**Background.** *Brachycephalus* are among the smallest terrestrial vertebrates in the world. The genus encompasses 34 species endemic to the Brazilian Atlantic Rainforest, occurring mostly in montane forests, with many species showing microendemic distributions to single mountaintops. It includes diurnal species living in the leaf litter and calling during the day, mainly during the warmer months of the year. The natural history of the vast majority of the species is unknown, such as their advertisement call, which has been described only for seven species of the genus. In the present study, we describe the advertisement call of *Brachycephalus albolineatus*, a recently described microendemic species from Santa Catarina, southern Brazil.

**Methods.** We analyzed 34 advertisement calls from 20 individuals of *B. albolineatus*, recorded between 5–6 February 2016 in the type locality of the species, Morro Boa Vista, on the border between the municipalities of Jaraguá do Sul and Massaranduba, Santa Catarina, southern Brazil. We collected five individuals as vouchers (they are from the type series of the species). We used the note-centered approach to describe the advertisement calls of the species.

**Results.** *Brachycephalus albolineatus* have a long advertisement call of 40–191 s (mean of 88 s) composed of 8–29 notes (mean of 17 notes) emitted at a rate of 6–18 notes per minute (mean of 11 notes per minute) and at a note dominant frequency of 5–7 kHz (mean of 6 kHz). Advertisement calls are composed of isolated notes and note groups (two notes involved in each particular note group); the former is composed by one to three pulses (mean of 2.0) and the note groups by two or three pulses in each note (mean of 2.7). Most advertisement calls present both isolated notes and note groups, with a few cases showing only the former. Note groups are emitted invariably in the last third of the advertisement call. Most isolated notes escalate their number of pulses along the advertisement call (1 to 2, 1 to 3 or 2 to 3). Note duration of isolated notes varies from 0.002–0.037 s (mean of 0.020 s) and duration of note group vary from 0.360–0.578 s (mean of 0.465 s).

**Discussion.** Individuals increase the complexity of their calls as they proceed, incorporating note groups and pulses per note. Intra-individual variation analysis also demonstrated that less structured advertisement calls (i.e. with notes with fewer pulses) are not stereotyped. It is possible that isolated notes and note groups could have distinct functions, perhaps territorial defense and mating, respectively. We argue that using a note-centered approach facilitates comparisons with calls of congeners, as well as underscores the considerable differences in call structure between species in a single group and among
species groups.
Advertiseinent call of *Brachycephalus albolineatus* (Anura: Brachycephalidae)

Running headline: Advertisement call of *B. albolineatus*

**Abstract**

**Background.** *Brachycephalus* are among the smallest terrestrial vertebrates in the world. The genus encompasses 34 species endemic to the Brazilian Atlantic Rainforest, occurring mostly in montane forests, with many species showing microendemic distributions to single mountaintops. It includes diurnal species living in the leaf litter and calling during the day, mainly during the warmer months of the year. The natural history of the vast majority of the species is unknown, such as their advertisement call, which has been described only for seven species of the genus. In the present study, we describe the advertisement call of *Brachycephalus albolineatus*, a recently described microendemic species from Santa Catarina, southern Brazil.

**Methods.** We analyzed 34 advertisement calls from 20 individuals of *B. albolineatus*, recorded between 5–6 February 2016 in the type locality of the species, Morro Boa Vista, on the border between the municipalities of Jaraguá do Sul and Massaranduba, Santa Catarina, southern Brazil.
We collected five individuals as vouchers (they are from the type series of the species). We used the note-centered approach to describe the advertisement calls of the species.

**Results.** *Brachycephalus albolineatus* have a long advertisement call of 40–191 s (mean of 88 s) composed of 8–29 notes (mean of 17 notes) emitted at a rate of 6–18 notes per minute (mean of 11 notes per minute) and at a note dominant frequency of 5–7 kHz (mean of 6 kHz). Advertisement calls are composed of isolated notes and note groups (two notes involved in each particular note group); the former is composed by one to three pulses (mean of 2.0) and the note groups by two or three pulses in each note (mean of 2.7). Most advertisement calls present both isolated notes and note groups, with a few cases showing only the former. Note groups are emitted invariably in the last third of the advertisement call. Most isolated notes escalate their number of pulses along the advertisement call (1 to 2, 1 to 3 or 2 to 3). Note duration of isolated notes varies from 0.002–0.037 s (mean of 0.020 s) and duration of note group vary from 0.360–0.578 s (mean of 0.465 s).

