Abstract

Although mixed extensions of finite games always admit equilibria, this
is not the case for countable games, the best-known example being Wald’s
pick-the-larger-integer game. Several authors have provided conditions for the
existence of equilibria in infinite games. These conditions are typically of topo-
logical nature and are not applicable to countable games. Here we establish
an existence result for the equilibrium of countable games when the strategy
sets are a countable group and the payoffs are functions of the group operation.
In order to obtain the existence of equilibria, finitely additive mixed strategies
have to be allowed. This creates a problem of selection of a product measure of
mixed strategies. We propose a family of such selections and prove existence of
an equilibrium that does not depend on the selection. As a byproduct we show

*Supported by Swiss SNF Sinergia project CRSI22-130435
that if finitely additive mixed strategies are allowed, then Wald’s game admits an equilibrium.

Keywords and phrases: Amenable groups, infinite games, existence of equilibria, invariant means, Wald game.

1 Introduction

In his celebrated theorem Nash (1950, 1951) used fixed point theorems to prove that any finite game admits an equilibrium in mixed strategies. The result fails in general if the strategy sets are not finite. Several authors have provided conditions under which even infinite games admit an equilibrium. Among them Debreu (1952), who assumed convexity and compactness of the strategy sets and continuity and quasi-concavity of the payoffs, and Glicksberg (1952), who assumed compactness of the strategy sets and continuity of the payoff functions. The same year Fan (1952) extended Kakutani’s fixed point theorem, this way permitting a generalization of Nash’s existence theorem like the one in Glicksberg (1952).

One stream of literature considered existence theorems under various conditions that allow discontinuous payoff functions: see, e.g. Dasgupta and Maskin (1986), Simon (1987), Simon and Zame (1990), Reny (1999), Carmona (2005, 2010), Barelli and Soza (2010), papers in Carmona (2011), and references therein.

Wald (1945) considered the case where the strategy set of either one or both players is countable and showed that the mixed extension of a game has a value if one of the strategy sets is finite, but in general it doesn’t if they are both countable.

One way to overcome the lack of equilibria in some games is to enlarge the set of mixed strategy by including also finitely additive probability measures. For the probabilistic and decision-theoretical foundations of the use of finitely additive probability measures, we refer the reader to de Finetti (1970, 1972, 2008), and Savage (1972). Dubins and Savage (1976) used finitely additive measures extensively in their approach to gambling.

The main issue along this road is that in general a mixed extension is not well defined. Given two measures $\mu_1, \mu_2$ on the power sets of $S_1$ and $S_2$, respectively, a product measure $\mu_1 \otimes \mu_2$ is uniquely defined only on the algebra generated by the cylinders and can be extended in a non-unique way to the power set of $S_1 \times S_2$. As a consequence, Fubini’s theorem cannot be applied to this situation and in general the order of integration of a double integral matters.

To obviate this drawback several solutions were proposed in the framework of zero-sum two-person games. Both Yanovskaya (1970) and Kindler (1983) defined the expected value of the payoff to be an arbitrary fixed value, whenever Fubini’s theorem cannot be used, and proved this way the existence of a value for the game. Heath
and Sudderth (1972) instead proved the existence of a value by selecting the product measure that corresponds to a fixed order of integration. Schervish and Seidenfeld (1996) used an approach, whose generalization we follow in our paper, that selects as product measure a convex combination of the measures obtained by interchanging the order of integration. In order to obtain the existence of a value they need the condition that, in their words, there exist some maxmin $\mu_1$-strategy where each good $\mu_2$-reply to $\mu_1$ is close to one of some finite collections of $\mu_2$.

Finitely additive mixed strategies have been used by Maitra and Sudderth (1993, 1998) in the framework of zero-sum stochastic games. Cotter (1991) considered finitely additive strategies in correlated equilibria; Stinchcombe (2011) showed the limitation of his approach and proposed an alternative one.

Marinacci (1997) proved the existence of Nash equilibria in finitely additive mixed strategies under purely measure-theoretic conditions and connected this to the existence of $\varepsilon$-equilibria with countably additive mixed strategies. His analysis needs to restrict attention to payoff functions that are measurable with respect to the algebra generated by the cylinders.

Harris, Stinchcombe, and Zame (2005) dealt with a class of games called nearly compact and continuous and proved existence of equilibria for any game in this class via a continuous compact imbedding in a larger game. They showed the use and limitations of finitely additive mixed strategies for these games.

Stinchcombe (2005) devoted his attention to games that are not nearly compact and continuous and considered several classes of equilibria for these games showing advantages of disadvantages for each of them. The use of finitely additive strategies is fundamental in his analysis.

Capraro and Morrison (2011) proved existence of equilibria for a family of zero-sum two-person games on semigroups when feasible mixed strategies are restricted to a suitable subclass of the class of finitely additive probability measures.

In this paper we prove an existence result for Nash equilibria of countable games by imposing some algebraic conditions on the payoff functions. The strategy set of each player is assumed to be a countable group and the payoff functions depend on their arguments only through the group operation. No topological condition is required. We allow finitely additive mixed strategies defined on the power set of the group. As mentioned before, this requires some care since the product of finitely additive measures is not uniquely defined on the power set of the Cartesian product of the groups, but only on the algebra generated by the cylinders. Since we want to integrate payoff functions that are not measurable with respect to this algebra, we need to select a suitable extension of the product measure. We propose a natural class of extensions by considering an average over all possible orders of integration. We show that the equilibrium exists and it does not depend on the way we choose this average. We characterize the equilibrium strategies and prove that they are the invariant means over the group that solve a suitable variational problem. The equilibrium payoffs have a very simple form. We decided to restrict our attention to countable groups to
avoid drowning our result in a sea of measure-theoretic technicalities.

The paper is organized as follows. Section 2 describes the model and states the main result. Section 3 proves a variational principle that is of interest per se and is used in the proof of the main result. Section 4 contains the proof of the main result. Section 5 examines some interesting generalizations. Section 6 considers several examples.

2 Group games

2.1 Finite games

Consider the classical matching pennies game

\[
\begin{array}{cc}
A & B \\
\hline
A & -1, 1 \\
B & 1, -1 \\
\end{array}
\]

We know that the unique equilibrium of this game is the profile of mixed strategies \((1/2, 1/2), (1/2, 1/2))\).

Notice that the matching pennies game can be re-written as follows. Make the set \(\{A, B\}\) a finite group\(^1\) by endowing it with the binary operation \(*\) defined as

\[
A * A = B * B = B, \quad A * B = B * A = A.
\]

Define \(\phi : \{A, B\} \rightarrow \mathbb{R}\) as follows:

\[
\phi(x) = \begin{cases} 
1 & \text{for } x = A, \\
-1 & \text{for } x = B.
\end{cases}
\]

Consider a game played by players 1 and 2, where each player’s pure strategy set is \(\{A, B\}\) and the payoffs are

\[
u_1(x, y) = -u_2(x, y) = \phi(x * y), \quad \text{for } x, y \in \{A, B\}.
\]

The game that we just described is nothing else than the matching pennies game defined in (2.1).

