Expression of the AHPND Toxins PirA\textsuperscript{vp} and PirB\textsuperscript{vp} Is Regulated by Components of the Vibrio parahaemolyticus Quorum Sensing (QS) System

Shin-Jen Lin \textsuperscript{1}, Jiun-Yan Huang \textsuperscript{1,†}, Phuoc-Thien Le \textsuperscript{2,3,†}, Chung-Te Lee \textsuperscript{1}, Che-Chang Chang \textsuperscript{2,4}, Yi-Yuan Yang \textsuperscript{5,6,†}, Emily Chia-Yu Su \textsuperscript{7}, Chu-Fang Lo \textsuperscript{1,†} and Hao-Ching Wang \textsuperscript{1,2,4,†}

Abstract: Acute hepatopancreatic necrosis disease (AHPND) in shrimp is caused by Vibrio strains that harbor a pVA1-like plasmid containing the pirA and pirB genes. It is also known that the production of the PirA and PirB proteins, which are the key factors that drive the observed symptoms of AHPND, can be influenced by environmental conditions and that this leads to changes in the virulence of the bacteria. However, to our knowledge, the mechanisms involved in regulating the expression of the pirA/pirB genes have not previously been investigated. In this study, we show that in the AHPND-causing Vibrio parahaemolyticus 3HP strain, the pirA\textsuperscript{vp} and pirB\textsuperscript{vp} genes are highly expressed in the early log phase of the growth curve. Subsequently, the expression of the PirA\textsuperscript{vp} and PirB\textsuperscript{vp} proteins continues throughout the log phase. When we compared mutant strains with a deletion or substitution in two of the quorum sensing (QS) master regulators, luxO, and/or opaR, our results suggested that expression of the pirA\textsuperscript{vp} and pirB\textsuperscript{vp} genes was related to the QS system, with luxO acting as a negative regulator of pirA\textsuperscript{vp} and pirB\textsuperscript{vp} without any mediation by opaR\textsuperscript{vp}. The expression patterns of pirA\textsuperscript{vp} and pirB\textsuperscript{vp} were paralleled by EMSA showed that AphB\textsuperscript{vp} could bind to this predicted region, even though another QS transcriptional regulator, AphA, could not. Taken together, these findings suggest that the QS system may play a role in regulating the expression of the PirA and PirB proteins, which are the key factors that drive the observed symptoms of AHPND.

1. Introduction

*Vibrio parahaemolyticus* is an opportunistic marine pathogen often found in the ocean and estuary environment [1]. In general, *V. parahaemolyticus* is recognized as an etiologic agent that causes acute gastroenterocolitis and diarrhea after human consumption of contaminated seafood [2,3]. Consequently, most earlier studies were on the pathogenesis of *V. parahaemolyticus* in humans and focused on virulence factors such as its hemolysins, T3SSs, and T6SSs [4–6]. However, several strains of *V. parahaemolyticus* were also identified as causative agents of the newly emergent acute hepatopancreatic necrosis disease (AHPN) in shrimp [7]. Since the first outbreak in China in 2009, AHPN has rapidly spread across southeast Asia and reached as far as central and south America, leading to huge losses in the aquaculture industry [8–10]. AHPN induces early mortality, usually within 35 to 45 days after stocking post-larvae shrimp in cultivation ponds [11]. Characteristic AHPN symptoms in shrimp include a pale and atrophied hepatopancreas (HP) with an empty stomach and midgut [7,9]. Histological examination has further shown that AHPN causes sloughing of the HP tubule epithelial cells into the HP tubule lumens [7,9], and this has become the main diagnostic criterion to confirm an AHPN infection. AHPN-causing strains harbor a 70-kbp plasmid (pVA1) that produces the “Photorhabdus insect-related” (Pir)-like binary toxins, PirA<sup>vp</sup> and PirB<sup>vp</sup> [12]. These two AHPN-associated toxins form a complex that is structurally homologous to the insecticidal Cry toxin [12–14], and they have been confirmed as the key factors that drive AHPN pathogenesis [12]. However, while previous studies have increased our understanding of the structural and functional characteristics of PirA<sup>vp</sup> and PirB<sup>vp</sup>, the mechanism by which the PirA<sup>vp</sup> and PirB<sup>vp</sup> genes are regulated still remains unknown. Here, we investigate this mechanism and show that the quorum sensing (QS) system may play an important role.

QS is a cell density-dependent process that regulates the expression of a number of genes in both Gram-positive and Gram-negative bacteria [15]. The QS system achieves this regulation by a series of control factors, including LuxO, OpaR (a homolog of LuxR), and AphA [16,17]. QS-regulated genes are involved in many important physiological activities, such as biofilm formation, bioluminescence, virulence factor production, conjugation, plasmid transfer, antibiotic production, cell mobility, and sporulation [15]. The importance of the QS system in AHPN pathogenicity was also recently demonstrated: extract from *V. alginolyticus* BC25 contained the anti-QS compounds Cyclo-(L-Leu-L-Pro) and Cyclo-(Pir)-like binary toxins, PirA<sup>vp</sup> and PirB<sup>vp</sup> [12]. These two AHPN-associated toxins form a complex that is structurally homologous to the insecticidal Cry toxin [12–14], and they have been confirmed as the key factors that drive AHPN pathogenesis [12]. However, while previous studies have increased our understanding of the structural and functional characteristics of PirA<sup>vp</sup> and PirB<sup>vp</sup>, the mechanism by which the PirA<sup>vp</sup> and PirB<sup>vp</sup> genes are regulated still remains unknown. Here, we investigate this mechanism and show that the quorum sensing (QS) system may play an important role.

