assumption 2: Parameters $T, K, u$ and $\epsilon$ are known.

C. MOSS Algorithm for Worst-Case Regret

We now present the MOSS algorithm proposed in [1]. The MOSS algorithm is designed for stochastic MAB problem with bounded rewards and in this paper, we extend it to design Robust MOSS algorithm for heavy-tailed bandits.

Suppose that arm $k$ is sampled $n_k(t)$ times until time $t - 1$, and $\hat{\mu}_{n_k(t)}$ is the associated empirical mean, then, at time $t$, MOSS picks the arm that maximizes the following UCB

$$ g_{n_k(t)}^k = \hat{\mu}_{n_k(t)}^k + \sqrt{\frac{\ln \left( \frac{\sqrt{T}}{K n_k(t)} \right)}{n_k(t)}}, $$

If the rewards from the arms have bounded support $[0, 1]$, then the worst-case regret for MOSS satisfies $R_T^{\text{wors}} \leq 49\sqrt{KT}$, which is order optimal [1]. Meanwhile, MOSS maintains a logarithm distribution-dependent regret bound.

D. A Lower Bound for Heavy-tailed Minimax Regret

We now present the lower bound on the minimax regret for the heavy tailed bandit problem derived in [9].

Theorem 1 ( [9, Th. 2]): For any fixed time horizon $T$ and the stochastic MAB problem under Assumptions 1 and 2 with $u = 1$,

$$ R_T^{\text{wors}} \geq 0.01 K \frac{1}{\epsilon^3} T^{1+\epsilon}. $$

Remark 1: Since $R_T$ scales with $u$, the lower bound for heavy tail bandit is $\Omega(u K \frac{1}{\epsilon^3} T^{1+\epsilon})$. This lower bound also indicates that within a finite horizon $T$, it is almost impossible to differentiate the optimal arm from arm $k$; if $\Delta_k \in O(u (K/T)^{1+\epsilon})$.

III. A ROBUST MINIMAX POLICY

To deal with the heavy-tailed reward distribution, we replace the empirical mean with a saturated empirical mean. Although saturated empirical mean is a biased estimator, it has better convergence properties. We construct a novel UCB index to evaluate the arms, and at each time slot the arm with the maximum UCB is picked.

A. Robust MOSS

In Robust MOSS, we consider a robust mean estimator called saturated empirical mean which is formally defined in the following subsection. Let $n_k(t)$ be the number of times that arm $k$ has been selected until time $t - 1$. At time $t$, let $\hat{\mu}_{n_k(t)}^k$ be the saturated empirical mean reward computed from the $n_k(t)$ samples at arm $k$. Robust MOSS initializes by selecting each arm once and subsequently, at each time $t$, selects the arm that maximizes the following UCB

$$ g_{n_k(t)}^k = \hat{\mu}_{n_k(t)}^k + (1 + \eta) \epsilon_{n_k(t)}, $$

where $\eta > 0$ is an appropriate constant, $\epsilon_{n_k(t)} = u \times |\phi(n_k(t))| \frac{1}{\epsilon^3}$ and

$$ \phi(n) = \frac{\ln \left( \frac{\sqrt{T}}{K n} \right)}{n}, $$

where $\ln_+(x) := \max(\ln(x), 1)$.

B. Saturated Empirical Mean

The robust saturated empirical mean is similar to the truncated empirical mean used in [9], which is employed to extend UCB1 to achieve logarithm distribution dependent regret for the heavy-tailed MAB problem. Let $\{X_i\}_{i \in \{1, \ldots, m\}}$ be a sequence of i.i.d. random variables with mean $\mu$ and $\mathbb{E} \left[ |X_i|^{1+\epsilon} \right] \leq u^{1+\epsilon}$, where $u > 0$. Pick $\alpha > 1$ and let $h(m) = \alpha \log_+ (m) + 1$. Define the saturation point $B_m$ by

$$ B_m := u \times \left[ \phi(h(m)) \right]^{-\frac{1}{1+\epsilon}}, $$

Then, the saturated empirical mean estimator is defined by

$$ \hat{\mu}_m := \frac{1}{m} \sum_{i=1}^{m} \text{sat}(X_i, B_m), $$

(1)