This suggests the following generalization. Consider a finite group \((G, *)\) and \(N\) functions \(\phi_1, \ldots, \phi_N : G \rightarrow \mathbb{R}\). Given a set of players \(P = \{1, \ldots, N\}\), for \(i \in P\) let \(u_i : G^N \rightarrow \mathbb{R}\) be defined as

\[
u_i(x_1, \ldots, x_N) = \phi_i(x_1 * \cdots * x_N). \tag{2.2}
\]

\(^1\)A set \(G\) with a binary operation \(*\) is called a group if the operation is associative, it has a unit element, and every element has an inverse. If the operation is commutative, then the group is called abelian.
For $\phi := (\phi_1, \ldots, \phi_N)$, call $G(P, G, \phi)$ the game where the set of players is $P$, each player’s set of pure strategies is $G$, and player $i$’s payoff function is given by (2.2). Call $\mathcal{P}(G)$ the set of all probability measures on $2^G$. A probability measure $\lambda \in \mathcal{P}(G)$ is invariant if for all $x, y \in G$ we have $\lambda(x) = \lambda(x * y)$. Observe that finite groups have a unique invariant measure, that is, the uniform measure. We will see in the next sections that a countable group may have many invariant measures.

**Proposition 2.1.** The game $G(P, G, \phi)$ admits an equilibrium in mixed strategies $(\lambda, \ldots, \lambda)$, with $\lambda$ invariant on $G$.

**Proof.** For $\mu_1, \ldots, \mu_N \in \mathcal{P}(G)$, define

$$u_i(\mu_1, \ldots, \mu_N) = \sum_{x_1 \in G} \cdots \sum_{x_N \in G} u_i(x_1, \ldots, x_N) \mu_1(x_1) \cdots \mu_N(x_N).$$

Then we have to prove that for all $i \in P$ and all $\mu_i \in \mathcal{P}(G)$ we have

$$u_i(\lambda, \ldots, \lambda) \geq u_i(\lambda, \ldots, \lambda, \mu_i, \lambda, \ldots, \lambda). \quad (2.3)$$

Notice that, by definition of $u_i$, for all $j \in P$, for all $x_1, \ldots, x_{j-1}, x_{j+1}, \ldots, x_N \in G$ we have

$$\sum_{x_j \in G} u_i(x_1, \ldots, x_j, \ldots, x_N) \lambda(x_j) = \sum_{x_j \in G} \phi_i(x_1 * \cdots * x_j * \cdots * x_N) \lambda(x_j)$$

$$= \sum_{y_j \in G} \phi_i(y_j) \lambda(x_{j-1}^{-1} * \cdots * x_1^{-1} * y_j * x_N^{-1} * \cdots * x_{j+1}^{-1})$$

$$= \sum_{y_j \in G} \phi_i(y_j) \lambda(y_j),$$

where we used the change of variable $y_j = x_1 * \cdots * x_j * \cdots * x_N$. Hence

$$u_i(\lambda, \ldots, \lambda) = \sum_{x_1 \in G} \cdots \sum_{x_N \in G} \phi_i(x_1 * \cdots * x_N) \lambda(x_1) \cdots \lambda(x_N)$$

$$= \sum_{y_j \in G} \phi_i(y_j) \lambda(y_j)$$

$$= \sum_{x_1 \in G} \cdots \sum_{x_i \in G} \cdots \sum_{x_N \in G} \phi_i(x_1 * \cdots * x_N) \lambda(x_1) \cdots \mu_i(x_i) \cdots \lambda(x_N)$$

$$= u_i(\lambda, \ldots, \lambda, \mu_i, \lambda, \ldots, \lambda),$$

that is, (2.3) holds. \qed

In the rest of the paper we will find conditions for the existence of equilibria in countable games, that, among other things, allow to extend Proposition 2.1 to the case of countable strategy sets.
2.2 Countable games

Given a set of players $P = \{1, \ldots, N\}$, a countable set $S$ and bounded functions $u_i : S^N \to [0, 1]$, $i \in P$, consider a game $G = \langle P, S, (u_i)_{i \in P} \rangle$, where $S$ is the strategy set of all players, and $u_i$ is the payoff function of player $i$.

As mentioned in the Introduction, existence of mixed equilibria may fail if only countable mixed strategies are allowed. Therefore we consider a mixed extension of the game $G$ where the space of mixed strategies is $\mathcal{P}(S)$, the space of all finitely additive probability measures on $S$. When doing this, a selection problem immediately arises. Given $\mu_1, \ldots, \mu_N \in \mathcal{P}(S)$, a product measure $\otimes_{i=1}^N \mu_i$ is uniquely defined only on the algebra generated by the cylinders $S \times \cdots \times S \times A \times S \times \cdots \times S$, for all $A \subset S$. This product measure can be (non-uniquely) extended to the power set $2^{S \times \cdots \times S}$. Different extensions correspond to different values of the expected payoff $\int_{S \times \cdots \times S} u \, d \otimes_{i=1}^N \mu_i$.

Here we consider a parametric class of possible extensions that has the advantage of being easily computable. Its simpler bivariate version has been used for zero-sum two-person games by Schervish and Seidenfeld (1996). Call $\Sigma(P)$ the space of permutations of $P$. Let $\nu \in \mathcal{P}(\Sigma(P))$ and $\mu_1, \ldots, \mu_N \in \mathcal{P}(S)$. For $i \in P$, let $u_i : S^N \to [0, 1]$. Define

\[
\begin{align*}
\forall \nu \in \Sigma(P), \mu_1, \ldots, \mu_N \\
\quad u_i^\nu(\mu_1, \ldots, \mu_N) := \sum_{\pi \in \Sigma(P)} \nu(\pi) \int_S \cdots \int_S u_i(x_1, \ldots, x_N) \, d\mu_{\pi(1)}(x_{\pi(1)}) \cdots d\mu_{\pi(N)}(x_{\pi(N)}).
\end{align*}
\]

(2.4)

This clearly defines an extension $\mu_1 \boxtimes_\nu \cdots \boxtimes_\nu \mu_N$ of $\otimes_{i=1}^N \mu_i$ to $2^{S \times \cdots \times S}$ as follows. For $A \subset S \times \cdots \times S$

\[
\begin{align*}
\mu_1 \boxtimes_\nu \cdots \boxtimes_\nu \mu_N(A) &= \sum_{\pi \in \Sigma(P)} \nu(\pi) \int_S \cdots \int_S 1_A(x_1, \ldots, x_N) \, d\mu_{\pi(1)}(x_{\pi(1)}) \cdots d\mu_{\pi(N)}(x_{\pi(N)}),
\end{align*}
\]

(2.5)

where $1_A$ is the indicator function of the set $A$.

For properties of integration with respect to finitely additive measures we refer the reader to Hildebrandt (1934), Dunford and Schwartz (1988), de Finetti (1972), and Bhaskara Rao and Bhaskara Rao (1983). Since every bounded function on a countable set is integrable with respect to any finitely additive probability measure, we do not need any measure-theoretical assumption.

We can now state our main theorem. Let $(G, *)$ be a countable group and given $\phi_1, \ldots, \phi_N : G \to [0, 1]$, define

\[
\begin{align*}
u_i(s_1, \ldots, s_N) = \phi_i(s_1 \ast \cdots \ast s_N).
\end{align*}
\]

(2.6)

For $\phi = (\phi_1, \ldots, \phi_N)$ call $\mathcal{G}(P, S, \phi, \nu)$ the mixed extension of the game $G$ when $u_i$ is defined as in (2.6) and the product measure of the finitely additive mixed strategies is selected as in (2.5).