**Discussion.** Individuals increase the complexity of their calls as they proceed, incorporating note groups and pulses per note. Intra-individual variation analysis also demonstrated that less structured advertisement calls (i.e. with notes with fewer pulses) are not stereotyped. It is possible that isolated notes and note groups could have distinct functions, perhaps territorial defense and mating, respectively. We argue that using a note-centered approach facilitates comparisons with calls of congeners, as well as underscores the considerable differences in call structure between species in a single group and among species groups.

**Introduction**

*Brachycephalus* are among the smallest terrestrial vertebrates in the world (Rittmeyer *et al.* 2012), with most species not exceeding 2.5 cm in body length. The genus includes 34 species (Frost 2017), occurring from the southern Bahia to northeastern Santa Catarina, Brazil (Bornschein *et al.* 2016a; see also Pie *et al.* 2013). Most *Brachycephalus* species, particularly in the *B. pernix* species group (see below), are microendemic, occurring in one or a few adjacent mountaintops, with total extents of occurrence comparable to the smallest ranges of species around world (Bornschein *et al.* 2016a). Species are diurnal, living in the leaf litter in forests of the Atlantic Rainforest domain (Bornschein *et al.* 2016a and compilation therein). Direct
development, with a reduced number of eggs laid on the soil (Pombal Jr. 1999), was
demonstrated for *B. ephippium* (Heyer et al. 1990, Pombal Jr. 1999), and this is assumed as the
reproductive pattern for the genus. *Brachycephalus* is characterized by extreme miniaturization,
with is possible related to a reduced number and size of digits (Hanken & Wake 1993, Yeh 2002,
Clemente-Carvalho et al. 2009) and loss of some morphological features of the auditory
apparatus (Silva, Campos & Sebben 2007). Some species are brightly colored, with neurotoxins
found in the skin of two aposematic species (Sebben et al. 1986, Pires Jr. et al. 2002, 2003, 2005,
Schwartz et al. 2007), possibly originated from intestinal bacteria (Schwartz et al. 2007). The
species of the genus have been segregated into three phenetic groups, namely the *B. ephippium*,
*B. didactylus*, and *B. pernix* species groups (Ribeiro et al. 2015). Possibly due to historical
evolutionary processes (Bornschein et al. 2016a, Firkowski et al. 2016), *Brachycephalus* species
are almost exclusively allopatric or parapatric, with few cases of syntopy (Bornschein et al.
2016a).

There has been a recent increase in the description of new species within *Brachycephalus*,
with 20 species described in the last 10 years (Frost 2017). However, the natural history of the
vast majority of the species is unknown (see review of ecological studies in Bornschein et al.
[2016a]). Call descriptions of the species are scarce, which is surprising, given that individuals of
the species are usually located by their calls, often emitted at locally high male densities (one
person might hear dozens of males from a single hearing spot). Advertisement calls were
described for *B. ephippium* (Pombal Jr., Sazima & Haddad 1994, Goutte et al. 2017), *B. hermogenesi* (Verdade et al. 2008), *B. pitanga* (Araújo et al. 2012, Tandel et al. 2014, Goutte et
al. 2017), *B. tridactylus* (Garey et al. 2012), *B. crispus* (Condez et al. 2014), *B. sulfuratus*
(Condez et al. 2016), and *B. darkside* (Guimarães et al. 2017).