where $\text{sat}(X_i, B_m) := \text{sign}(X_i) \min \{|X_i|, B_m\}$. Define $d_i := \text{sat}(X_i, B_m) - \mathbb{E} [\text{sat}(X_i, B_m)]$. The following lemma examines the estimator bias and provides an upper bound on the error of saturated empirical mean.
Lemma 2 (Error of saturated empirical mean): For an i.i.d. sequence of random variables \( \{X_i\}_{i \in \{1, \ldots, m\}} \) such that \( \mathbb{E}[X_i] = \mu \) and \( \mathbb{E}[X_i^{1+\epsilon}] \leq u^{1+\epsilon} \), the saturated empirical mean \( \hat{\mu}_m \) satisfies

\[
|\hat{\mu}_m - \mu - \frac{1}{m} \sum_{i=1}^{m} d_i| \leq \frac{u^{1+\epsilon}}{B_m^\epsilon}.
\]

Proof: Since \( \mu = \mathbb{E}[X_i(1{\{X_i \leq B_m\}} + 1{\{X_i > B_m\}})] \), the error of estimator \( \hat{\mu}_m \) satisfies

\[
|\hat{\mu}_m - \mu| = \frac{1}{m} \sum_{i=1}^{m} (\text{sat}(X_i, B_m) - \mu) = \frac{1}{m} \sum_{i=1}^{m} d_i + \frac{1}{m} \sum_{i=1}^{m} (\mathbb{E}[\text{sat}(X_i, B_m)] - \mu),
\]
where the second term is the bias of \( \hat{\mu}_m \). We now compute an upper bound on the bias.

\[
\mathbb{E}[\text{sat}(X_i, B_m)] - \mu \leq \mathbb{E}[X_i(1{\{X_i > B_m\}})] 
\leq \mathbb{E}[X_i^{1+\epsilon}/(B_m^\epsilon)] = \frac{u^{1+\epsilon}}{(B_m^\epsilon)},
\]

which concludes the proof.

Now we establish properties of \( d_i \).

Lemma 3 (Properties of \( d_i \)): For any \( i \in \{1, \ldots, m\} \), \( d_i \) satisfies (i) \( |d_i| \leq 2B_m \) (ii) \( \mathbb{E}[d_i^2] \leq u^{1+\epsilon}B_m^{1-\epsilon} \).

Proof: Property (i) follows immediately from definition of \( d_i \), and property (ii) follows from

\[
\mathbb{E}[d_i^2] \leq \mathbb{E}[\text{sat}^2(X_i, B_m)] \leq \mathbb{E}[X_i^{1+\epsilon}B_m^{1-\epsilon}].
\]

IV. ANALYSIS OF ROBUST MOSS

In this section, we analyze Robust MOSS to provide both distribution-free and distribution-dependent regret bounds.

A. Properties of Saturated Empirical Mean Estimator

To derive the concentration property of saturated empirical mean, we use a maximal Bennett type inequality as shown in Lemma 4.

Lemma 4 (Maximal Bennett’s inequality [10]): Let \( \{X_i\}_{i \in \{1, \ldots, n\}} \) be a sequence of bounded random variables with support \([-B, B]\), where \( B \geq 0 \). Suppose that \( \mathbb{E}[X_i | X_1, \ldots, X_{i-1}] = \mu_i \) and \( \text{Var}[X_i | X_1, \ldots, X_{i-1}] \leq u \). Let \( S_m = \sum_{i=1}^{m} (X_i - \mu_i) \) for any \( m \in \{1, \ldots, n\} \). Then, for any \( \delta \geq 0 \)

\[
P(\exists m \in \{1, \ldots, n\} : S_m \geq \delta) \leq \exp \left( -\frac{\delta}{B} \psi \left( \frac{B\delta}{nu} \right) \right),
\]

\[
P(\exists m \in \{1, \ldots, n\} : S_m \leq -\delta) \leq \exp \left( -\frac{\delta}{B} \psi \left( \frac{B\delta}{nu} \right) \right),
\]

where \( \psi(x) = (1 + 1/x) \ln(1 + x) - 1 \).

Remark 2: For \( x \in (0, \infty) \), function \( \psi(x) \) is monotonically increasing in \( x \).