**Theorem 2.2.** If $(G, *)$ is a countable abelian group, then the game $\mathcal{G}(P, G, \phi, \nu)$ admits a Nash equilibrium that does not depend on $\nu$. 

6
A more general version of Theorem 2.2 will be proved in Section 4.

3 A variational principle for FC-groups

In this section we prove a preliminary result that has some interest per se since it represents a new variational principle for a useful class of groups that we now define.

Definition 3.1. A countable group $G$ is called an FC-group if for all $g \in G$, the conjugacy class $\{h \ast g \ast h^{-1} : h \in G\}$ is finite.

FC-groups have been introduced by Baer (1948) and Neumann (1951). Among others, abelian groups are FC, since every conjugacy class is a singleton.

Let $G$ be a countable group, $A \subset G$ and $g \in G$. Fix the following notation

$$g \ast A = \{g \ast a : a \in A\} \quad A \ast g = \{a \ast g : a \in A\}.$$ 

Definition 3.2. A finitely additive probability measure $\mu$ on the power set of $G$ is called

- left-invariant mean, if $\mu(A) = \mu(g \ast A)$, for all $g \in G$ and $A \subset G$, 
- right-invariant mean, if $\mu(A) = \mu(A \ast g)$, for all $g \in G$ and $A \subset G$, 
- invariant mean, if it is both left- and right-invariant.

For a given countable group $G$, we call $\mathcal{L}(G)$, $\mathcal{R}(G)$ and $\mathcal{I}(G)$ the class of all left-invariant, right-invariant and invariant means on $G$, respectively.

It is well-known that the existence of a left-invariant mean is equivalent to the existence of a right-invariant mean, that is equivalent to the existence of an invariant mean$^2$.

Definition 3.3. A countable group is called amenable if it admits a left-invariant mean.

Amenable groups have been introduced by von Neumann (1929) in relation to the Tarski paradox and they form a hugely studied class of groups still nowadays. Every finite group is amenable, just taking the uniform measure; abelian groups are amenable by a standard but non-trivial argument making use of the Markov-Kakutani

---

$^2$Indeed, given a left-invariant mean $\lambda$, one can define a right-invariant mean $\rho$ by setting $\rho(A) = \lambda(A^{-1})$, where $A^{-1} = \{a^{-1} : a \in A\}$. Now one can define an invariant mean $\mu$ by the formula $\mu(A) = \int_{G} \lambda(A \ast g^{-1}) \, d\rho(g)$. 

7
fixed point theorem. The simplest example of a non-amenable group is the free group on two generators.\(^3\)

We use the following Theorem, appeared in Paterson (1979, Theorem 3.2).

**Theorem 3.4.** Let $G$ be a countable amenable FC-group. Then

$$\mathcal{R}(G) = \mathcal{L}(G) = \mathcal{I}(G).$$

This means that we have no distinctions between left- and right-invariant means.

Given a countable amenable group $G$, $\ell^\infty(G)$ denotes the Banach space of all bounded real-valued function on $G$. The main result of this section is the following variational principle.

**Theorem 3.5.** If $G$ is a countable amenable FC-group and $f : G \to [0, 1]$, then for all $\pi \in \Sigma(P)$ and all $\lambda_2, \ldots, \lambda_N \in \mathcal{I}(G)$ the functional $\Psi : \mathcal{P}(G) \to \mathbb{R}$ defined as

$$\Psi(\mu) = \int \cdots \int f(x_1 \cdots x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)})$$

attains its maximum at some $\lambda \in \mathcal{I}(G)$.

**Remark 3.6.** The space $\mathcal{P}(G)$ is compact in the weak* topology since it is a closed subset of the unit ball of the dual of $\ell^\infty(G)$. Nevertheless the existence of the maximum for the functional $\Psi$ is not automatic, since it is not continuous. To see this take $G = \mathbb{Z}$, $N = 2$, and consider the functional

$$\Psi(\mu) := \int \int 1_N(x + y) \, d\mu(x) \, d\lambda(y),$$

with $\lambda \in \mathcal{I}(\mathbb{Z})$ such that $\lambda(\mathbb{N}) = 1$. Call $\mu_\alpha$ a net of probability measures having finite support in $-\mathbb{N}$ and converging to some $\mu \in \mathcal{I}(\mathbb{Z})$. Observe that $\mu(\mathbb{N}) = 0$. If $\Psi$ were continuous we would have

$$\Psi(\mu) = \lim_\alpha \Psi(\mu_\alpha). \quad (3.1)$$

But

$$\Psi(\mu) = \int \int 1_N(x + y) \, d\mu(x) \, d\lambda(y) = 0,$$

$$\Psi(\mu_\alpha) = \int \int 1_N(x + y) \, d\mu_\alpha(x) \, d\lambda(y)$$

$$= \int \int 1_N(x + y) \, d\lambda(y) \, d\mu_\alpha(x) = 1 \quad \text{for all } \alpha,$$

which contradicts (3.1).

\(^3\)The free group on two generators, say $x$ and $y$, is the group of all words in the letters $x, x^{-1}, y, y^{-1}$, equipped with the operation of concatenation of words, where only the simplifications $x \ast x^{-1} = x^{-1} \ast x = y \ast y^{-1} = y^{-1} \ast y = e$ are allowed, being $e$ the empty word. It was observed by von Neumann himself that this group, usually denoted by $\mathbb{F}_2$, is not amenable. A celebrated example of Ol’sanskiĭ shows the existence of non-amenable groups which do not contain $\mathbb{F}_2$ (see Ol’sanskiĭ, 1980).
Denote

\[ I(f) = \left\{ \int f(x) \, d\lambda(x) : \lambda \in \mathcal{I}(G) \right\}. \]

The following lemma is folklore and follows from the fact that the class \( \mathcal{I}(G) \) is convex and weak*-compact, when seen as a subset of the dual of \( \ell^\infty(G) \).

**Lemma 3.7.** The set \( I(f) \subset \mathbb{R} \) is convex and compact.

This lemma guarantees that the following number is well defined.

\[ I(f)^+ := \max I(f). \quad (3.2) \]

**Lemma 3.8.** Let \( G \) be a countable amenable FC-group and \( f : G \to [0, 1] \). If there exist \( \mu \in \mathcal{P}(G) \) and \( L \in \mathbb{R} \) such that either

\[ \int f(x \ast y) \, d\mu(x) \geq L \quad \text{for all } y \in G, \quad (3.3) \]

or

\[ \int f(y \ast x) \, d\mu(x) \geq L \quad \text{for all } y \in G, \quad (3.4) \]

then there exists \( \lambda \in \mathcal{I}(G) \) such that \( \int f(x) \, d\lambda(x) \geq L \).

Given a set \( A \), its cardinality is denoted by \( |A| \).

**Definition 3.9.** A sequence \( F_n \) of finite subsets of \( G \) is called a left-Følner sequence for \( G \) if for all \( g \in G \) one has

\[ \lim_{n \to \infty} \frac{|(g \ast F_n) \triangle F_n|}{|F_n|} = 0 \]

and a right-Følner sequence for \( G \) if for all \( g \in G \) one has

\[ \lim_{n \to \infty} \frac{|(F_n \ast g) \triangle F_n|}{|F_n|} = 0, \]

where \( \triangle \) stands for the symmetric difference of sets; i.e. \( A\triangle B = (A \cup B) \setminus (A \cap B) = (A \setminus B) \cup (B \setminus A) \).