Given that *Brachycephalus* is a group with mostly allopatric species, it is of great interest
to investigate the evolution pattern of their calls. In allopatry, one could expect great similarity
between the call of different species (Bornschein et al. 2007, Mauricio et al. 2014), due to a lack
of selective pressure to avoid hybridization of closely-related species. However, this needs to be
tested for *Brachycephalus*. In the present study, we describe the advertisement call of *B.
albolineatus*, a member of the *B. pernix* group (Bornschein et al. 2016b). *Brachycephalus
albolineatus* was recently described based on a series of eight specimens collected at the type
locality, Morro Boa Vista, Santa Catarina, southern Brazil (Bornschein et al. 2016b).
Methods

We recorded individuals of *Brachycephalus albolineatus* on 25 October 2012 and on 5–6 February 2016 at the type locality of the species, i.e. Morro Boa Vista (26°30’58” S, 49°03’14” W; 820–835 m above sea level), on the border between the municipalities of Jaraguá do Sul and Massaranduba, state of Santa Catarina, southern Brazil. We collected vouchers according to permits issued by ICMBIO - SISBIO (no. 20416–2). Vouchers belong to the type material of the species, which was deposited in Museu de História Natural Capão da Imbuia (MHNCI), Curitiba, Paraná state and Museu Nacional (MNRJ), Rio de Janeiro, Rio de Janeiro state, Brazil. Analyzed recordings were carried out on 5–6 February 2016 from 9:00–12:00 a.m. and from 15:00–18:00 p.m. Climatic conditions during recordings were characterized by air temperature = 20.8–21.4 °C, soil temperature = 19.4–20.0 °C, and relative air humidity = 86–100%. We made numbered markings on the vegetation above the recorded individuals in the field to determine whether new recordings were from the same individuals, in order to build up the dataset both in terms of more individuals as well as intra-individual variation, with more than one recording from the same individual. Calls were recorded using the digital recorders Sony PCM-D50 and PCM-M10, both with sampling frequency rate of 44.1 kHz and 16-bit resolution, and Sennheiser ME 66 microphones. Recordings were deposited in MHNCI. Sound samples were analyzed with Raven Pro 1.5 (Bioacoustics Research Program 2012). Time domain variables were measured from oscillograms and frequency domain variables were measured from spectrograms. Spectrogram features were defined with a 256-point Fast Fourier Transform (FFT), a 3-dB Filter bandwidth of 492 Hz, Hann window, 50% overlap, and a spectrogram color scheme of Standard Gamma II in Raven Pro and Jet in Raven Lite. Final spectrograms, as well as diagnostic plots, were generated using the Seewave package, v. 2.0.5 (Sueur, Aubin & Simonis 2008) of the R environment, v. 3.2.2 (R Core Team 2015) using the same window size and overlap settings as in Raven Pro, but resampling the audio files at 22.05 kHz.

We used the note-centered approach *sensu* Köhler et al. (2017) to define the advertisement call of the species. We determined the end of a given call and the beginning of the next one by the long period of silence between them (Köhler et al. 2017), which might last for several minutes and thus is considerably longer than the call itself. We described the advertisement calls following features and criteria of Köhler et al. (2017). We took the liberty of
describing the general features of Köhler et al. (2017) also for parts of the call, in order to clarify
the distinctions observed in particular parts of the advertisement calls of Brachycephalus
albineatus. We used the following features, which can be seen in Fig. 1: 1) call duration (s); 2)
duration of the call including only isolated notes (s); 3) duration of the call including only note
groups (s); 4) note rate (notes per minute); 5) note rate of the call including only isolated notes
(notes per minute); 6) note rate of the call including only note groups (notes per minute); 7)
number of notes per call; 8) number of isolated notes per call; 9) number of note groups per call;
10) number of pulses per isolated notes; 11) number of pulses per note in note groups; 12) note
duration of isolated notes (s); 13) duration of note group (s); 14) inter-note interval in isolated
notes (s), defined as the time from the end of one isolated note to the beginning of the next note
isolated note; 15) inter-note group interval (s), defined as the time from the end of one note
group to the beginning of the next note group; 16) inter-note interval within note groups (s),
defined as the time from the end of the first note to the beginning of the next note of the same
note group; 17) note dominant frequency (kHz); 18) highest frequency (kHz); and 19) lowest
frequency (kHz). The note rate was calculated taking into account the time from the beginning of
the first note to the beginning of the last note of the calls (or call intervals) and the number of
notes included in this counted time (the last note is not included; Köhler et al. [2017]; see also
Cocroft & Ryan [1995]). The dominant frequency across all notes in a call sample was calculated
with the function dfreq from the R package seewave. This function brings as an output a plot
with all dominant frequencies in a specific file or file segment. Alternatively, the output can be a
vector of dominant frequency values. All the default arguments of the function were followed,
with the exception of the overlap, for which we chose the value of 90% and the amplitude
threshold of signal detection, whose value we determined as of 5%. We measured the highest
and lowest frequencies from notes.