Now, we establish an upper bound on the probability that the UCB underestimates the mean at arm \( k \) by an amount \( x \).

Lemma 5: For any arm \( k \in \{1, \ldots, K\} \) and any \( t \in \{K + 1, \ldots, T\} \) and \( x > 0 \), if \( \eta \psi(\eta/a) \geq 2a \), the probability of event \( \{g_{n_k(t)}^k \leq \mu_k - x\} \) is no greater than

\[
\frac{K}{T} a \ln(a) \Gamma \left( \frac{1}{c} + 2 \right) \left( \psi \left( \frac{2\eta/a}{x} \right) - \frac{1}{x} \right).
\]

Proof: It follows from Lemma 2 that

\[
P \left( g_{n_k(t)}^k \leq \mu_k - x \right) \leq \mathbb{P} \left( \exists m \in \{1, \ldots, T\} : \hat{\mu}_m^k + (1 + \eta) c_m \leq \mu_k - x \right)
\leq \mathbb{P} \left( \exists m \in \{1, \ldots, T\} : \sum_{i=1}^{m} \frac{d_i^k}{m} \leq \frac{u^{1+\epsilon}}{B_m^\epsilon} - (1 + \eta) c_m - x \right)
\leq \mathbb{P} \left( \exists m \in \{1, \ldots, T\} : \sum_{i=1}^{m} d_i^k \leq -x - \eta c_m \right),
\]

where \( d_i^k \) is defined similarly to \( d_i \) for i.i.d. reward sequence at arm \( k \) and the last inequality is due to

\[
\frac{u^{1+\epsilon}}{B_m^\epsilon} = u \left[ \phi(h(m)) \right]^{1+\epsilon} \leq u \left[ \phi(m) \right]^{1+\epsilon} = c_m.
\]

Recall \( a > 1 \). We apply a peeling argument [11, Sec 2.2] with geometric grid \( a^s \leq m < a^{s+1} \) over time interval \{1, \ldots, T\}. Since \( c_m \) is monotonically decreasing with \( m \),

\[
P \left( \exists m \in \{1, \ldots, T\} : \frac{1}{m} \sum_{i=1}^{m} d_i^k \leq -x - \eta c_m \right)
\leq \sum_{a > 0} \mathbb{P} \left( \exists m \in [a^s, a^{s+1}) : \sum_{i=1}^{m} d_i^k \leq -a^s (x + \eta c_{a^{s+1}}) \right).
\]

Also notice that \( B_m = B_{a^s} \) for all \( m \in [a^s, a^{s+1}) \). Then with properties in Lemma 3, we apply Lemma 4 to get

\[
\sum_{s > 0} \mathbb{P} \left( \exists m \in [a^s, a^{s+1}) : \sum_{i=1}^{m} d_i^k \leq -a^s (x + \eta c_{a^{s+1}}) \right)
\leq \sum_{s > 0} \exp \left( -a^s (x + \eta c_{a^{s+1}}) \psi \left( \frac{2B_{a^s}}{2B_{a^{s+1}}} (x + \eta c_{a^{s+1}}) \right) \right)
\text{ (since } \psi(x) \text{ is monotonically increasing)}
\leq \sum_{s > 0} \exp \left( -a^s (x + \eta c_{a^{s+1}}) \psi \left( \frac{2B_{a^{s+1}}}{2B_{a^s}} c_{a^{s+1}} \right) \right)
\text{ (substituting } c_{a^{s+1}}, B_{a^{s+1}} \text{ and using } h(a^s) = a^{s+1})
\begin{align*}
&= \sum_{s > 1} \exp \left( -a^s \left( \frac{x}{B_{a^{s-1}}} + \eta \phi(a^s) \right) \psi \left( \frac{2\eta/a}{2a} \right) \right)
&\text{ (since } \psi(2\eta/a) \geq 2a)\\
&\leq \frac{K}{T} \sum_{s \geq 1} a^s \exp \left( -a^s \left( \frac{x}{B_{a^{s-1}}} \right) \psi \left( \frac{2\eta/a}{2a} \right) \right).
\end{align*}

