Abstract: The genus *Cheirogaleus*, the dwarf lemurs (Infraorder Lemuriformes), has been identified as harboring cryptic species diversity. More comprehensive fieldwork combined with improvements in genetic research has revealed a larger radiation of species than was initially described in a number of lemur genera, including *Avahi*, *Lepilemur*, *Microcebus*, and *Mirza*. Available genetic and morphological evidence suggests that *Cheirogaleus* is among the genera where diversity was previously underestimated, and additional fieldwork may reveal even more species. A population of *Cheirogaleus* from northern Madagascar in and around Montagne d’Ambre National Park, surveyed during an expedition in 2005, was recently identified and proposed as a new species. Additional specimens were obtained during fieldwork in February of 2015. Subsequent genetic and morphological analyses of the data collected have determined that this population is an independent lineage, and herein we describe this new species, which we name *Cheirogaleus andysabini* after New York philanthropist Andy Sabin.

Key Words: *Cheirogaleus*, cryptic species, dwarf lemurs, Madagascar, new species

Introduction

The dwarf lemurs (genus *Cheirogaleus*) are a radiation of small, arboreal primates endemic to the island of Madagascar (Mittermeier *et al*. 2010). The taxonomy and species status in *Cheirogaleus* has been contentious; a situation exacerbated by the limited number of specimens available for study in collections (Schwarz 1931; Groves 2000; Lei *et al*. 2014). Groves (2000) recognized seven *Cheirogaleus* species (*C. major*, *C. medius*, *C. crossleyi*, *C. adipicaudatus*, *C. sibreei*, *C. ravan*, and *C. minuscus*); a number that has been challenged as overly conservative in recent fieldwork and genetic analyses, suggesting a larger radiation in this genus (Hapke *et al*. 2005; Groeneveld *et al*. 2009, 2010; Thiele *et al*. 2013; Lei *et al*. 2014).

Concerns about overenthusiastic species descriptions in the lemuriform radiation raised by Tattersall (2007, 2013) have been addressed previously in Lei *et al*. (2014). Application of the Phylogenetic Species Concept and access to data from molecular technology (Eldredge and Cracraft 1980; Wheeler and Platnick 2000) has nearly tripled the number of recognized lemur species since the early 1980s (36 to >103; Tattersall 1982; Mittermeier *et al*. 2010). *Cheirogaleus* has not experienced the type of genus-level expansion seen in *Lepilemur* (Louis *et al*. 2006) or *Microcebus* (Mittermeier *et al*. 2010); genera with the greatest increases in recognized species diversity. Nevertheless, *Cheirogaleus* appears to be harboring greater diversity than previously suspected (Thiele *et al*. 2013; Lei *et al*. 2014).

A new species of *Cheirogaleus* was identified via extensive fieldwork in and around Montagne d’Ambre National Park (Fig. 1) in November of 2005 (Lei *et al*. 2014), with additional fieldwork in February of 2015. The massif of Montagne d’Ambre is of volcanic origin (Segalen 1956), and this rain forest ecotype may have been separated from the surrounding dry deciduous vegetation for millions of years (Raxworthy and Nussbaum 1994), with the last volcanic eruptions occurring as recently as 2 mya (DuPuy and Moat 1996). It has a distinctive microclimate that is in part the result of greater than average precipitation in comparison to the surrounding areas. Raxworthy and Nussbaum (1994) noted the presence of species there that were altitudinal specialists, with those above 900 m living in moist rainforest, and those below 900 m living in a transitional area with a dry deciduous forest. Montagne d’Ambre’s combination of geology and climate has resulted in a unique community of microendemic fauna and flora; plants (Mathieu 2003; Callmander *et al*. 2004, 2005); genera with the greatest increases in recognized species diversity. Nevertheless, *Cheirogaleus* appears to be harboring greater diversity than previously suspected (Thiele *et al*. 2013; Lei *et al*. 2014).

A new species of *Cheirogaleus* was identified via extensive fieldwork in and around Montagne d’Ambre National Park (Fig. 1) in November of 2005 (Lei *et al*. 2014), with additional fieldwork in February of 2015. The massif of Montagne d’Ambre is of volcanic origin (Segalen 1956), and this rain forest ecotype may have been separated from the surrounding dry deciduous vegetation for millions of years (Raxworthy and Nussbaum 1994), with the last volcanic eruptions occurring as recently as 2 mya (DuPuy and Moat 1996). It has a distinctive microclimate that is in part the result of greater than average precipitation in comparison to the surrounding areas. Raxworthy and Nussbaum (1994) noted the presence of species there that were altitudinal specialists, with those above 900 m living in moist rainforest, and those below 900 m living in a transitional area with a dry deciduous forest. Montagne d’Ambre’s combination of geology and climate has resulted in a unique community of microendemic fauna and flora; plants (Mathieu 2003; Callmander *et al*. 2004, 2005).
Lei et al. (2009), amphibians (D’Cruze et al. 2010; Rakotoarison et al. 2015), reptiles (Raxworthy and Nussbaum 1994; D’Cruze et al. 2008; Glaw et al. 2009; Ratsoavina et al. 2011), birds (Wilmé 1996), and mammals (Louis et al. 2008; Goodman et al. 2015).