Results
We recorded calls from 29 individuals of Brachycephalus albolineatus but analyzed 34
advertisement calls from 20 individuals, five of which were collected as vouchers (MHNCI
10296–9, MNRJ 90349). We recorded eight individuals 2–4 times ($\bar{x} = 2.75$ times per
individual). The calls we deposited resulted in 34 separate recordings (MHNCI 001–34).
Brachycephalus albolineatus emitted a relatively long advertisement call, between 39.93–191.14 s ($\bar{x} = 88.37 \pm 35.73$ s; Table 1; see feature #1 in Fig. 1). Thereafter, the individual remains silent for several minutes, occasionally for more than 35 min, when it emits a new advertisement call. A graphical representation of the temporal sequence of notes in each call is shown in Fig. 2. The note rate was 5.89–18.09 notes per minute ($\bar{x} = 11.44 \pm 3.22$ notes per minute; Table 1; see feature #4 in Fig. 1). Advertisement calls included 8–29 notes ($\bar{x} = 17.26 \pm 6.38$ notes; Table 1; see feature #7 in Fig. 1).

The advertisement calls of the species included both isolated notes and note groups (in this case, with two notes involved in each particular note group; Fig. 3). Advertisement calls could be composed only by isolated notes (23.5% of advertisement calls), but usually included both isolated notes and note groups (Table 2). Every advertisement call with isolated notes and note groups began with the former and then changed to note groups (Table 2, Fig. 2). Note groups contains, on average, 31.7% of the notes of the entire advertisement call ($\pm 24.4$%; range of 0–76.2%; Table 1; see feature #9 in Fig. 1) and span, on average, 23.42 s ($\pm 17.87$ s; range of 0.41–60.32 s; see feature #3 in Fig. 1) as opposed to a mean of 53.71 s ($\pm 25.38$ s; range of 18.39–98.90 s; Table 1; see feature #2 in Fig. 1) of the part of the advertisement calls with only isolated notes. The part of the advertisement call with only note groups also had a faster note rate, with 18.60 notes issued per minute, on average ($\pm 3.84$ note per minute; range of 12.81–27.16 notes per minute; see feature #6 in Fig. 1), against 10.25 notes per minute on average ($\pm 1.61$ note per minute; range of 7.28–13.62 notes per minute; Table 1) in the part of the call with isolated notes (when note groups occurs; see feature #5 in Fig. 1).

The number of pulses per isolated notes varies from 1–3 ($\bar{x} = 2.00 \pm 0.59$; Table 1; Fig. 3; see feature #10 in Fig. 1). The isolated notes that initiate the advertisement call do it with one pulse (8 advertisement calls) or two pulses (16 advertisement calls; Table 2). However, most of isolated notes along the advertisement call escalated the number of pulses (1 to 2, 1 to 3 or 2 to 3; 18 advertisement calls), whereas the isolated notes maintained a constant number of pulses only in six of the advertisement calls (2 to 2; Table 2). The number of pulses per note in note groups varied from 2–3 ($\bar{x} = 2.70 \pm 0.46$; Table 1; Fig. 3; see feature #11 in Fig. 1). The total number of pulses in note groups varied from 4–6 ($\bar{x} = 5.40 \pm 0.82$; Table 1). Occurred four combinations of number of pulses in note groups (2–2 to 3–3), being more common the
combination of 3–3 pulses (61.7%; Table 1 and 2). All pulses both in isolated notes and note
groups are interrupted units of the subsequent pulses, isolated by short moment of silence.