Here we show how LuxO<sup>vp</sup>, which is an important regulator of QS in *Vibrio* spp., affects the gene expression of the key AHPN pathogenic factors *pirA<sup>vp</sup>* and *pirB<sup>vp</sup>*. First, by monitoring the gene/protein expression of PirA<sup>vp</sup> and PirB<sup>vp</sup> during the growth of *V. parahaemolyticus*, we found the appearance of these two toxins is cell density-dependent. We then confirmed that, at the low cell density stage (LCD, OD<sub>600</sub> ≈ 0.6), the deletion of LuxO<sup>vp</sup> significantly increased the gene/protein expression of PirA<sup>vp</sup> and PirB<sup>vp</sup> in *V. parahaemolyticus*. Next, in a PirA<sup>vp</sup>/PirB<sup>vp</sup> operon analysis, a possible DNA binding site for the *Vibrio* regulator AphB was identified. AphB is known as an activator, which plays a central role in virulence gene expression in both *Vibrio cholerae* and *Vibrio alginolyticus* [19,20]. It also plays a regulatory role as a QS control factor of LuxR [20]. Here, using EMSA (electrophoretic mobility shift assay), we confirmed that *V. parahaemolyticus* AphB (AphB<sup>vp</sup>) bound to the proposed promoter region of the PirA<sup>vp</sup>/PirB<sup>vp</sup> operon. Using real-time polymerase chain reactions, we also found a correlation between the expression levels of LuxO<sup>vp</sup> and AphB<sup>vp</sup>. At low cell density, the expression of AphB<sup>vp</sup> was increased by 1.7 fold in LuxO<sup>vp</sup>-deleted *V. parahaemolyticus*, and this increase was positively correlated to the gene/protein expression of PirA<sup>vp</sup> and PirB<sup>vp</sup> under the same conditions. Taken together, our results show that the PirA<sup>vp</sup>/PirB<sup>vp</sup> genes are regulated by components of the QS system, particularly by AphB<sup>vp</sup>.
This is the first report to investigate the influence of the bacterial physiological system on the pirAvp/pirBvp genes. Our findings will be helpful for the development of APHND prevention and/or control strategies in the future.

2. Results

2.1. The Expression Levels of pirAvp/pirBvp during Different Growth Phases of V. parahaemolyticus

In Vibrio, since QS is involved in the regulation of many physiological processes, including several virulence-related systems, we first wanted to determine if the expression level of pirAvp/pirBvp was cell density-dependent. We, therefore, recorded the growth curve of the wild type V. parahaemolyticus, 3HP strain, and analyzed the gene expression patterns of pirAvp and pirBvp. As shown in Figure 1A, the lag phase lasted until about 3.5 h (OD600 from 0.01 to ~0.6), the log phase ran until 9 h (OD600 from 0.6 to ~7.7), and the stationary phase ran from 9–13 h (OD600 from 7.7 to ~8.8). The expression of pirAvp and pirBvp remained low until the curve entered the log phase (Figure 1B). Expression levels reached their peaks at 5 h, then declined again at 6 h and continued to remain low (Figure 1B). To determine the protein expression patterns, we used specific anti-PirA vp and anti-PirB vp antibodies to detect the PirA vp and PirB vp proteins at each time point. As shown in Figure 2, the PirA vp and PirB vp expression levels were low in the lag phase except for 1 h. The over-presence at this time point might be due to carry-over from 15 h culture prior to inoculation. The expression levels were high in the log phase through to the early part of the stationary phase (4–10 h), after which they returned to lower levels until the end of the recording.

Figure 1. Growth curve and pirAvp and pirBvp expression levels in V. parahaemolyticus strain 3HP. (A) V. parahaemolyticus strain 3HP was cultured in LB (2% NaCl), and the growth curve was recorded every hour until 13 h after inoculation. (B) Relative mRNA expression of pirAvp and pirBvp in the strain 3HP during different growth phases. Total RNA was extracted from V. parahaemolyticus 3HP collected at the indicated time points (OD600 0.01–8.82), and analyzed by real-time qPCR with specific primers for pirAvp and pirBvp, respectively. Expression levels are shown relative to those of the gyrB reference gene.
luxO with the previously [21]. Successful deletion in the different mutants was confirmed by using specific and amino acid of LuxO previously [21]. Successful deletion in the different mutants was confirmed by using the and strain 3HP. These mutants had a deletion in and luxO.