The first herpetological survey in the area of Montagne d’Ambre was carried out in 1893, and subsequent expeditions have cataloged the regional endemism of the park and surrounding area (D’Cruze et al. 2008). The national park and surrounding region continues to be an exciting source of new species, including a chameleon in the genus Furcifer (Glaw et al. 2009). The area is also home to a number of lemurs, including two species in the genus Eulemur (E. coronatus and E. sanfordi), the Montagne d’Ambre fork-marked lemur (Phaner electromontis), the aye-aye (Daubentonia madagascariensis), and the recently described Montagne d’Ambre mouse lemur (Microcebus arnholdi Louis et al., 2008). Malagasy endemic carnivores are also found in the park, including the rare falanouc (Eupleres goudotii) and the ring-tailed mongoose (Galidia elegans) (Mittermeier et al. 2010).

The area around Montagne d’Ambre National Park and the Forêt d’Ambre Special Reserve were initially protected in the 1920’s as a forest station called ‘Les Roussettes’. In 1958, Montagne d’Ambre became the first national park created in Madagascar, and the Forêt d’Ambre S.R. was created the same year (Raxworthy and Nussbaum 1994). Subsequent deforestation has reduced the size of both the national park and the special reserve, in particular impacting the lowland rainforests (those below 900 m). More than twenty years ago, Raxworthy and Nussbaum (1994) observed a noticeable difference in forest cover based on a comparison of aerial photographs from the 1950s and the early 1990s. Ongoing deforestation has since been noted by Glaw and Vences (2007) and D’Cruze et al. (2008), among others.

Montagne d’Ambre National Park, like much of the remaining forested areas of Madagascar, is under the greatest threat from a combination of slash-and-burn agriculture (tavy) and charcoal extraction (Nicoll and Langrand 1989). The growth of the nearby port city of Antsiranana (formerly Diego Suarez) has accelerated deforestation by greatly increasing the demand for charcoal, a primary source of fuel for cooking. The town of Joffreville, named for the French General Joseph Joffre of First World War fame and located just east of the national park, is a center of charcoal extraction. As of 2001, 98% of the population of Joffreville was employed primarily in agriculture, with 90% farming and 8%
Table 1. Free-ranging *Cheirogaleus* samples used in this study. IDs correspond to Figure 2 and Figure 5 (Lei et al. 2014), with the exception of the samples from Thiele et al. 2013 (denoted at the bottom of the table, as well as on the map).

engaged in pastoral activities (predominantly cattle grazing) (Cornell University/USAID/FOFIFA/INSTAT Census 2001). Timber extraction, quarrying, and land clearance for cattle grazing are also threats to the endemic wildlife. These threats have been exacerbated by rapid population growth, low levels of education, and extreme poverty; factors that have led the human population to devastate the ecosystem to obtain needed resources (Gezon and Freed 1999; Marcus and Kull 1999; D’Cruze et al. 2008).

Genetic samples, measurements and photographs of several sedated *Cheirogaleus* individuals were taken prior to their release (Table 2). The samples taken from these animals were subsequently analyzed in the context of a larger phylogenetic study of the genus *Cheirogaleus* by Lei et al. (2014), and determined to be sufficiently distinct to warrant elevation as a new species in the *C. crossleyi* species group. The Montagne d’Ambre individuals were designated *Cheirogaleus* sp. nov. 1 by Lei et al. (2014), as were six other “confirmed candidate species” (CCS) that likely warrant elevation to full species status. Here we describe a new species of dwarf lemur endemic to the area around Montagne d’Ambre.

### Methods

Methods used to identify this new species were presented in Lei et al. (2014). Briefly, extracted genomic DNA taken from safely immobilized animals was subjected to a series of wet bench and computational analyses (Table 2). The mitochondrial regions analyzed were: Cytochrome b (cytb) (Irwin et al. 1991); Cytochrome oxidase subunit II (COII) (Adkins and Honeycutt 1994); the displacement loop or control region (D-loop) (Baker et al. 1993; Wyner et al. 1999); a fragment of the Cytochrome oxidase subunit III gene (COIII); NADH-dehydrogenase sub units 3, 4L, and 4 (ND3, ND4L, and ND4); and the tRNA

A New Species in the Genus Cheirogaleus (Cheirogaleidae)

The mitochondrial combined guide tree included representative populations from the total sample set of Lei et al. (2014), with all individuals sampled at Montagne d’Ambre (Cheirogaleus sp. nov. 1) and all other individuals in the Cheirogaleus crossleyi group (C. crossleyi, CCS2, C. sp. nov. 2). Representatives from the other Cheirogaleus species groups (C. lavasoensis, C. major, C. medius, C. sibreei), as well as Microcebus berthae as an outgroup species, were also included in the bPTP analyses (Fig. 2).