Følner (1955) proved that such sequences exist for all countable amenable groups.

**Proof of Lemma 3.8.** Let \( F_n \) be a left-Følner sequence for \( G \). Consider the sequence of measures \( \mu_n \) defined by

\[ \mu_n(A) = \frac{1}{|F_n|} \sum_{g \in F_n} \mu(A \ast g) \]
and let $\lambda$ be any weak* limit of (a subnet $\mu_c(\alpha)$ of) this sequence. First we prove that $\lambda \in \mathcal{I}(G)$. Indeed, for all $A \subset G$ and for all $h \in G$, one has

$$|\lambda(A * h) - \lambda(A)| = \lim_{\alpha} |\mu_c(\alpha)(A * h) - \mu_c(\alpha)(A)|$$

$$= \lim_{\alpha} \left| \sum_{g \in F_c(\alpha)} \frac{1}{|F_c(\alpha)|} \left( \mu_c(\alpha)(A * h * g) - \mu_c(\alpha)(A * g) \right) \right|.$$

Observe that the terms that are not in $(h * F_c(\alpha)) \Delta F_c(\alpha)$ cancel out. Majorizing with 1 each of the remaining terms, we get

$$|\lambda(A * h) - \lambda(A)| \leq \lim_{\alpha} \left| (h * F_c(\alpha)) \Delta F_c(\alpha) \right| = 0,$$

which proves that $\lambda \in \mathcal{I}(G)$. Theorem 3.4 implies that $\lambda \in \mathcal{I}(G)$. Now we prove that if (3.3) holds, then $\int f(x) \ d\lambda(x) \geq L$. Indeed, we have

$$\int f(x) \ d\lambda(x) = \lim_{\alpha} \int f(x) \ d\mu_c(\alpha)(x)$$

$$= \lim_{\alpha} \int \frac{1}{|F_c(\alpha)|} \sum_{g \in F_c(\alpha)} f(x) \ d\mu(x * g)$$

$$= \lim_{\alpha} \int \frac{1}{|F_c(\alpha)|} \sum_{g \in F_c(\alpha)} f(x * g^{-1}) \ d\mu(x)$$

$$\geq L.$$

where the inequality stems from the hypothesis that each of the $|F_c(\alpha)|$ summands is larger or equal $L$. The proof for the case (3.4) is similar.

Given a group $G$ we call $G^N$ the direct product of $G$, $N$ times, endowed with the component-wise operation, still denoted by $*$, with a little abuse of notation. If $G$ is amenable, then $G^N$ is amenable, too (Day, 1957). Furthermore, a simple computation shows that if $G$ is an FC-group, then also $G^N$ is an FC-group.

Lemma 3.10. Under the hypotheses of Theorem 3.4

$$\max \left\{ \int f(x_1 * \cdots * x_N) \ d\sigma(x_1, \ldots, x_N) : \sigma \in \mathcal{I}(G^N) \right\} = I(f)^+, \quad (3.5)$$

where $I(f)^+$ is defined as in (3.2).
Proof. For
\[ \psi(x_1, \ldots, x_N) = f(x_1 \ast \cdots \ast x_N) \] (3.6)
define the set
\[ \mathbb{R} \ni \Lambda(\psi) = \left\{ \int \psi(x_1, \ldots, x_N) \, d\sigma(x_1, \ldots, x_N) : \sigma \in \mathcal{I}(G^N) \right\} \]
and call \( L = \max \Lambda(\psi) \), which exists by Lemma 3.7. We have to prove that \( L = I(f)^+ \).

Proof of the inequality \( L \geq I(f)^+ \). By Lemma 3.7 there exists \( \lambda \in \mathcal{I}(G) \) such that \( \int f(x) \, d\lambda(x) = I(f)^+ \). Let \( \lambda^\otimes N \) denote the measure on \( G^N \) defined by the functional
\[ \ell^\infty(G^N) \ni \gamma \mapsto \int \ldots \int \gamma(x_1, \ldots, x_N) \, d\lambda(x_1) \ldots d\lambda(x_N). \]
First we show that \( \lambda^\otimes N \in \mathcal{I}(G^N) \). Indeed for all \( \gamma \in \ell^\infty(G^N) \) and for all \((g_1, \ldots, g_N) \in G^N\) we have
\[
\int \gamma(g_1, \ldots, g_N) \ast (x_1, \ldots, x_N)) \, d\lambda^\otimes N(x_1, \ldots, x_N)
= \int \gamma(g_1 \ast x_1, \ldots, g_N \ast x_N) \, d\lambda^\otimes N(x_1, \ldots, x_N)
= \int \ldots \int \gamma(g_1 \ast x_1, \ldots, g_N \ast x_N) \, d\lambda(x_1) \ldots d\lambda(x_N)
= \int \ldots \int \gamma(x_1, g_2 \ast x_2, \ldots, g_N \ast x_N) \, d\lambda(x_1) \ldots d\lambda(x_N)
= \int \ldots \int \gamma(x_1, x_2, g_3 \ast x_3, \ldots, g_N \ast x_N) \, d\lambda(x_1) \ldots d\lambda(x_N)
\vdots
= \int \ldots \int \gamma(x_1, \ldots, x_N) \, d\lambda(x_1) \ldots d\lambda(x_N),
\]
where the third equality stems from the fact that \( \lambda \) is a left invariant mean, therefore
\[
\int \gamma(g_1 \ast x_1, \ldots, g_N \ast x_N) \, d\lambda(x_1) = \int \gamma(x_1, g_2 \ast x_2, \ldots, g_N \ast x_N) \, d\lambda(x_1).
\]
For the forth equality define \( \zeta(x_2, \ldots, x_N) = \int \gamma(x_1, x_2, \ldots, x_N) \, d\lambda(x_1) \). Then, since \( \lambda \) is a left invariant mean, we have
\[
\int \zeta(g_2 \ast x_2, g_3 \ast x_3, \ldots, g_N \ast x_N) \, d\lambda(x_2) = \int \zeta(x_2, g_3 \ast x_3, \ldots, g_N \ast x_N) \, d\lambda(x_2),
\]
i.e.,

\[
\int \int \gamma(x_1, g_2 \ast x_2, g_3 \ast x_3, \ldots, g_N \ast x_N) \, d\lambda(x_1) \, d\lambda(x_2) \\
= \int \int \gamma(x_1, x_2, g_3 \ast x_3, \ldots, g_N \ast x_N) \, d\lambda(x_1) \, d\lambda(x_2).
\]

The remaining equalities are obtained analogously. We have then shown that \(\lambda^{\otimes N} \in \mathcal{L}(G^N)\). By Theorem 3.4 applied to the FC-group \(G^N\) it follows that \(\lambda^{\otimes N} \in \mathcal{I}(G^N)\).