2.2. LuxO Is a Negative Regulator for the Expression of pirAvp and pirBvp

To better understand whether QS regulation is involved in the expression of pirAvp and pirBvp, isogenic mutants of opaR and luxO were derived from the AHPND-causing strain 3HP. These mutants had a deletion in opaR (ΔopaR) or luxO (ΔluxO), or in both opaR and luxO (ΔopaRΔluxO), and they were constructed by allelic gene exchange as described previously [21]. Successful deletion in the different mutants was confirmed by using opaR-specific and luxO-specific primer sets (Figure 3). In addition, we also mutated the 47th amino acid of LuxO from aspartic acid (D) to glutamic acid (E) to mimic the permanently active form of LuxOΔD (LuxOD47E). All mutants exhibited similar growth rates to that of the wild-type strain in LB+ medium (Figure S1). As shown in Figure 4, the gene expression levels of pirAΔD and pirBΔD were down-regulated to about 60% when the active form of LuxOΔD was mimicked, while the expression levels were up-regulated by about 2 folds with the luxOΔD deletion mutants (i.e., ΔluxO and ΔopaRΔluxO). By contrast, the opaRΔD deletion mutant had only a small, statistically insignificant effect on the expression of pirAΔD and pirBΔD, suggesting that although opaRΔD is one of the core regulators of the QS system, unlike luxOΔD, it plays only a minor role in the expression of pirAΔD and pirBΔD. Similar effects were also seen in the protein expression levels of PirAΔD and PirBΔD, although we note that, despite the reduction in mRNA expression, protein levels were not reduced by

---

**Figure 2.** Protein expression levels of endogenous PirAΔD and PirBΔD in *V. parahaemolyticus* wild type strain (3HP) during different growth phases. Cell lysate (2 µg) was separated, transferred onto a PVDF membrane, and reacted with (A) chicken anti-PirAΔD and (B) anti-PirBΔD polyclonal antibodies to recognize the endogenous PirAΔD and PirBΔD, respectively. (C) Loading control (8 µg/lane).

---

By contrast, the opaRΔD deletion mutant had only a small, statistically insignificant effect on the expression of pirAΔD and pirBΔD, suggesting that although opaRΔD is one of the core regulators of the QS system, unlike luxOΔD, it plays only a minor role in the expression of pirAΔD and pirBΔD. Similar effects were also seen in the protein expression levels of PirAΔD and PirBΔD, although we note that, despite the reduction in mRNA expression, protein levels were not reduced by
the \( \text{luxO}^{D7E} \) mimic (Figure 4A,B, upper panels). Taken together, these results suggest that the expression of \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \) is negatively regulated by \( \text{luxO}^{vp} \), but not by \( \text{opaR}^{vp} \).

![Figure 3](image-url)

**Figure 3.** Confirmation of \( \Delta \text{opaR}, \Delta \text{luxO}, \Delta \text{opaR}\Delta \text{luxO}, \) and \( \text{luxO}^{D7E} \) mutants by PCR. DNAs from the wild-type strain and the mutants were analyzed by PCR with the primers specific to \( \text{opaR} \) (A) and \( \text{luxO} \) (B). The bands corresponding to the wild type \( \text{opaR} \) and \( \text{luxO} \), and the deleted \( \text{opaR} \) and \( \text{luxO} \) \( (\Delta \text{opaR} \) and \( \Delta \text{luxO}, \) respectively) are indicated.

![Figure 4](image-url)

**Figure 4.** The gene and protein expression levels of (A) \( \text{pirA}^{vp} \) and (B) \( \text{pirB}^{vp} \) in the wild type strain (3HP) compared to those in the \( \text{luxO}^{D7E}, \Delta \text{opaR}, \Delta \text{luxO}, \) and \( \Delta \text{opaR}\Delta \text{luxO} \) mutants. Soluble proteins were extracted from cells collected at \( \text{OD}_{600} \approx 0.6 \) and analyzed by immunoblotting with anti-\( \text{PirA}^{vp} \) or anti-\( \text{PirB}^{vp} \) antibodies (upper panels). Total RNA was extracted from the same batch of bacterial samples, and real-time RT-PCR was carried out using specific primer sets for \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \) (lower panels), respectively. The housekeeping gene, \( \text{gyrB} \) served as an internal control. *: \( p < 0.05 \).

### 2.3. The QS Transcription Factor \( \text{AphB}^{vp} \) Is a Possible Regulator for \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \)

Since the key QS transcription factor, OpaR is evidently not involved in the regulation of \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \), we further analyzed the predicted promoter region of the \( \text{pirA}^{vp}/\text{pirB}^{vp} \) operon, and found that there was a sequence (5'-TGCATAATTTTGTGCAA-3'), which was similar to the consensus sequence of the AphB binding site, 5'-T/G-A-C-A-T/T-A-G-G-T-T/G-T-T/C/A-G-3' [20] (Figure 5). Using real-time PCR, we found that for \( \text{aphB}^{vp} \), the elevated gene expression levels of the \( \text{luxO}^{vp} \) deletion mutants \( \Delta \text{luxO} \) and \( \Delta \text{opaR}\Delta \text{luxO} \) were similar to those seen for \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \) (Figure 6B). Conversely, the expression levels of another important QS transcription factor, \( \text{aphA}^{vp} \), did not correspond so closely to the expression patterns of \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \) (Figure 6A). Taken together, these results suggest that AphB\( ^{vp} \), but not AphA\( ^{vp} \), may be important for the expression of \( \text{pirA}^{vp} \) and \( \text{pirB}^{vp} \).
together, these results suggest that AphBvp, but not AphAvp, may be important for the expression of pirAvp and pirBvp.