Additionally, D-loop sequences were generated from fecal samples collected in February 2015 from Montagne d’Ambre (locations marked on Fig. 1), which were identical to those from blood and tissue samples. Because of the identical nature of these samples, they were not used in the analyses. The pelage of Cheirogaleus sp. nov. 1 was also compared to closely related species (Figs. 3 and 4).

Results

In the cytb sequence fragment analyses, Cheirogaleus sp. nov. 1, differs from its closest genetic relatives in Lei et al. (2014) (CCS2, CCS3, C. lavasoensis and C. crossleyi) in genetic distance by 5.6%±0.7%, 6.3%±0.7%, 8.1%±0.8% and 6.2%±0.6%, respectively. Despite being relatively geographically close to CCS6, with the Irodo River as a barrier, C. sp. nov. 1 is distinct from CCS6. The latter is clustered in the “Medius” subgroup clade with a genetic distance of 11.7%±0.9% between C. sp. nov. 1 and CCS6. Additional analyses using the mitochondrial loci listed in the Methods section above resulted in C. sp. nov. 1 segregating as an independent lineage with a high degree of confidence, but the results with nuclear loci were less robust among lineages even when large geographic distances (up to 900 km) were a factor. This may be the result of a number of factors, including incomplete lineage sorting, ancient introgression, or the small size of the nuclear sample analyzed (Lei et al. 2014, Fig. 5, Appendix I b–Ic). The mitochondrial and nuclear phylogenetic trees generated in this study are available in Lei et al. (2014, Figs. 2-6, Appendix Ia-Ic).

The population aggregate analysis (PAA) results were congruent with those presented in Lei et al. (2014). We obtained a Bayesian PTP support value of 1.00 indicating an excellent probability of the likelihood that this lineage is an independent species based on the given mitochondrial dataset (Fig. 2).

Discussion

Sufficient mitochondrial genetic divergence was observed, in conjunction with differences in pelage, to warrant elevation of this population as a new species. Additional evidence used in elevating this population to species status was its geographic isolation from other populations of Cheirogaleus. Cheirogaleus sp. nov. 1 is found northwest of the Irodo River, and is isolated from other Cheirogaleus species by this boundary (Fig. 5). A similar geographical situation exists with the Montagne d’Ambre mouse lemur (Microcebus arnholdi) and the Tavaratra mouse lemur (Microcebus tavaratra), with the Irodo River acting as a barrier between the two lineages; pelage differences are visible between these two Microcebus species as well (Mittermeier et al. 2010). Geographic

![Figure 2. Results of the Bayesian species delimitation analyses of the combined mitochondrial dataset using the bPTP webserver (http://species.h-its.org). A total of 100,000 Markov Chain Monte Carlo generations were run with a rooted tree including the outgroup species Microcebus berthae. The Montagne d’Ambre population, site designation AMB (Cheirogaleus sp. nov. 1), had robust support (1.00) as an independent lineage within the C. crossleyi group.](https://bioone.org/journals/Primate-Conservation/44/2/47/download)

*Juvenile

Figure 3. Illustrations of *Cheirogaleus* lineages based on archived photographs (Museum of Texas Tech University; Fig. 8 in Lei et al. 2014). Left panel represents all *Cheirogaleus* lineages, except *C. sibreei*. Right panel represents the *Cheirogaleus* crossleyi group, including *Cheirogaleus* sp. nov. 1, here named *Cheirogaleus andysabini*.
A New Species in the Genus *Cheirogaleus* (Cheirogaleidae)