Now we show that \(\int f(x_1 \ast \ldots \ast x_N) \, d\lambda^{\otimes N}(x_1, \ldots, x_N) = I(f)^+\). We have

\[
\int f(x_1 \ast \ldots \ast x_N) \, d\lambda^{\otimes N}(x_1, \ldots, x_N) = \int \ldots \int f(x_1 \ast \ldots \ast x_N) \, d\lambda(x_1) \ldots d\lambda(x_N) \\
= \int \ldots \int f(x_1) \, d\lambda(x_1) \ldots d\lambda(x_N) \\
= \int \ldots \int I(f)^+ \, d\lambda(x_2) \ldots d\lambda(x_N) \\
= I(f)^+.
\]

This shows that \(I(f)^+ \in \Lambda(\psi)\) and therefore \(I(f)^+ \leq L\).

**Proof of the inequality** \(L \leq I(f)^+\). Let \(\bar{\sigma} \in \mathcal{I}(G^N)\) be such that

\[
\int f(x_1 \ast \ldots \ast x_N) \, d\bar{\sigma}(x_1, \ldots, x_N) = L
\]

(such a measure exists by Lemma 3.7 applied to the group \(G^N\) and to the function \(\psi(x_1, \ldots, x_N) = f(x_1 \ast \ldots \ast x_N)\)) and let \(\sigma_\alpha\) be a net of countably additive probability measures on \(G^N\) converging to \(\bar{\sigma}\) in the weak* topology. Define a countably additive probability measure \(\mu_\alpha\) on \(G\) by setting for all \(x_1 \in G\)

\[
\mu_\alpha(x_1) = \sum_{(x_2, \ldots, x_N) \in G^{N-1}} \sigma_\alpha(x_1 \ast (x_2 \ast \ldots \ast x_N)^{-1}, x_2, \ldots, x_N).
\]

To show that this is indeed a countably additive probability measure notice that for each \(x_1 \in G\) we have \(\mu_\alpha(x_1) \geq 0\) and therefore it suffices to show that \(\sum_{x_1 \in G} \mu_\alpha(x_1) = 1\). This follows from the observation that \(\mu_\alpha(x_1) = \sigma_\alpha(A_{x_1})\), where

\[A_{x_1} = \{(x_1 \ast (x_2 \ast \ldots \ast x_N)^{-1}, x_2, \ldots, x_N) : (x_2, \ldots, x_N) \in G^{N-1}\}\]

and the fibers \(A_{x_1}\) form a partition of \(G^N\).
Now, let $\mu$ be any weak* limit of a subnet, denoted by $\mu_\beta$, of the net $\mu_\alpha$. For any $g \in G$, one has

$$\int_G f(g \ast x_1) \, d\mu(x_1) = \lim_\beta \int_G f(g \ast x_1) \, d\mu_\beta(x_1)$$

$$= \lim_\beta \sum_{x_1 \in G} f(g \ast x_1) \mu_\beta(x_1)$$

$$= \lim_\beta \sum_{x_1 \in G} \sum_{x_2, \ldots, x_N \in G^{-1}} f(g \ast x_1) \sigma_\beta(x_1 \ast (x_2 \ast \cdots \ast x_N)^{-1}, x_2, \ldots, x_N)$$

$$= \lim_\beta \sum_{(x_2, \ldots, x_N) \in G^{-1}} \sum_{x_1 \in G} f(g \ast x_1) \sigma_\beta(x_1 \ast (x_2 \ast \cdots \ast x_N)^{-1}, x_2, \ldots, x_N)$$

where in the last equality we put $z = x_1 \ast (x_2 \ast \cdots \ast x_N)^{-1}$. Observe that in the forth equality we can exchange the order of summation since the series are nonnegative and convergent. For the same reason we can now replace $G \ast (x_2 \ast \cdots \ast x_N)^{-1}$ with $G$ (the mapping $x \mapsto x \ast (x_2 \ast \cdots \ast x_N)^{-1}$ is a permutation). Therefore, using again (3.6), we have

$$\lim_\beta \sum_{(x_2, \ldots, x_N) \in G^{-1}} \sum_{z \in G^*(x_2 \ast \cdots \ast x_N)^{-1}} f(g \ast z \ast x_2 \ast \cdots \ast x_N) \sigma_\beta(z, x_2, \ldots, x_N)$$

$$= \lim_\beta \sum_{(x_2, \ldots, x_N) \in G^N} f(g \ast z \ast x_2 \ast \cdots \ast x_N) \sigma_\beta(z, x_2, \ldots, x_N)$$

$$= \lim_\beta \int f(g \ast z \ast x_2 \ast \cdots \ast x_N) \, d\sigma_\beta(z, x_2, \ldots, x_N)$$

$$= \lim_\beta \int \psi((g, 1_G, \ldots, 1_G) \ast (z, x_2, \ldots, x_N)) \, d\sigma_\beta(z, x_2, \ldots, x_N)$$

$$= \int \psi((g, 1_G, \ldots, 1_G) \ast (z, x_2, \ldots, x_N)) \, d\sigma(z, x_2, \ldots, x_N)$$

$$= \int \psi(z, x_2, \ldots, x_N) \, d\sigma(z, x_2, \ldots, x_N)$$

$$= \int f(z \ast x_2 \ast \cdots \ast x_N) \, d\sigma(z, x_2, \ldots, x_N)$$

$$= L.$$

We have proved that $\int_G f(g \ast x_1) \, d\mu(x_1) = L$ for all $g \in G$. Therefore, by Lemma 3.8, there exists $\lambda \in \mathcal{F}(G)$ such that $\int f(x) \, d\lambda(x) \geq L$. It follows that $I(f)^+ \geq L$. \qed
Proof of Theorem 3.5. Call \( \mathbf{\lambda} = (\lambda_2, \ldots, \lambda_N) \) and
\[
S_{\mathbf{\lambda}, \pi} = \sup_{\mu \in \mathcal{P}(G)} \left\{ \int \cdots \int f(x_1 \cdots x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)}) \right\}.
\]

(3.7)

By Lemma 3.7, we know that \( S_{\mathbf{\lambda}, \pi} \geq I(f)^+ \), for all \( \mathbf{\lambda} \) and \( \pi \). We recall that the value \( I(f)^+ \) is attained, basically by definition, by an invariant mean. So it suffices to show that \( S_{\mathbf{\lambda}, \pi} = I(f)^+ \). Now, by contradiction, suppose that there exist \( \mu \in \mathcal{P}(G) \) and \( \lambda_2, \ldots, \lambda_N \in \mathcal{I}(G) \) such that
\[
\int \cdots \int f(x_1 \cdots x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)}) =: L > I(f)^+.
\]

Call \( \sigma \) the measure on \( G^N \) defined by the functional
\[
\ell^\infty(G^N) \ni \gamma \mapsto \int_{G^N} \gamma(x_1, \ldots, x_N) \, d\sigma(x_1, \ldots, x_N)
\]
\[
= \int \cdots \int \gamma(x_1, \ldots, x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)}).
\]