Figure 5. Schematic representation of the predicted AphB binding site in the pirAvp/pirBvp promoter region. (A) The predicted pirAvp/pirBvp promoter region is bolded and shaded blue. The putative AphB binding sequence, 5′-TGCATAATTTTGTGCAA-3′, is underlined and shaded yellow. (B) Alignment of the AphB binding sequence on the V. alginolyticus chromosome [20] with the predicted AphBvp binding sequence in the predicted pirAvp/pirBvp promoter region (this study).

Figure 6. The gene expression levels of (A) aphAvp (B) aphBvp in the wild type strain (3HP), luxOΔD47E, ΔopaR, ΔluxO, and ΔopaRΔluxO mutants at OD600~0.6. The expression pattern of aphBvp was similar to the expression patterns of pirAvp and pirBvp. By contrast, the expression pattern of aphAvp was not a good match. The housekeeping gene, gyrB served as an internal control. *: p < 0.05.
2.4. His-AphB<sub>vp</sub> Binds with the Predicted Promoter Region of pirA<sub>vp</sub>/pirB<sub>vp</sub>

In order to verify whether AphB<sub>vp</sub> could bind directly to the predicted AphB<sub>vp</sub> binding site located upstream of pirA<sub>vp</sub>/pirB<sub>vp</sub>, we amplified the fragment 300 bp upstream of the pirA<sub>vp</sub>/pirB<sub>vp</sub> operon by PCR, and mixed it with the indicated concentrations (0, 0.5, 1, 2, 5, 10, 20, and 40 µM) of the recombinant His-tagged Aph proteins His-AphB<sub>vp</sub> and His-AphA<sub>vp</sub>. As shown in Figure 7B, the DNA fragments shifted upward at His-AphB<sub>vp</sub> concentrations of 10 µM and above, showing that His-AphB<sub>vp</sub> was able to bind to this DNA fragment. By contrast, no DNA band shift was seen for His-AphA<sub>vp</sub> (Figure 7A), suggesting that binding to the predicted promoter region of pirA<sub>vp</sub>/pirB<sub>vp</sub> is His-AphB<sub>vp</sub>-specific.

Figure 7. AphB<sub>vp</sub> binds to the predicted pirA<sub>vp</sub>/pirB<sub>vp</sub> promoter region in an electrophoretic mobility shift assay (EMSA). (A) As the concentration of His-AphA<sub>vp</sub> increased, the DNA fragments produced by PCR amplification of the predicted promoter region remained unshifted. (B) By contrast, an upward shift was seen for His-AphB<sub>vp</sub> at concentrations of 10 µM and above.

To further verify the importance of the putative AphB binding sequence in the predicted promoter region of pirA<sub>vp</sub>/pirB<sub>vp</sub>, we truncated the DNA fragment into Fragment 1 (136 bp), which contained the complete AphB binding sequence, and Fragment 2 (116 bp), which contained only half of the AphB binding sequence (Figure 8A). After incubation with the indicated concentrations of His-AphB<sub>vp</sub>, we observed shifting with Fragment 1 at concentrations of 5~10 µM and above, whereas there were no shifts observed at any concentration with Fragment 2 (Figure 8B). These results confirmed the importance of the predicted sequence for AphB<sub>vp</sub> binding and thus for its potential role in the regulation of pirA<sub>vp</sub> and pirB<sub>vp</sub> expression.
Here, we found a relationship between cell density and high expression levels of \( \text{irAvp} \) as the peak of the gene expression levels, we also observed sustained elevated levels of \( \text{PirA} \) and type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin factors in Figures 1 and 2.

It is already known that QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS

### Figure 8

The predicted AphB\(^{vp}\) binding sequence is important for binding AphB\(^{vp}\). (A) The \( \text{pirAvp}/\text{pirBvp} \) promoter region was truncated into fragments that included either the full (Fragment 1) or partial (Fragment 2) predicted AphB\(^{vp}\) binding sequence. The head-tail sequences of these fragments are shown in the box, and the nucleotides in the predicted AphB\(^{vp}\) binding sequence are shaded orange. (B) The EMSA results show that AphB\(^{vp}\) bound only to the full binding sequence (Fragment 1).