**Figure 4.** Illustration of *Cheirogaleus andysabini* and photographs of Omaha’s Henry Doorly Zoo and Aquarium (OHDZA) catalogue acronym for specimen DAMB15.4 taken at Montagne d’Ambre. Illustrations by Stephen D. Nash ©Conservation International. Photographs by Edward E. Louis, Jr.
Figure 5. Map of Madagascar with the ranges of Cheirogaleus sp. nov. 1 (Cheirogaleus andysabini) and closely related Cheirogaleus species highlighted to show the geographic distance between lineages. ID numbers on the map correspond to ID numbers of animals listed in Table 1. Photographs of Cheirogaleus sp. nov. 1 and CCS6 (Lei et al. 2014), the Ankaranana/Andrafiamena/Analamera/Bekaraoka lineage is provided to show a clear difference in pelage and the distance between the ranges of the two lineages. The Irodo River acts as a northern barrier to CCS6.
A New Species in the Genus *Cheirogaleus* (Cheirogaleidae)

of whole blood; stored and curated at the Museum of Texas Tech University (MTTU, catalog number: TTU-M 118801/K 129239) Genetic Resources Collection, Natural Sciences Research Laboratory (NSRL); We placed a microchip subcutaneously between the scapulae and recorded as 4669753C7D; Collected by Jean Freddy Ranaivoarisoa, Ravaka Ramana-mahefa, Nirina Jean de Dieu Andriamadison, Joseph Désiré Rabekinaja, Gérard Nalanirina, François Randrianasolo on 22 November 2005.

Paratypes: AMB5.28-5.32, 5.34-5.35, DAMB 15.4-15.6

Other specimens: Possible (unconfirmed), Harvard Museum of Comparative Zoology (MCZH) 44951, skull and skin from Montagne d’Ambre accessioned in January 1929 as part of the Grandidier Collection by Robert Barbour received from Louis Lavauden (missing in inventory since 1994). Additional specimen in the collection of the American Museum of Natural History (AMNH) M-100650, skull and skin taken in November of 1930 by Austin Rand at a site near Montagne d’Ambre “15 miles southwest of Tsarakimbty.”

Type locality: Madagascar: Antsiranana Province, Diana Region, District Antsiranana II, Montagne d’Ambre National Park, S12.52720, E49.17950 at 1073 m above sea level.

Measurements of holotype: Measurements (in cm and g) recorded in a field catalog: Body length 18.2 cm; Tail length 27.1 cm; Head crown 5.8 cm; Mass 310 g.

Description: The dorsum, limbs, and head are a rufous brown. The areas around the orbits are brownish-black, with a white patch proximal to the fleshy part of the nose in the inter-ocular space. The pelage on the ventral surface of the mandible is white, which is continuous onto the white pelage of the ventrum. Size is generally smaller than *C. crossleyi*, braincase higher, with very poorly expressed temporal lines (Fig. 4).

Diagnosis: *Cheirogaleus andysabini* can be distinguished from *C. crossleyi*, CCS2, CCS3 and *C. lavasoensis* by 10, 7, 10 and 16 apomorphic characters in the cytochrome b gene, respectively (Appendix II(k); Lei et al. 2014). *Cheirogaleus andysabini* has four diagnostic sites in the cyt b sequence fragment such as G, A, G and G at the positions of 297, 303, 306 and 1071, respectively, which differentiate *C. andysabini* from all other *Cheirogaleus* species. Despite being geographically close to CCS6, with the Irodo River as a barrier, *C. andysabini* is distinct by nine diagnostic characters from CCS6, which is clustered in the “Medius” subgroup clade. An average weight of 0.282 ±0.61 kg, dark fur around eyes, rufous brown fur on dorsum, limbs, and head, venter is white. Table 3 contains measurements of captured individuals.

Distribution: *Cheirogaleus andysabini* is known from the Montagne d’Ambre National Park and areas nearby around the town of Joffreville, northwest of the Irodo River in northern Madagascar (Fig. 1). Observed at 541–1073 m above sea level.

Etymology: This new species is named after Andy Sabin, a well-known New York philanthropist committed to species conservation, especially turtles, amphibians and primates. In particular, he has supported many projects in Madagascar,
including research on lemurs, tortoises and frogs. His long-term interest, his enthusiasm, and his generosity have helped to encourage many researchers and conservationists, young and old alike.

Vernacular names: Montagne d’Ambre or Andy Sabin’s dwarf lemur.

Acknowledgments

We thank the Madagascar National Parks and Ministere de l’Environnement et de Forêts for sampling permission. We are most grateful to The Ahmanson Foundation, the Theodore F. and Claire M. Hubbard Family Foundation, the Private Action Fund / Conservation International, the Margot Marsh Biodiversity Foundation, and the National Geographic Society, for financial assistance. Colin Groves thanks Eileen Westwig, Judy Chupasko, Larry Heaney, Paula Jenkins, Chris Smeenk, Frieder Meier, and Cecile Callou for access to museum specimens under their care. In particular, thanks go to the Harvard Museum of Comparative Zoology and the American Museum of Natural History for photographs from their collection. We also want to acknowledge the office and field staffs of the Madagascar Biodiversity Partnership for their excellence in collecting the samples from the Cheirogaleus safely, and returning them to their forest habitat. We are most grateful to two reviewers for their insights and helpful suggestions.