(3)
Let \( b = x \psi (2 \eta /a) / (2a\mu) \). Since \( \ln_+ (x) \geq 1 \) for all \( x > 0 \),

\[
(3) \leq \frac{K}{T} \sum_{s \geq 1} a^s \exp \left( -b \frac{t}{\Gamma(\frac{1}{a})} \right) \\
\leq \frac{K}{T} \int_1^{+\infty} a^y \exp \left( -ba \frac{y}{\Gamma(\frac{1}{a})} \right) dy \\
= \frac{K}{T} a \int_0^{+\infty} a^y \exp \left( -ba \frac{y}{\Gamma(\frac{1}{a})} \right) dy \\
\quad \text{where we set } z = ba \frac{y}{\Gamma(\frac{1}{a})} \\
= \frac{K}{T} a \frac{1}{\Gamma(\frac{1}{a})} b^{-\frac{1}{a}} \int_{b}^{+\infty} z^{1-a} \exp (-z) dz \\
\leq \frac{K}{T} \frac{1}{\Gamma(\frac{1}{a})} \Gamma \left( \frac{1}{a} + 2 \right) b^{-\frac{1}{a}} 
\]

which conclude the proof.

The following is a straightforward corollary of Lemma \( [5] \).

**Corollary 6:** For any arm \( k \in \{1, \ldots, K\} \) and any \( t \in \{K + 1, \ldots, T\} \) and \( x > 0 \), if \( \eta \psi(2\eta/a) \geq 2a \), the probability of event \( \{g_{n_k(t)} - 2(1 + \eta)c_{n_k(t)} \geq \mu_k + x\} \) shares the same bound in Lemma \( [5] \).

**B. Distribution Free Regret Bound**

The distribution free upper bound for Robust MOSS, which is the main result for the paper, is presented in this section. We show that the algorithm achieves order optimal worst case regret.

**Theorem 7:** For the heavy-tailed stochastic MAB problem with \( K \) arms and time horizon \( T \), if \( \eta \) and \( a \) are selected such that \( \eta \psi(2a) \geq 2a \), then Robust MOSS satisfies

\[
R_T^{\text{regret}} \leq C u K \frac{T}{\epsilon} + 2a K, 
\]

where \( C = \Gamma \left( \frac{1}{a} + 2 \right) \left[ a / (6 + 3\eta) \right] \frac{1}{a} + c \Gamma \left( \frac{1}{\epsilon} + 2 \right) \left( 6 + 3\eta \right) \left[ 6a / \psi(2\eta/a) \right] \frac{1}{a} + a / \ln(a) + (6 + 3\eta) \left[ c + (1 + e) \right] \frac{1}{\Gamma(\frac{1}{a})} \]

**Proof:** Since both UCB and regret scales with \( u \) defined in Assumption \( [1] \) to simplify the expressions, we assume \( u = 1 \). Also notice Assumption \( [1] \) indicates \( |\mu_k| \leq u \), so \( \Delta_k \leq 2 \) for any \( k \in \{1, \ldots, K\} \). Furthermore, any terms with superscript or subscript “*” and “k” are with respect to the best and the \( k \)-th arm, respectively. The proof is divided into 4 steps.

**Step 1:** We follow a decoupling technique inspired by the proof of regret upper bound in MOSS [1]. Take the set of \( \delta \)-bad arms as \( B_\delta \) as

\[
B_\delta := \{ k \in \{1, \ldots, K\} | \Delta_k > \delta \}, \tag{4}
\]

where we assign \( \delta = (6 + 3\eta) (e\mu /T) \frac{1}{\Gamma(\frac{1}{a})} \). Thus,

\[
R_T \leq T \delta + \sum_{k=1}^{K} \Delta_k + E \left[ \sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta \} (\Delta_\varphi_t - \delta) \right] \\
\leq T \delta + 2K + E \left[ \sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta \} (\Delta_\varphi_t - \delta) \right]. \tag{5}
\]

Furthermore, we make the following decomposition

\[
\sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta \} (\Delta_\varphi_t - \delta) \\
\leq \sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta, g^*_{n(t)} \leq \mu^* - \Delta_\varphi_t / 3 \} (\Delta_\varphi_t - \delta) \tag{6} \]

\[
+ \sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta, g^*_{n(t)} > \mu^* - \Delta_\varphi_t / 3 \} (\Delta_\varphi_t - \delta). 
\]