Define \( \psi(x_1, \ldots, x_N) = f(x_1 \cdots x_N) \). We start considering the case \( \pi(1) < N \). Setting \( \pi(1) = j \), for any \( (g_1, \ldots, g_N) \in G^N \) we have
\[
\int \psi((x_1, \ldots, x_N) \ast (g_1, \ldots, g_N)) \, d\sigma(x_1, \ldots, x_N)
\]
\[
= \int \psi((x_1 \ast g_1, \ldots, g_N \ast x_N)) \, d\sigma(x_1, \ldots, x_N)
\]
\[
= \int \cdots \int f(x_1 \ast g_1 \ast x_2 \ast g_2 \cdots x_N \ast g_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)})
\]
\[
= \int \cdots \int f(x_1 \ast x_2 \ast \cdots \ast x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)})
\]
\[
= L,
\]

where the third equality can be shown by setting
\[
\xi(x_1, \ldots, x_{j-1}, x_{j+1}, \ldots, x_N) = \int f(x_1 \cdots x_N) \, d\mu(x_j)
\]
and noticing that
\[
\int \cdots \int f(x_1 \ast g_1 \ast \cdots \ast x_j \ast g_j \ast x_{j+1} \ast g_{j+1} \ast \cdots \ast x_N \ast g_N) \, d\mu(x_j) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)})
\]
\[
= \int \cdots \int \xi(x_1 \ast g_1, x_{j-1} \ast g_{j-1}, x_j \ast g_{j+1}, x_{j+2} \ast g_{j+2}, \ldots, x_N \ast g_N) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)})
\]
\[
= \int \cdots \int \int f(x_1 \ast x_2 \ast \cdots \ast x_N) \, d\mu(x_{\pi(1)}) \, d\lambda_2(x_{\pi(2)}) \cdots d\lambda_N(x_{\pi(N)}).
\]

Therefore, we can apply Lemma 3.8 to the amenable FC-group \(G^N\) and to the function \(\psi(x_1, \ldots, x_N)\). This means that there exists an invariant measure \(\rho' \in \mathcal{I}(G^N)\) such that \(\int f(x_1 \ast \cdots \ast x_N) \, d\rho'(x_1, \ldots, x_N) \geq L > I(f)^+\). This contradicts Lemma 3.10.

If \(\pi(1) = N\), then the result can be proved replacing (3.8) with
\[
\int \psi((g_1, \ldots, g_N) \ast (x_1, \ldots, x_N)) \, d\sigma(x_1, \ldots, x_N)
\]
and following the steps of the previous case.

\[\square\]

4 Proof of the main result

As before, \(G\) is a countable amenable FC-group and, for \(i \in P\), let \(\phi_i : G \to [0, 1]\) and \(\overline{\lambda}_i \in \mathcal{I}(G)\) be such that
\[
\int \phi_i \, d\overline{\lambda}_1 = I(\phi_i)^+.
\]

Every abelian group is an amenable FC-group, hence Theorem 2.2 is a corollary of the following more general result.

**Theorem 4.1.** If \(G\) is a countable amenable FC-group, then the profile of strategies \((\overline{\lambda}_1, \ldots, \overline{\lambda}_N)\) is a Nash equilibrium for the game \(\mathcal{G}(P, G, \phi, \nu)\).

**Proof.** We have to prove that for all \(i \in P\) and all \(\mu_i \in \mathcal{P}(G)\) we have
\[
u_i(\overline{\lambda}_1, \ldots, \overline{\lambda}_{i-1}, \mu_i, \overline{\lambda}_{i+1}, \ldots, \overline{\lambda}_N).
\]

Using (2.4), we know that
\[
u_i(\overline{\lambda}_1, \ldots, \overline{\lambda}_N) = \sum_{\pi \in \Sigma(P)} \nu(\pi) \int_G \cdots \int_G u_i(x_1, \ldots, x_N) \, d\overline{\lambda}_{\pi(1)}(x_{\pi(1)}) \cdots d\overline{\lambda}_{\pi(N)}(x_{\pi(N)}).
\]
where $u_i(x_1, \ldots, x_N) = \phi_i(x_1 \ast \cdots \ast x_N)$. Since all $\overline{\lambda}_j$ are invariant, each of the summands of $u''_i(\overline{\lambda}_1, \ldots, \overline{\lambda}_i, \ldots, \overline{\lambda}_N)$ is equal to the corresponding summand for $u'_i(\overline{\lambda}_1, \ldots, \overline{\lambda}_{i-1}, \mu_i, \overline{\lambda}_{i+1}, \ldots, \overline{\lambda}_N)$, except when $\pi(1) = i$. If we call $\Sigma_i(P)$ the class of all permutations of $P$ such that $\pi(1) = i$, then all we have to prove is

$$
\sum_{\pi \in \Sigma_i(P)} \nu(\pi) \int_G \ldots \int_G u_i(x_1, \ldots, x_N) \ d\overline{\lambda}_i(x_i) \ d\overline{\lambda}_{\pi(2)}(x_{\pi(2)}) \ldots \ d\overline{\lambda}_{\pi(N)}(x_{\pi(N)}) \\
\geq \sum_{\pi \in \Sigma_i(P)} \nu(\pi) \int_G \ldots \int_G u_i(x_1, \ldots, x_N) \ d\mu_i(x_i) \ d\overline{\lambda}_{\pi(2)}(x_{\pi(2)}) \ldots \ d\overline{\lambda}_{\pi(N)}(x_{\pi(N)}).
$$

This inequality can be shown to hold summand by summand using Theorem 3.5. \(\square\)

5 Some generalizations

Here we consider some generalizations of Theorem 4.1. The first extension allows us to show the existence of an equilibrium in Wald’s game, a classical example of countable game that does not admit equilibria in $\sigma$-additive mixed strategies.

5.1 Transformations of group operations

Let $\eta_1, \ldots, \eta_N : G \to G$ be bijections and let

$$u''_i(x_1, \ldots, x_N) = \phi_i(\eta_1(x_1) \ast \cdots \ast \eta_N(x_N)) \quad \text{for } i \in P. \quad (5.1)$$

For $\eta = (\eta_1, \ldots, \eta_N)$ call $\mathcal{G}(P, G, \phi, \eta, \nu)$ the game where the payoffs are given by the mixed extensions of (5.1), as in (2.4).

Theorem 5.1. If $G$ is a countable amenable FC-group, then the game $\mathcal{G}(P, G, \phi, \eta, \nu)$ admits a Nash equilibrium.

Proof. Call

$$u_i(y_1, \ldots, y_N) = \phi_i(y_1 \ast \cdots \ast y_N).$$

By Theorem 4.1 we know that the game $\mathcal{G}(P, G, \phi, \nu)$ admits a Nash equilibrium given by $(\overline{\lambda}_1, \ldots, \overline{\lambda}_N)$. Therefore if we define for $i \in P$ a measure $\rho_i$ on $2^G$ as follows

$$\rho_i(A) = \overline{\lambda}_i(\eta_i(A)),$$

then the profile $(\rho_1, \ldots, \rho_N)$ is a Nash equilibrium of $\mathcal{G}(P, G, \phi, \eta, \nu). \quad \square$
5.2 Graph games

For every \( i \in P \) let \( P_i \subset P \) be such that \( i \in P_i \) and \( |P_i| \geq 2 \). Imagine that players are nodes of a directed graph and think of \( P_i \) as the neighbors of player \( i \) (including \( i \) herself). Consider functions \( \phi_i : G \to [0, 1] \) such that

\[
u_i(x_1, \ldots, x_N) = \phi_i(*)_{j \in P_i} x_j,
\]

that is, the payoff of player \( i \) depends only on the strategies of her neighbors.

Call \( P = (P_1, \ldots, P_N) \) and define the game \( \mathcal{G}(P, P, G, \phi, \nu) \) where the payoff functions are as in (5.2).