### 3. Discussion

\( \text{PirA}^{vp} \) and \( \text{PirB}^{vp} \) have been confirmed as critical pathogenic factors of AHPND [12]. In a previous study, we further showed that \( \text{PirA}^{vp} \) and \( \text{PirB}^{vp} \) formed a heterotetramer in solution, and based on this tetramer’s structural similarity to the Cry toxin, we proposed that the binary toxin may destroy host cells by means of a mechanism similar to that used by Cry [14]. In particular, we suggested that the role of the \( \text{PirA}^{vp} \) component is to recognize the glycan of its receptor on the host cells, after which \( \text{PirB}^{vp} \) penetrates the cell membrane to form an unregulated channel, ultimately leading to critical cell damage [14]. Other reports have further shown that both \( \text{PirA}^{vp} \) and \( \text{PirB}^{vp} \) can bind directly to the receptor \textit{LeAPN1}, and that \( \text{PirB}^{vp} \) was translocated to the cytoplasm and nucleus of hemocytes [22,23], suggesting that the \( \text{PirA}^{vp} \) and \( \text{PirB}^{vp} \) toxins might be involved in other, additional pathogenic mechanisms. Until the present study, however, the mechanisms that might regulate expression of the \( \text{pirA} \) and \( \text{pirB} \) genes themselves had remained unknown. Here, we found a relationship between cell density and high expression levels of \( \text{pirAvp} \) and \( \text{pirBvp} \) in the early log phase (Figure 1). In addition, starting at around the same time as the peak of the gene expression levels, we also observed sustained elevated levels of \( \text{PirA}^{vp} \) and \( \text{PirB}^{vp} \) protein throughout the entire log phase and on into the stationary phase (Figures 1 and 2).

It is already known that QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS system is involved in the regulation of many virulence factors in \textit{Vibrio}, including the genes of the type-III secretion systems (T3SS1 and T3SS2), type-VI secretion systems (T6SS1 and T6SS2), and the thermostable direct hemolysin genes \textit{tdh1} and \textit{tdh2} [24–26]. Here, by using strains with mutations in key molecules of the QS
system, we found that the expression of pirA<sup>vp</sup> and pirB<sup>vp</sup> was also regulated by components of the QS system and that it was negatively regulated by LuxO<sup>vp</sup> (Figure 4).

Although the upstream region of the pirA<sup>vp</sup>/pirB<sup>vp</sup> operon did not include a consensus LuxO binding sequence (5'-TGCAW<sub>3</sub>TGCAA-3', where W stands for A or T; [27]), we found a possible AphB binding site as shown in Figure 5. In addition, we also found that the expression of aphB<sup>vp</sup> was affected by mutation of the QS component luxO<sup>vp</sup> (Figure 6). The upregulated expression pattern of aphB<sup>vp</sup> was similar to the pattern seen for pirA<sup>vp</sup> and pirB<sup>vp</sup> under the same conditions (Figure 4). The possible AphB binding sequence we observed (5'-TGCATATTTTTGCAA-3') diverges from other established binding motifs, such as those of tcpP (5'-TGCAAN<sub>7</sub>TGCAA-3'), toxR (5'-TGCAAN<sub>7</sub>ATGGA-3'), aphB (5'-TGCAAN<sub>7</sub>TGTCA-3'), and a consensus sequence (5'-TGCAAN<sub>7</sub>TGTCA-3'), as well as cadC I (5'-TTCAN<sub>7</sub>ACTTA-3') and cadC II (5'-TACGTN<sub>7</sub>GGCTA-3') [20]. Nevertheless, despite this high divergence, our EMSA results showed that the binding between AphB<sup>vp</sup> and the predicted AphB binding site was both direct and specific (Figures 7 and 8). AphB<sup>vp</sup> (but not AphA<sup>vp</sup>) thus appears to act as an enhancer of pirA<sup>vp</sup> and pirB<sup>vp</sup>. Given AphB<sup>vp</sup>'s role as a regulator of QS, we hypothesize that the QS system regulates the expression of pirA<sup>vp</sup> and pirB<sup>vp</sup> via AphB<sup>vp</sup> (Figure 9, upper left panel). We also found that pirA<sup>vp</sup> and pirB<sup>vp</sup> were down-regulated by the permanently active luxO<sup>vp</sup> mutant even though there was no significant change in aphB<sup>vp</sup>. This suggests that the regulation of the PirA<sup>vp</sup>/PirB<sup>vp</sup> genes may not be controlled only by AphB<sup>vp</sup>, but that other LuxO<sup>vp</sup>-related effectors may also be involved (Figure 9, upper center panel). The proposed regulatory mechanisms and outcomes for LuxO<sup>vp</sup>, AphB<sup>vp</sup>, and PirA<sup>vp</sup>/PirB<sup>vp</sup> in the wild type (3HP) and mutant strains (luxO<sup>D47E</sup>, OpaR, ΔluxO, and ΔopaRΔluxO) are shown in Figure 9.