Notice that \( (6) \) describes regret from underestimating optimal arm \( * \). For the second summand, since \( g^*_{n(t)} \geq g^*_{n(t)} \),

\[
\sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta, g^*_{n(t)} > \mu^* - \Delta_\varphi_t / 3 \} (\Delta_\varphi_t - \delta) \\
\leq \sum_{t=K+1}^{T} I \{ \varphi_t \in B_\delta, g^*_{n(t)} > \mu^* - \Delta_\varphi_t / 3 \} (\Delta_\varphi_t - \delta) \\
= \sum_{k=1}^{K} \sum_{t=K+1}^{T} I \{ \varphi_t = k, \varphi_k^* (t) / \mu_k + \Delta_\varphi / 3 \} (\Delta_\varphi, \delta), \tag{7}
\]

which characterizes the regret caused by overestimating \( \delta \)-bad arms.

**Step 2:** In this step, we bound the expectation of \( (6) \). When event \( \{ \varphi_t \in B_\delta, g^*_{n(t)} \leq \mu^* - \Delta_\varphi_t / 3 \} \) happens, we know

\[
\Delta_\varphi \leq 3\mu^* - 3g^*_{n(t)} \text{ and } g^*_{n(t)} < \mu^* - \delta / 3.
\]

Thus, we get

\[
I \{ \varphi_t \in B_\delta, g^*_{n(t)} \leq \mu^* - \Delta_\varphi_t / 3 \} (\Delta_\varphi_t - \delta) \\
\leq I \{ \varphi_t \in B_\delta, g^*_{n(t)} \leq \mu^* - \delta / 3 \} \times (3\mu^* - 3g^*_{n(t)} - \delta) := Y_t
\]

Since \( Y_t \) is a positive random variable, its expected value can be computed involving only its cumulative density function:

\[
E \{ Y_t \} = \int_0^{+\infty} P (Y_t > x) dx \\
\leq \int_0^{+\infty} P (3\mu^* - 3g^*_{n(t)} - \delta > x) dx \\
= \int_{\delta}^{+\infty} P (\mu^* - 3g^*_{n(t)} > x) dx.
\]

Then we apply Lemma \( [5] \) at optimal arm \( * \) to get

\[
E \{ Y_t \} \leq \frac{KC_1}{T} \int_{\delta}^{+\infty} \frac{1}{\epsilon} x^{1-1} dx = \frac{KC_1}{T\delta} 
\]

where \( C_1 = e \Gamma (1/\epsilon + 2) [6a/\psi(2\eta/a)]^{1-1} a / \ln(a) \). We conclude this step by

\[
E \{ (6) \} \leq \sum_{t=K+1}^{T} Y_t \leq C_1 K \delta^{-\frac{1}{2}}.
\]
Step 3: In this step, we bound the expectation of (7). For each arm $k \in \mathcal{B}_\delta$, 
$$
\sum_{t=m+1}^{T} 1 \left\{ \varphi_t = k, n_k(t) \geq \mu_k + \frac{2D_k}{3} \right\}
$$
$$= \sum_{t=m+1}^{T} \sum_{i=1}^{m} \left\{ \varphi_t = k, n_k(t) = m \right\} \left\{ g_k \geq \mu_k + \frac{2D_k}{3} \right\}
$$
$$\leq \sum_{t=m+1}^{T} \sum_{i=1}^{m} \left\{ \varphi_t = k, n_k(t) = m \right\}
$$
$$\leq \sum_{t=m+1}^{T} \left\{ g_k \geq \mu_k + \frac{2D_k}{3} \right\}
$$
$$\leq \sum_{m=1}^{T} \left\{ g_k \geq \mu_k + \frac{2D_k}{3} \right\}
$$
where in the last inequality we apply Lemma 2.