Note duration of isolated notes varies from 0.002–0.037 s ($\bar{x} = 0.020 \pm 0.007$ s) and
duration of note groups varies from 0.360–0.578 s ($\bar{x} = 0.465 \pm 0.053$ s; Table 1; see features #12
and #13 in Fig. 1). The inter-note interval in isolated notes is, on average, 6.663 s (4.092–12.248
± 1.705 s; see feature #14 in Fig. 1) and the inter-note group interval is, on average, 6.871 s
(4.322–10.678 ± 1.768 s; Table 1; see features #15 in Fig. 1). The inter-note interval within note
groups is, on average, 0.412 s (0.319–0.526 ± 0.050 s; Table 1; see feature #16 in Fig. 1). The
note dominant frequency varies from 5.34–7.32 kHz ($\bar{x} = 6.38 \pm 0.30$ kHz; Table 1). Finally, the
highest frequency spans from 7.11–9.85 kHz ($\bar{x} = 8.44 \pm 0.49$ kHz) while the lowest frequency
span from 3.09–5.21 kHz ($\bar{x} = 4.07 \pm 0.45$ kHz; Table 1).

Discussion
In this study we used a note-centered approach (sensu Köhler et al. [2017]) to describe the
advertisement call of Brachycephalus albolineatus. We argue that there are two advantages for a
note-centered approach to describe the calls of species of the B. pernix group. First, it is
consistent with descriptions of calls of the species of the B. ephippium and B. didactylus groups
(Table 3). For instance, in the B. ephippium group, the advertisement call of B. crispus has been
described as “a long and low-intensity buzz with a regular repetition of notes” (Condez et al.
2014); the call of B. darkside “is characterized by pulsed notes emitted in extremely long
sequences” (Guimarães et al. 2017), whereas the call of B. pitanga “[...] consists of low-intensity
pulsed notes uttered in a long series” (Araújo et al. [2012]; see Pombal Jr., Sazima & Haddad
1994) for a similar description in the case of B. ephippium). Likewise, in the B. didactylus
group, the call of B. hermogenesi “may be simple, constituted by a single note, or complex,
composed of groups of two to seven similar notes” (Verdade et al. 2008), whereas the call of B.
sulfuratus is “long, composed of a set of 4–7 high-frequency notes [...] repeated regularly”
(Condez et al. 2016). In all those cases, the call was considered as the entire sequence of notes.
On the other hand, Garey et al. (2012) considered single notes as calls and largely overlooked
any patterns over longer periods of time. Second, using a note-centered approach facilitates
comparisons with calls of congeners, as well as underscores the considerable differences in call
structure between species in a single group and among species groups.
There are only a few species of *Brachycephalus* with described advertisement calls. In Table 3 we summarize all data and features used in those descriptions. It is striking the extent to which descriptions vary in the number of features used and in how often they lacked important details, such as methodological procedures and sample size. These issues make it difficult to conduct a more precise comparison with the call of *B. albolineatus*. Nevertheless, *B. albolineatus* is the only known species with an advertisement call that is structurally modified along its emission, i.e. more structured (with notes with increasingly more pulses and with note groups).

However, as stated above, we do not rule out the possibility that the advertisement call of *B. tridactylus* indeed exhibits some level of structuring such as that of *B. albolineatus*. Another striking difference is how much the note of *B. albolineatus* is shorter than that of *B. tridactylus* (Garey et al. 2012), both of the *B. pernix* group (average of 0.020 s and 0.11 s, respectively).

*Brachycephalus albolineatus* have a very reduced number of pulses in isolated notes in comparison with the species of the *B. ephippium* and *B. didactylus* groups, i.e. a mean of two pulses against means of 6.3 pulses in *B. darkside* (Guimarães et al. 2017), 10.0 pulses in *B. crispus* (Condez et al. 2014), 10.9 and 11.1 pulses in *B. pitanga* (Araújo et al. 2012, Tandel et al. 2014), and 12 pulses in *B. ephippium* (Pombal Jr., Sazima & Haddad 1994; Table 3), in species of the *B. ephippium* group, and against a mean of 8.8 pulses in *B. sulfuratus*, of the *B. didactylus* group (Condez et al. 2016; Table 3). *Brachycephalus albolineatus* has the highest interval in the range of note dominant frequency, that include a variation of 2 kHz, only slightly comparable to the range variation of 1.2 kHz of *B. pitanga* (Tandel et al. 2014; Table 3). Meanwhile it is premature to provide a discussion about this variation, given that most of the available data of dominant frequency in *Brachycephalus* only report their average values (Table 3). It should be noted that the large frequency range of the “dominant frequency” for *B. darkside* presented by Guimarães et al. (2017), including a variation of 3.3 kHz, is not comparable to the variation in *B. albolineatus* because the measurement refers to a frequency range (Table 3). The one-pulse notes of *B. albolineatus* may represent “warming notes” (sensu Bornschein et al. 2007), which refers to notes beginning a call and that are attenuated (e.g. less intense [less audible]), although one-pulse notes also appear along the call in some advertisement calls.