**Figure 9.** The relationships between LuxO<sup>vp</sup>, AphB<sup>vp</sup> and PirA<sup>vp</sup>/PirB<sup>vp</sup> at OD<sub>600</sub>~0.6. In the first three strains (i.e., wild type strain 3HP, the activated mimic strain luxO<sup>D47E</sup>, and the OpaR deletion strain ΔopaR), the phosphorylated LuxO<sup>vp</sup> acted to limit the free expression of AphB<sup>vp</sup> and its downstream genes, pirA<sup>vp</sup>/pirB<sup>vp</sup>. Conversely, when LuxO was deleted (strains ΔluxO and ΔopaRΔluxO), AphB<sup>vp</sup> was significantly up-regulated, and this further promoted the expression of PirA<sup>vp</sup>/PirB<sup>vp</sup>.
While AphA is a well-studied QS regulator [28,29], there are relatively few studies on AphB. These studies include its regulation of virulence [19,20] and the role it plays in survival under particular conditions [30]. AphB is also a positive regulator of LuxR/OpaR activity, and it activates the expression of the exotoxin Asp [20]. These studies, together with the recent finding that anti-QS compounds may reduce AHPND pathogenicity [18], all suggest that the QS system might be critically important for regulating the virulence of AHPND-causing bacteria.

To this body of evidence, we now add the results of the present study, which suggests that the QS system might be modulating virulence by regulating expression of the pirA\textsuperscript{vp}/pirB\textsuperscript{vp} genes through AphB\textsuperscript{vp}. This new insight into the pathogenic mechanisms of AHPND points toward the QS system as a possible target for therapeutics that might one day be able to control the virulence of AHPND-causing bacteria.

4. Materials and Methods

4.1. Growth Curve Measurement and Sample Collection

All \textit{V. parahaemolyticus} strains (3HP, LuxO\textsuperscript{D47E}, \textit{\Delta}opaR, \textit{\Delta}luxO, and \textit{\Delta}opaR \textit{\Delta}luxO) were activated by culturing on LB+ agar plates (that is, LB agar plates that contained 2% NaCl) at 30 °C for 16 h. From these plates, 3 single colonies were transferred into 5 mL LB+ medium (LB medium that contained 2% NaCl) and incubated at 30 °C for 3 h to OD\textsubscript{600}~1.0. The culture was then diluted 100-fold, transferred into 50 mL fresh LB+ medium and cultured at 30 °C for 15 h with shaking at 200 rpm. Dilutions (1:1000) of these overnight cultures were further sub-cultured into 500 mL LB+ medium in a 2L flask, incubated at 30 °C with shaking at 200 rpm, and the OD\textsubscript{600} was measured every hour for a total of 13 h. At the same time, 3HP cells were collected from part of the culture every hour, and temporarily stored at −80 °C prior to subsequent RNA and protein extractions. Other batches of sample cells of 3HP, LuxO\textsuperscript{D47E}, \textit{\Delta}opaR, \textit{\Delta}luxO, and \textit{\Delta}opaR \textit{\Delta}luxO were collected at low cell density (LCD; OD\textsubscript{600}~0.6) and temporarily stored at −80 °C for later use.

4.2. RNA Extraction and Real-Time PCR

Total bacterial RNA was extracted using RareRNA reagent (Blossom Biotechnologies, Inc.; Taipei, ROC). DNasel (Invitrogen) was used to digest any DNA contamination. From 1 \muL of total RNA, cDNA was synthesized by using M-MLV reverse transcriptase (Promega; Madison, WI, USA) with random hexamers. Using specific primers (Table 1), real-time PCR was carried out to quantify the expression levels of target genes (pirA\textsuperscript{vp}, pirB\textsuperscript{vp}, aphA\textsuperscript{vp}, and aphB\textsuperscript{vp}) and an internal control gene (gyrB\textsuperscript{vp}, a housekeeping gene). The reaction mixture contained 1 \muL cDNA, 0.2 \muM forward primer, 0.2 \muM reverse primer, 1x ChamQ Universal SYBR qPCR Master Mix (Vazyme Biotech Co. Ltd.; Nanjing, China) in a total volume of 20 \muL, and thermal cycling was performed using a LightCycler\textsuperscript{®} 96 System (Roche; Basel, Schweiz) as follows: 95 °C for 2 min followed by 40 cycles of 95 °C for 10 s and 60 °C for 30 s, and an extension cycle of 95 °C for 10 s, 65 °C for 60 s and 97 °C for 60 s.

To calculate ΔC\textsubscript{i}, the threshold cycle values of the internal control gene (C\textsubscript{i} gyrB) were first subtracted from the threshold cycle values of the target genes. Next, either the initial ΔC\textsubscript{i} for the “1-h” timepoint was subtracted from the ΔC\textsubscript{js} of the other timepoints (i.e., 2–13 h), or else the ΔC\textsubscript{i} for the wild-type 3HP strain was subtracted from the ΔC\textsubscript{i} of all the groups (3HP, LuxO\textsuperscript{D47E}, \textit{\Delta}opaR, \textit{\Delta}luxO, and \textit{\Delta}opaR \textit{\Delta}luxO) to obtain ΔΔC\textsubscript{i} values. The fold change of the gene expression levels was then expressed as 2\textsuperscript{−ΔΔC\textsubscript{i}} [31], and the data presented as mean ± SD. Statistically significant differences were tested using an unpaired Student’s \textit{t}-test (\textit{p} < 0.05).
### Table 1. Primers used in this study.