Let $\beta = a^{\frac{-1}{1+\epsilon}} \psi(6 + 3\eta) \Delta_k / 3$. Then we have
$$
E[|\tilde{R} - \Delta_k|] \leq \int_{0}^{\infty} \exp \left( -\beta y^{\frac{1}{1+\epsilon}} \right) dy
$$
$$= \frac{1+\epsilon}{\epsilon} \beta^{-\frac{1}{1+\epsilon}} \int_{0}^{\infty} z^{\frac{1}{1+\epsilon}} \exp(-z) dy
$$
$$= \Gamma \left( \frac{1}{\epsilon} + 2 \right) \beta^{-\frac{1}{1+\epsilon}}.
$$
Plugging it into (10),
$$
E[8] \leq C_2 \Delta_k^{-\frac{1}{1+\epsilon}} + C_3 \Delta_k^{-\frac{1}{1+\epsilon}} \ln \left( \frac{T}{K C_3} \right)
$$
where $C_2 = \Gamma (1/\epsilon + 2) a^\frac{1}{\epsilon} [3/\psi(6 + 3\eta)]^{\frac{1+\epsilon}{2}}$ and $C_3 = (6 + 3\eta)^{\frac{1+\epsilon}{2}}$. Put it together with $\Delta_k \geq \delta$ for all $k \in \mathcal{B}_\delta$.

Step 4: Plugging the results in step 2 and step 3 into (5),
$$
R_T \leq T \delta + [C_1 + C_2 (1 + \epsilon) \epsilon^{\frac{1}{1+\epsilon}} C_3 \delta^{-\frac{1}{2}} + 2K].
$$
Straightforward calculation concludes the proof. 

C. Distribution Dependent Regret Upper Bound

We now show that robust MOSS also preserves a logarithm upper bound on the distribution dependent regret.

Theorem 8: For the heavy-tailed stochastic MAB problem with $K$ arms and time horizon $T$, if $\eta \psi(2\eta/a) \geq 2a$, the regret $R_T$ for Robust Moss is no greater than
$$
\sum_{k: \Delta_k \geq \delta} \left( \frac{u^{1+\epsilon}}{\Delta_k} \right)^{\frac{1}{1+\epsilon}} \left[ \frac{C_1 \ln \left( \frac{T}{K C_1} \left( \frac{\Delta_k}{u} \right)^{\frac{1+\epsilon}{2}} \right) + C_2 K}{\Delta_k} \right] + \Delta_k,
$$
where $C_1 = \left( 4 + 4\eta \right)^{\frac{1+\epsilon}{2}}$ and $C_2 = \max \{ \epsilon C_1, 2(1/\epsilon) \left( \frac{8a}{\psi(2\eta/a)} \right)^{\frac{1+\epsilon}{2}} a / \ln(a) \}$. 

Proof: Let $\delta = (4 + 4\eta) \left( eK / T^{\frac{1}{1+\epsilon}} \right)$ define $B_\delta$ the same as (4). Since $\Delta_k \leq \delta$ for all $k \notin \mathcal{B}_\delta$, the regret satisfies
$$
R_T \leq \sum_{k \in \mathcal{B}_\delta} T \Delta_k + \sum_{t=1}^{T} \left\{ \varphi_t \in \mathcal{B}_\delta \right\} \Delta_{\varphi_t}
$$
$$\leq \sum_{k \notin \mathcal{B}_\delta} eK \left( \frac{4 + 4\eta}{\Delta_k} \right)^{\frac{1+\epsilon}{2}} \Delta_k + \sum_{t=1}^{T} \left\{ \varphi_t = k \right\} \Delta_k
$$
$$\leq \sum_{t=1}^{T} \left\{ \varphi_t = k \right\} \Delta_k.
$$
Pick arbitrary $l_k \in \mathbb{Z}_+$, thus
$$
\sum_{t=1}^{T} \left\{ \varphi_t = k \right\} \leq l_k + \sum_{t=K+1}^{T} \left\{ \varphi_t = k, n_k(t) \geq l_k \right\}
$$
$$\leq l_k + \sum_{t=K+1}^{T} \left\{ g^*_k \geq n^*_k(t), n_k(t) \geq l_k \right\}.
$$
Observe that $g_{n_k(t)}^k \geq g_n^*(t)$ implies at least one of the following is true

$$
g_n^*(t) \leq \mu^* - \frac{\Delta_k}{4}, \quad (13)$$

$$
g_k(t) \geq \mu_k + \frac{\Delta_k}{4} + 2(1 + \eta)c_{n_k(t)}, \quad (14)$$

$$(1 + \eta)c_{n_k(t)} > \frac{\Delta_k}{4}. \quad (15)$$

We select

$$
l_k = \left[ \left( \frac{4 + 4\eta}{\Delta_k} \right)^{\frac{1+\epsilon}{1+\eta}} \ln \left( \frac{T}{K} \left( \frac{\Delta_k}{4 + 4\eta} \right)^{\frac{1+\epsilon}{1+\eta}} \right) \right]. \quad (16)$$