**Theorem 5.2.** If \( G \) is a countable amenable FC-group, then the game \( \mathcal{G}(P, P, G, \phi, \nu) \) admits a Nash equilibrium.

The proof of this theorem follows the line of the proof of Theorem 4.1 and is therefore omitted.

6 Examples

6.1 Games on \( \mathbb{Z} \)

As the next proposition shows, when the game is played on \( \mathbb{Z} \), the equilibrium of Theorem 4.1 has an interesting structure, that is, each equilibrium strategy has its mass either entirely adherent to \(-\infty\) or to \(+\infty\), or if it is split between the two, then it can be split in any possible way.

**Proposition 6.1.** Consider a game \( \mathcal{G}(P, \mathbb{Z}, \phi, \nu) \). Let \( (\lambda_1, \ldots, \lambda_N) \) be an equilibrium for this game, where \( \lambda_1, \ldots, \lambda_N \in \mathcal{I}(\mathbb{Z}) \). Then, for all \( i \in P \), one of the following three possibilities is true

(a) \( \lambda_i(\mathbb{N}) = 0 \),
(b) \( \lambda_i(\mathbb{N}) = 1 \),
(c) if \( 0 < \lambda_i(\mathbb{N}) < 1 \), then for any \( \delta \in [0, 1] \) there exists another equilibrium strategy \( \lambda_i' \in \mathcal{I}(\mathbb{Z}) \) with \( \lambda_i'(\mathbb{N}) = \delta \).

**Proof.** Assume that neither (a) nor (b) holds. We prove that (c) must be true. Suppose that \( \lambda_i \in \mathcal{I}(\mathbb{Z}) \) is an equilibrium strategy for player \( i \) and \( \lambda_i(-\mathbb{N}) = \theta \in (0, 1) \). Call

\[
K = \int \phi_i \, d\lambda_i, \quad \theta K_1 = \int \phi_i \, d\lambda_i, \quad (1 - \theta) K_2 = \int \phi_i(x) \, d\lambda_i.
\]

Then

\[
K = \theta K_1 + (1 - \theta) K_2.
\]
Assume that $K_2 > K_1$. Consider now a measure $\lambda_i' \in \mathcal{I}(\mathbb{Z})$ such that $\lambda_i'(-N) = 0$ and for $A \subset \mathbb{N}$ we have $\lambda_i'(A) = (1 - \theta)^{-1} \lambda_i(A)$. Then
\[
\int \phi_i \, d\lambda_i' = K_2 > K,
\]
which, by Theorem 4.1, contradicts the fact that $\lambda_i$ is an equilibrium strategy. A similar argument holds if $K_1 > K_2$.

It is easy to see that if $K_1 = K_2$, then any measure $\lambda_i''$ such that for $0 < \kappa < \theta^{-1}$
\[
\begin{align*}
\lambda_i''(A) &= \kappa \lambda_i(A) \quad \text{for } A \subset -\mathbb{N}, \\
\lambda_i''(A) &= (1 - \theta \kappa)(1 - \theta)^{-1} \lambda_i(A) \quad \text{for } A \subset \mathbb{N},
\end{align*}
\]
satisfies $\int \phi_i \, d\lambda_i'' = K$ and therefore is an equilibrium strategy. This proves part (c). \qed

**Example 6.2** (Matching pennies). Consider the following countable version of matching pennies. The strategy set of each of the two players is $\mathbb{Z}$ and the payoff functions are
\[
u_1(x, y) = 1 - \nu_2(x, y) = 1_{2\mathbb{Z}}(x + y),
\]
where $k\mathbb{Z}$ is the set of multiples of $k$. This game is equivalent to the one where players choose only Odd or Even and player 1 wins if both players make the same choice. Any profile of strategies $(\mu_1, \mu_2)$ such that $\mu_1(2\mathbb{Z}) = \mu_2(2\mathbb{Z}) = 1/2$ is an equilibrium of the game.

The game can be generalized as follows. Consider a partition $A_1, \ldots, A_N$ of $\mathbb{Z}$ and payoff functions
\[
u_i(x_1, \ldots, x_N) = 1_{A_i}(x_1 + \cdots + x_N).
\]
If for each $i \in P$ the measure
\[
\overline{\lambda}_i \in \arg \max_{\lambda_i \in \mathcal{I}(\mathbb{Z})} \lambda_i(A_i),
\]
then, by Theorem 4.1, the profile $(\overline{\lambda}_1, \ldots, \overline{\lambda}_N)$ is a Nash equilibrium of the game.

Notice that, if all sets $A_1, \ldots, A_N$ are periodic (not necessarily with the same period), then for all $\lambda, \lambda' \in \mathcal{I}(\mathbb{Z})$ we have
\[
\lambda(A_i) = \lambda'(A_i),
\]
Therefore any profile of invariant measures is an equilibrium. Let $m$ be the lowest common multiple of the periods $m_i$ of the $A_i$’s.

Consider now the $m$ congruence classes $m\mathbb{Z} + k$. Any profile of probability measures $(\mu_1, \ldots, \mu_N)$ such that for $i \in P$ and $k \in \{0, \ldots, m - 1\}$
\[
\mu_i(m\mathbb{Z} + k) = \overline{\lambda}_i(m\mathbb{Z} + k) = 1/m
\]
is an equilibrium, too.

18
Example 6.3 (Wald’s game). Wald (1945) introduced the following game as a counterexample to the existence of minmax in zero-sum two-person games when the sets of strategies for both players are infinite. Let the strategy set be $\mathbb{Z}$ and

$$u_1(x, y) = 1 - u_2(x, y) = \begin{cases} 1 & \text{if } x > y, \\ 1/2 & \text{if } x = y, \\ 0 & \text{if } x < y. \end{cases}$$

Call $z := -y$; then the payoff function becomes

$$u_1(x, z) = \begin{cases} 1 & \text{if } x + z > 0, \\ 1/2 & \text{if } x + z = 0, \\ 0 & \text{if } x + z < 0. \end{cases}$$

Applying Theorem 5.1 we obtain the equilibrium $(\lambda, \rho)$ with $\lambda, \rho \in \mathcal{I}(\mathbb{Z})$ and $\lambda(\mathbb{N}) = \rho(-\mathbb{N}) = 1$. This shows the striking difference between countably additive and finitely additive extensions of countable games.

6.2 Games on $\mathbb{Z}^2$

Consider a two-person game where the strategy sets of both players are $\mathbb{Z}^2$ and the payoff function $u_i$ is

$$u_i(x + y) = \mathbbm{1}_{C_i}(x + y),$$

(6.1)

where $C_i$ is some open cone, i.e., $C_i$ is an open subset of $\mathbb{R}^2$ such that if $x \in C_i$, then $\beta x \in C_i$ for all $\beta \in \mathbb{R}_+$. 

Proposition 6.4. Let $\phi_i = \mathbbm{1}_{C_i}$. If $\overline{\lambda}_i \in \mathcal{I}(\mathbb{Z}^2)$ and $\overline{\lambda}_i(C_i) = 1$ for all $i \in P$, then the profile $(\overline{\lambda}_1, \ldots, \overline{\lambda}_N)$ is an equilibrium of the game $\mathcal{G}(P, \mathbb{Z}^2, \phi, \nu)$.