| Primer Name | Primer Sequence (5′→3′) | Usage |
|-------------|------------------------|-------|
| opaR-1      | GAGACCGTTGAGCATCG       | Mutant construction |
| opaR-2      | CAGGTACCAGAAGTAAACGCTCA | Mutant construction |
| opaR-3      | CAGAGCTCGGTTACGTTTACCAC | Mutant construction |
| opaR-4      | GTCTAGAGTGGGTTAGGTAGGT  | Mutant selection |
| opaR-5      | GGTCTAGAGTGGTACTAACGGTG | Mutant selection |
| luxO-1      | GAGAGCTCCGTATTTCCGCGCAAG | Mutant construction |
| luxO-2      | CTCAGTTCCGCTTACACTCAACCATC | Mutant construction |
| luxO-3      | CAGGTACCAGAAGTAGCGCAAGTG | Mutant construction |
| luxO-4      | CGTCTAGAGTGGGTTAGGTAGGT  | Mutant selection |
| luxO-5      | GGTCTAGAGTGGTACTAACGGTG | Mutant selection |
| luxO-6      | GGTCTAGAGTGGTACTAACGGTG | Mutant selection |
| pirAQF      | TTAGCCACTTTCCAGCCGCGCG  | qPCR |
| pirAQR      | CCGGAAGTCGGCTTATGTGCTGTG | qPCR |
| pirBQF      | TCCTATACGCCCAGCGCGCGAG  | qPCR |
| pirBQR      | TTTCACTCCTCTGATTGCGCA   | qPCR |
| aphAQF      | GAAAATTTGTTGTGGTGGC     | qPCR |
| aphAQR      | GCGCTTTCCATTTTCTTGTGA  | qPCR |
| aphBQF      | TAGGATTTTCCGCTTGGC     | qPCR |

#### 4.3. Protein Extraction and Western Blots

Two batches of bacterial samples were removed from storage at −80 °C and lysed immediately using B-PER™ Bacterial Protein Extraction Reagent (ThermoFisher Scientific; Waltham, MA, USA) containing 1 mM PMSF, 1 mM EDTA, and 120 µg/mL DNaseI. The suspensions were inverted at room temperature for 10 min, and the cell debris was removed by centrifuging at 13,000 × g for 10 min. Two micrograms of cell lysates were separated by 12.5% SDS-PAGE, transferred onto a PVDF membrane, and blocked with 5% skim milk at 4 °C overnight. The blots were then hybridized with chicken anti-PirA<sub>vp</sub> or chicken anti-PirB<sub>vp</sub> polyclonal antibodies (1:5000 diluted with 5% skim milk). After 1 h of incubation at room temperature, the blots were washed 3 times with PBST solution (1 × PBS contained 0.1% Tween-20). The blots were further incubated with donkey anti-chicken-HRP conjugated secondary antibody (Jackson; West Grove, PA; 1:10,000 diluted with 5% skim milk) at room temperature for 1 h. Following 3 more washes, the protein bands were visualized using a chemiluminescence reagent (GE Healthcare; Chicago, IL, USA) and detected with an Amersham Imager 600 (GE Healthcare; Chicago, IL, USA). For loading controls, 8 µg of cell lysates were separated with another 12.5% SDS-PAGE, and stained with Coomassie blue.
4.4. Construction of the ΔopaR, ΔluxO, ΔopaRΔluxO, and luxO<sup>D47E</sup> Mutants

The in-frame ΔopaR, ΔluxO, and ΔopaR ΔluxO mutants were constructed by in vivo allelic exchange as described previously [21]. Briefly, DNA fragments from the down- and up-stream regions of _opaR_ and _luxO_ were amplified, respectively, with the primer sets _opaR-1_/ _opaR-2_ and _opaR-3_/ _opaR-4_, and _luxO-1_/ _luxO-2_ and _luxO-3_/ _luxO-4_ (Table 1). These fragments were cloned into pGEM-T® Easy vector (Promega; Madison, WI, USA) in the correct orientation to generate a recombinant fragment containing a 627 bp- and a 1323 bp-deletion in _opaR_ and _luxO_, respectively. The DNA fragments were removed from the pGEMT®-easy vector by enzyme digestion with _Sac_ and _Sal_, respectively, and then cloned into the suicide vector pDS132. The suicide plasmids containing either the _ΔopaR_ or _ΔluxO_ fragment were transformed into _Esherichia coli_ S17-1λpir [21], and then transferred into _V. parahaemolyticus_ 3HP by conjugation to facilitate allelic exchange to produce the mutants. The double mutant was obtained by introducing the _ΔluxO_ mutant into an already-constructed _ΔopaR_ mutant by the method described above. For the _luxO<sup>D47E</sup>_ mutant, a 2340-bp fragment amplified by the primers _luxO-1_ and _luxO-16_ was given a single nucleotide mutation (GAT to GAG) using a QuikChange® Site-Directed Mutagenesis Kit (Stratagene; La Jolla, CA, USA). This _luxO<sup>D47E</sup>_-containing fragment was introduced into _V. parahaemolyticus_ 3HP by allelic exchange to generate the mutant.