Similarly as (12), $n_k(t) \geq l_k$ indicates $c_{n_k(t)} \leq \Delta_k/(4 + 4\eta)$, so (15) is false. Then we apply Lemma 5 and Corollary 6

$$
\mathbb{P}\left\{ g_{n_k(t)} \geq g_n^*(t), n_k(t) \geq l_k \right\} \leq \mathbb{P}(13) \text{ or (14) is true } \leq \frac{C_2'K}{T} \Delta_k^{-\frac{1+\epsilon}{1+\eta}},
$$

where $C_2' = 2\Gamma(1/\epsilon + 2) \left( 8a/\psi(2\eta/a) \right)^{\frac{1+\epsilon}{1+\eta}} a/\ln(a)$. Substituting it into (12), $R_T$ is upper bounded by

$$
\sum_{k \notin B_k} \frac{tC_1K}{\Delta_k^\frac{1+\epsilon}{1+\eta}} + \sum_{k \in B_k} \left[ \frac{C_1}{\Delta_k^\frac{1+\epsilon}{1+\eta}} \ln \left( \frac{T}{K} \frac{\Delta_k^\frac{1+\epsilon}{1+\eta}}{C_1} \right) + \frac{C_1'K}{\Delta_k^\frac{1+\epsilon}{1+\eta}} + \Delta_k \right].
$$

Considering the scaling factor $u$, the proof can be concluded with easy computation.

V. NUMERICAL ILLUSTRATION

In this section, we compare the simulation results for Robust MOSS and MOSS in a 3-armed heavy-tailed bandit. The mean rewards are $\mu_1 = -0.3$, $\mu_2 = 0$ and $\mu_3 = 0.3$ and sampling at each arm $k$ returns a random reward equals to $\mu_k$ added by sampling noise $\nu$, where $|\nu|$ is a generalized Pareto random variable and the sign of $\nu$ has equal probability to be positive and negative. The probability density function of reward at arm $k$ is

$$
f_k(x) = \frac{1}{2\sigma} \left( 1 + \frac{\xi |x - \mu_k|}{\sigma} \right)^{-\frac{1}{\xi}} \text{ for } x \in (-\infty, +\infty),
$$

where we select $\xi = 0.33$ and $\sigma = 0.32$. Thus, for a random reward $X$ from any arm, we know $\mathbb{E}[X^2] \leq 1$, which means $\epsilon = 1$ and $u = 1$. We select parameters $\alpha = 1.1$ and $\eta = 2.2$ for Robust MOSS so that condition $\eta\psi(2\eta/a) \geq 2a$ is met.

Fig. 1 shows the mean cumulative regret together with quantiles of cumulative regret distribution as a function of time. The mean and quantiles are computed using 200 simulations of each policy. The simulation result shows that there is a chance MOSS loses stability in heavy-tailed MAB and suffers linear cumulative regret while Robust MOSS works consistently and maintains sub-linear cumulative regret.

VI. CONCLUSIONS AND FUTURE DIRECTIONS

We proposed the Robust MOSS algorithm for heavy-tailed bandit problem. We evaluate the algorithm by deriving upper bounds on the associated distribution-free and distribution-dependent regrets. Our analysis shows that Robust MOSS achieves order optimal performance in both scenarios.

There are several possible future directions. The saturated mean estimator centers at zero which make the algorithm not translation invariant. Exploration of translation invariant robust mean estimator in this context remains an open problem. The upper bound derived for Robust MOSS has a leading constant that contains gamma function of $1/\epsilon + 2$ which does not exist in the lower bound. It is an open problem to close this gap.