In relation to the number of pulses, the homology between what has been termed as a note and a pulse in *Brachycephalus* is still uncertain (Table 3). One way of standardizing this criterion would be to associate a note with an airflow, that is, with an increase and decrease of
the vocal sac (McLister, Stevens & Bogart 1995). This would be an objective form of definition and standardization, but it would require one to overcome the difficulty in observing a Brachycephalus calling, or even better, to capture its call in a slow-motion video to associate the movement of the vocal sac with the spectrogram. A possible result of this analysis could be verifying that the pulses could be defined as notes in some species.

Apparently, there is a trend of individuals of Brachycephalus albolineatus to invest progressively more energy along the emission of each particular advertisement calls. There are three sources of evidence for this: 1) advertisement calls normally escalated, incorporating note groups at the last third part of the call (76%) and 2) pulses per note increased during the emission of isolated notes (up to three; 62%); and 3) note groups usually had 3–3 pulses per note (62%), which is the combination of the groups with highest number of pulses (Table 2). Intra-individual variation analysis also demonstrated that less structured advertisement calls (i.e. with notes with less pulses) are not fixed individually and can vary in the course of an hour. In the only species of the B. pernix group with its advertisement calls described to date, B. tridactylus (Garey et al. 2012), there was no evidence of escalation in structure. It is possible that the advertisement calls with isolated notes and note groups could have distinct functions, perhaps territorial defense when composed only by the former and territorial defense plus mating when composed by isolated notes and note groups. There is a parallel between the differences of isolates notes versus note groups of B. albolineatus and the “territorial call” / “aggressive call” versus advertisement call of B. pitanga (Araújo et al. 2012) and B. darkside (Guimarães et al. 2017). In both of these territorial / aggressive calls there are shorter notes with reduced number of pulses that in the advertisement calls, like the isolated notes of B. albolineatus that span 0.002–0.037 s (\(\bar{x} = 0.020\) s) and have 1–3 pulses (\(\bar{x} = 2.0\) pulses) whereas note groups span 0.360–0.578 s (\(\bar{x} = 0.465\) s) and have 4–6 pulses (\(\bar{x} = 5.4\) pulses).

In a recent study, Goutte et al. (2017) suggested that Brachycephalus ephippium and B. pitanga are insensitive to the sound of their own calls. This raises some questions about the validity of discussions about the possible reproductive and behavioral use of calls in the case of B. albolineatus, as well as for the use of calls in the taxonomy of the group. Goutte et al. (2017) suggest that calls may have been maintained in the studied species because of the call side effects (e.g. vocal sac movement) or by evolutionary inertia, for example. The relevant issue to be discussed here is that B. ephippium and B. pitanga, both members of the B. ephippium group,
present vocal and visual behavioral (vocal sac movements) above the leaf litter (Goutte *et al.* 2017), unlike *B. albolineatus* and all other species of the *B. pernix* group (MRB *et al.*, per. obs.), which call exclusively under the leaf litter and vocal sac movements are not visible. We do not abandon the hypothesis that species of the *B. pernix* and *B. didactylus* groups have a more complete auditory system than *B. ephippium* and *B. pitanga* and the ability to perceive their own calls. This is an interesting subject brought only now to the fore and open to further discussion.

**Conclusions**

*Brachycephalus albolineatus* is the first species in the genus whose advertisement call has been recognized as increasing in complexity over the course of its emission. Its advertisement call is long and composed by isolated notes and note groups, which tend to be emitted during the last third of the call. Intra-individual variation demonstrates that calls can be composed only by isolated notes or by isolated notes and note groups in a subsequent call. Number of pulses per notes escalates along the call. These results underscore how a note-centered approach is able to reveal important aspects of the temporal dynamics of the advertisement call of the studied species.