4.5. Confirmation of the ΔopaR, ΔluxO, ΔopaRΔluxO and luxO<sup>D47E</sup> Mutants by PCR

Genomic DNA was extracted from 3HP and the mutants using a Genomic DNA Extraction Kit (Bioman; New Taipei City, ROC) according to the manufacturer’s instructions. The _opaR_ and _luxO_ genes from all of the isolated mutants were then checked by PCR with _opaR_- and _luxO-specific_ primers _opaR-5_/ _opaR-6_ and _luxO-5_/ _luxO-6_ (Table 1), respectively. The DNA sequences were also determined to confirm that the deletion was in-frame, or, in the case of _luxO<sup>D47E</sup>_, that the single nucleotide mutation was correct.

4.6. Plasmid Construction for Recombinant Protein Expression

The codons in the coding sequences of _aphA<sup>vp</sup>_ ((CP045794; region 937101-937640) and _aphB<sup>vp</sup>_ (WP069541384) were optimized, synthesized, and cloned into pET21b vector (Novagen; Madison, WI, USA) by GenScript Inc. (Piscataway, NJ, USA). Using the resulting plasmids as templates, the _aphA<sup>vp</sup>_ and _aphB<sup>vp</sup>_ genes were amplified with the primer sets _AphA-F-NdeI_/ _AphA-R-Xhol_ and _AphB-F-NdeI_/ _AphB-R-Xhol_ (Table 1), respectively, and then subcloned into pET28a vector (Novagen; Madison, WI, USA). The resulting plasmids were named _aphA<sup>vp</sup>_-pET28a and _aphB<sup>vp</sup>_-pET28a, respectively.

4.7. Expression and Purification of Recombinant His-AphA and His-AphB

To express the recombinant AphA<sup>vp</sup> and AphB<sup>vp</sup>, the _aphA<sup>vp</sup>_-pET28a and _aphB<sup>vp</sup>_-pET28a plasmids were, respectively, transformed into _E. coli_ strain BL21 (DE3) cells. For AphA<sup>vp</sup>, the transformed cells were inoculated into 50 mL of fresh LB medium and grown at 37 °C for 12–14 h. Three ml of this overnight culture was then added to 500 mL of fresh LB medium in a 2L flask, and grown at 37 °C until the OD<sub>600</sub> of the culture reached 0.4. IPTG was then added to a final concentration of 0.4 mM, and the culture was incubated at 16 °C for 20 h. The cells were then collected, resuspended in binding buffer (20 mM Tris-base, 500 mM NaCl, 20 mM imidazole, pH 8.0) containing 1 mM PMSF, 100 µg/mL lysozyme and 10 µg/mL DNase I, and homogenized by sonication on ice. After the cell debris was removed by centrifugation, the supernatant was filtrated using a 0.45 µm filter and loaded onto a 5 mL HisTrap HP column (GE Healthcare; Chicago, IL, USA). The column was washed with 100 mL of binding buffer and then eluted with a 20–500 mM imidazole gradient. The eluted recombinant protein was concentrated and loaded onto a Superdex 75 gel filtration column (GE Healthcare; Chicago, IL, USA) using 20 mM Tris-base, 500 mM NaCl, pH 8.0 as a running buffer. The protein concentration was measured by the Bradford method. For AphB<sup>vp</sup>, all of the culture and purification processes were the
same as for AphA<sup>vp</sup>, except that for the subculture step, 10 mL of the overnight culture was inoculated into the 500 mL of fresh LB+ medium.

4.8. Electrophoretic Mobility Shift Assay (EMSA)

ProOpDB (Prokaryotic Operon DataBase) was used to predict possible promoter sequences in the upstream region of the pir<sup>A</sup>/pir<sup>B</sup> operon [32]. The DNA fragment that contained this predicted promoter region was further amplified by PCR using the primer set pir<sup>AB</sup> promoter-F1/Ndel/pir<sup>AB</sup> promoter-R1-Xhol, pir<sup>AB</sup> promoter-F2/Ndel/pir<sup>AB</sup> promoter-R2-Xhol (for Fragment 1, which included the complete predicted AphB binding sequence) or pir<sup>AB</sup> promoter-F3/pir<sup>AB</sup> promoter-R3-Xhol (for Fragment 2, which included only a partial predicted AphB binding sequence) (Table 1). For EMSA, recombinant His-AphA or His-AphB was mixed with the DNA fragment in a reaction buffer (20 mM Tris, pH 8.0, 100 mM NaCl) to final concentrations of 0, 0.5, 1, 2, 5, 10, 20, 40 µM (proteins), and 135 nM (DNA), and incubated at 25 °C for 20 min. The reactants were analyzed with 2% agarose gels, and stained by SYBR® Green I nucleic acid gel stain (Sigma-Aldrich; Burlington, MA, USA).