Proof. By Theorem 4.1 a measure $\overline{\lambda}_i$ is an equilibrium strategy if

$$\overline{\lambda}_i = \arg \max_{\lambda_i \in \mathcal{I}(\mathbb{Z}^2)} \lambda_i(C_i).$$

Since $\lambda_i(C_i) \leq 1$ all we need to prove is that for each open cone $C_i$ there exists a measure $\overline{\lambda}_i$ such that $\overline{\lambda}_i(C_i) = 1$. This is achieved by using Følner sequences as follows. For every open cone $C_i$ there exists a convex open cone $C_i^* \subset C_i$. We now prove the existence of $\overline{\lambda}_i$ such that $\overline{\lambda}_i(C_i^*) = 1$. Call $Q_n := \{-n, \ldots, n\}^2 \subset \mathbb{Z}^2$ and $F_n := Q_n \cap C_i^*$. 

Claim 6.5. The sequence $F_n$ is a Følner sequence.

Proof of Claim 6.5. We need to prove that for all $g \in \mathbb{Z}^2$ we have

$$\lim_{n \to \infty} \frac{|(g * F_n) \triangle F_n|}{|F_n|} = 0.$$
There exists $\delta > 0$ such that for $n$ large enough $|F_n| > \delta n^2$. Moreover if $g = (g_1, g_2)$, then $|(g * F_n) \triangle F_n| \leq g_1 g_2 n$. This proves the Claim. \[ \Box \]

Define a probability measure $\mu_n$ on $2^{\mathbb{Z}^2}$ as follows:

$$\mu_n(A) = \frac{|A \cap F_n|}{|F_n|}.$$ 

Call $\bar{\lambda}_i$ a weak* limit of a subnet $\mu_{c(\alpha)}$ of $\mu_n$. First we prove that $\bar{\lambda}_i \in I(Z^2)$. For all $A \subset \mathbb{Z}^2$ and for all $g \in \mathbb{Z}^2$

$$|\bar{\lambda}_i(A + g) - \bar{\lambda}_i(A)| = \lim_{\alpha} \left| \frac{|(A + g) \cap F_{c(\alpha)}|}{|F_{c(\alpha)}|} - \frac{|A \cap F_{c(\alpha)}|}{|F_{c(\alpha)}|} \right|$$

$$= \lim_{\alpha} \left| \frac{|A \cap (F_{c(\alpha)} - g)|}{|F_{c(\alpha)}|} - \frac{|A \cap F_{c(\alpha)}|}{|F_{c(\alpha)}|} \right|$$

$$\leq \lim_{\alpha} \left| \frac{|A \cap ((F_{c(\alpha)} - g) \triangle F_{c(\alpha)})|}{|F_{c(\alpha)}|} \right|$$

$$= 0,$$

where the inequality is due to the fact that

$$A \cap ((F_{c(\alpha)} - g) \setminus (A \cap F_{c(\alpha)})) \subset A \cap ((F_{c(\alpha)} - g) \triangle F_{c(\alpha)}).$$

Then we prove that $\bar{\lambda}_i(C_i^*) = 1$. Indeed

$$\bar{\lambda}_i(C_i^*) = \lim_{\alpha} \frac{|C_i^* \cap F_{c(\alpha)}|}{|F_{c(\alpha)}|}.$$ 

Since $F_{c(\alpha)} \subset C_i^*$ for all $\alpha$, we have

$$\frac{|C_i^* \cap F_{c(\alpha)}|}{|F_{c(\alpha)}|} = 1 \quad \text{for all } \alpha. \quad \Box$$

### 6.3 Games on $\mathbb{Q} \cap [0,1] \mod 1$

Take $G = \mathbb{Q} \cap [0,1]$ equipped with the sum modulo 1. Then $G$ is a countable abelian group, so it is an amenable FC-group. Observe that any invariant mean $\lambda$ on $G$ satisfies the following property. With an abuse of language we use the symbol $[a, b]$ to denote the set $\{x \in G : a \leq x \leq b\}$.

**Proposition 6.6.** For every $\lambda \in \mathcal{F}(G)$ and every $a, b \in [0,1]$, $a < b$, we have $\lambda([a,b]) = b - a$. 

20
Proof. Observe that, by invariance, for every \( n \in \mathbb{N} \)
\[
\lambda \left( \left[ 0, \frac{1}{n} \right] \right) = \lambda \left( \left[ \frac{1}{n}, \frac{2}{n} \right] \right) = \cdots = \lambda \left( \left[ \frac{n-1}{n}, 1 \right] \right) = \frac{1}{n}.
\]
Hence, by finite additivity, if \( a = k/n \) and \( b = m/n \), then
\[
\lambda([a,b]) = \lambda \left( \left[ \frac{k}{n}, \frac{m}{n} \right] \right) = \frac{m-k}{n}.
\]
Therefore any two invariant means on \( G \) coincide on the algebra generated by intervals in \( G \), but they can be extended in many different ways to \( 2^G \).

**Proposition 6.7.** Call \( c \) the cardinality of \( \mathbb{R} \). Then \( |\mathcal{J}(G)| \geq 2^c \).

Proof. If \( G \) is endowed with the discrete topology, then it is a locally compact group, whose Haar measure is the counting measure. It follows that the set of essentially (with respect to the Haar measure) bounded real-valued functions on \( G \) is equal to \( \ell^\infty(G) \). Therefore Chou (1970, Theorem on page 444) can be used to get the result.

Consider now a game on \( G \) where for \( i \in P \),
\[
\phi_i(x) = 1_{A_i}(x).
\]
If \( A_1, \ldots, A_N \) are in the algebra generated by intervals, then the every profile \( (\lambda_1, \ldots, \lambda_N) \), with \( \lambda_i \in \mathcal{J}(G) \) is an equilibrium. Otherwise the equilibrium strategy for player \( i \) is
\[
\overline{\lambda}_i \in \arg \max_{\lambda \in \mathcal{J}(G)} \lambda(A_i).
\]

7 Conclusions

We have considered a class of games where the strategy sets are a countable group and the payoff functions depend on the strategies only through the group operation. We have shown that finitely additive equilibria exist for this class of games. We have not used any topological conditions, just the algebraic structure of the payoffs. The only measure theoretical assumption in our paper refers to the selection of the product of finitely additive mixed strategies.

Even if the algebraic condition that we use leaves out a huge set of games, it includes cases that are not covered by Marinacci (1997). In fact in general the payoff functions that we considered are not measurable with respect to the algebra generated by the cylinders. Indeed, his payoff functions satisfy Fubini’s theorem (Marinacci, 1997, Proposition 3), whereas ours in general do not.
As (Stinchcombe, 2005, Example 2.1) shows, the games that we considered in
general are not nearly compact and continuous as the ones in Harris et al. (2005).
Stinchcombe (2005) proves very general deep existence results, that are typically
non-constructive. In our paper we characterize the equilibrium strategies in a simple
form.
Capraro and Morrison (2011) prove that invariant means are minmax strategies
for zero-sum two-person games when the set of allowed strategies is restricted so that
the exchange of the order of integration is possible. In our paper we do not put any
restriction on the set of mixed strategies. Our results are not only more general, they
also requires different tools for their proof.

Acknowledgments

The authors thank Marco Dall’Aglio for sparking their interest in group games,
Patrizia Berti and Pietro Rigo for their useful comments about finitely additive prob-
ability measures, and Alain Valette for helpful discussions about amenability.