Figure 1. Representation of some features considered in the description of the advertisement call of *Brachycephalus albolineatus* on a schematic call. Numbers correspond with the order of descriptions in the methods. 1) Call duration (s); 2) duration of the call including only isolated notes (s); 3) duration of the call including only note groups (s); 4) note rate (notes per minute); 5) note rate of the call including only isolated notes (notes per minute); 6) note rate of the call including only note groups (notes per minute); 7) number of notes per call (10 notes in the example); 8) number of isolated notes per call (seven notes in the example); 9) number of note groups per call (three notes in the example); 10) number of pulses per isolated notes (three in the example); 11) number of pulses per note in note groups (3–3 in the example); 12) note duration of isolated notes (s); 13) duration of note group (s); 14) inter-note interval in isolated notes (s); 15) inter-note group interval (s); and 16) inter-note interval within note groups (s).

Figure 2. Graphical representation of the emission of isolated notes and note groups of the advertisement calls (AC) of *Brachycephalus albolineatus* (only AC recorded from the beginning were considered). Note the individual variation. The number of pulses of each note can be observed in Table 2. Abbreviation: MHNCI = Museu de História Natural Capão da Imbuia.

Figure 3. Example of an entire advertisement call and also notes of other advertisement calls of *Brachycephalus albolineatus*. A) Entire advertisement call (MHNCI 006; individual collected and housed at MHNCI 10296). B, D, F) All examples observed of isolated notes, with one pulse (B: MHNCI 008), two pulses (D = MHNCI 022), and three pulses (F = MHNCI 026). C, E, G) Examples of note groups, with 3–3 pulses (C: MHNCI 026), 3–2 pulses (E = MHNCI 027; individual collected and housed at MNRJ 90349), and 2–3 pulses (G = MHNCI 026). Abbreviations: MHNCI = Museu de História Natural Capão da Imbuia; MNRJ = Museu Nacional, Rio de Janeiro. Spectrograms produced with an FFT size of 4096 points, Hann.
window, and overlap of 90% in A and FFT 128 points, Hann window, and overlap of 90% in B–G.

Table 2 (on next page)

Distribution of the number of pulses per note (separated by “,”) along the advertisement calls (AC) of *Brachycephalus albolineatus* (see features 10 and 11 in Fig. 1).

Pulses per note groups are indicated between parenthesis, but indicating separately by “–” the number of pulses in each particular note of the group (see Figs. 1 and 3).
Table 2. Distribution of the number of pulses per note (separated by “,”) along the advertisement calls (AC) of *Brachycephalus albolineatus* (see features 10 and 11 in Fig. 1). Pulses per note groups are indicated between parenthesis, but indicating separately by “-” the number of pulses in each particular note of the group (see Figs. 1 and 3).

| N of individuals (call-voucher deposit number) | Number of pulses per note | Number of isolated notes we hear being emitted before recording the AC |
|-----------------------------------------------|---------------------------|-------------------------------------------------------------------------------------------------|
| 1 (MHNCI 001)                                | 1, 2, 2, 2, 2–3, 3, 3, 3, 3, 3, 3, 3, 3, (3–3), (3–3), (3–3) | 0                                                                                           |

| “Highest sound pressure” (dB)  | ?–? (110 ± 5.6) | [?/17]         |            |             |               |
| Approach (sensu Köhler et al. 2017) | note-centered | call-centered | note-centered | note-centered | not applicable |
| Source                         | This study   | Garey et al. (2012) | Condez et al. (2014) | Guimarães et al. (2017) | Pombal Jr., Sazima & Haddad (1994) | Goutte et al. (2017) | Araújo et al. (2012) | Tandel et al. (2014) | Goutte et al. (2017) | Verdade et al. (2008) | Condez et al. (2016) |

1. Represents note duration under note-centered approach.
2. Note-centered approach and call-centered approach probably mixed in this measurement.
3. The unit of measure was erroneously cited as Hz.
4. Feature cited as “peak frequency” by Guimarães et al. (2017) but refers to our dominant frequency.
5. We are not sure if in the measurement was not mixed with note dominant frequency.
6. The measurement procedure has not been explained and data may be not comparable.
7. Feature cited as “dominant frequency” by Guimarães et al. (2017).
