Abstract
It is shown that the series derived by Mizrahi, giving the Husimi transform (or covariant symbol) of an operator product, is absolutely convergent for a large class of operators. In particular, the generalized Liouville equation, describing the time evolution of the Husimi function, is absolutely convergent for a large class of Hamiltonians. By contrast, the series derived by Groenewold, giving the Weyl transform of an operator product, is often only asymptotic, or even undefined. The result is used to derive an alternative way of expressing expectation values in terms of the Husimi function. The advantage of this formula is that it applies in many of the cases where the anti-Husimi transform (or contravariant symbol) is so highly singular that it fails to exist as a tempered distribution.
1. Introduction

A particularly useful and illuminating way of studying the classical limit is to formulate quantum mechanics in terms of phase space distributions [1, 2, 3]. The advantage of such a formulation as compared with the standard Hilbert space formulation is that it puts quantum mechanics into a form which is similar to the probabilistic phase space formulation of classical mechanics. At least from a formal, mathematical point of view it thus allows one to regard quantum mechanics as a kind of generalized version of classical mechanics.

There are, of course, many different phase space formulations of quantum mechanics. The one which was discovered first is the formulation based on the Wigner function [1, 2, 3, 4]. In the case of a system having one degree of freedom with position $\hat{x}$, momentum $\hat{p}$ and density matrix $\hat{\rho}$ the Wigner function is defined by

$$W(x, p) = \frac{1}{2\pi} \int dy e^{ipy} \langle x - y/2 | \hat{\rho} | x + y/2 \rangle$$

(in units chosen such that $\hbar = 1$). The Wigner function continues to find many important applications (in quantum tomography [3], for example). However, if the aim is specifically to represent quantum mechanics in a manner which resembles classical mechanics as closely as possible, then the Wigner function suffers from the serious disadvantage that it is not strictly non-negative (except in special cases [5])—which makes the analogy with the classical phase space probability distribution somewhat strained.

There has accordingly been some interest in the problem of constructing alternative distributions, which are strictly non-negative, and which can be interpreted as probability density functions. There are, in fact, infinitely many such functions [6, 7, 8, 9, 10, 11]. The one which was discovered first, and which is the focus of this paper, is the Husimi, or $Q$-function [1, 2, 3, 12, 13, 14, 15], which is obtained from the Wigner function by smearing it with a Gaussian convolution:

$$Q(x, p) = \frac{1}{\pi} \int dx' dp' \exp \left[ -\left( x - x' \right)^2 - \left( p - p' \right)^2 \right] W(x', p')$$

(in units such that $\hbar = 1$, and where we assume that $x$, $p$ have been made dimensionless by choosing a suitable length scale $\lambda$, and making the replacements $x \to x/\lambda$, $p \to \lambda p$). It should be emphasised that it is not simply that the Husimi function has the mathematical significance of a probability density function. It also has this significance physically. It has been shown that the Husimi function is the probability distribution describing the outcome of a joint measurement of position and momentum in a number of particular cases [3, 8, 17, 18]. More generally it can be shown [19, 20] that the Husimi function has a universal significance: namely, it is the probability density function describing the outcome of any retrodictively optimal joint measurement process. In Appleby [20] it is argued that this means that the Husimi function may be regarded as the canonical quantum mechanical phase space probability distribution, which plays the same role in relation to joint measurements of $x$ and $p$ as does the function $|\langle x | \psi \rangle|^2$ in relation to single measurements of $x$ only.

If one wants to construct a systematic procedure for investigating the transition from quantal to classical it is not enough simply to find an analogue for the classical phase space probability distribution. One also needs an analogue of the classical Liouville equation, giving the time evolution of the probability distribution. In the formulation based on the Husimi function this is accomplished by means of Mizrahi’s formula [15], giving the Husimi transform of an operator product (also see Lee [2], Cohen [21], Prugovečki [22] and O’Connell and Wigner [23]).
Let $A_W$ denote the Weyl transform of the operator $\hat{A}$, defined by

$$A_W(x, p) = \int dy e^{ipy} \langle x - \frac{y}{2} \mid \hat{A} \mid x + \frac{y}{2} \rangle$$

The Husimi transform (or covariant symbol) $A_H$ is then given by

$$A_H(x, p) = \frac{1}{\pi} \int dx' dp' \exp \left[ -\left( x - x' \right)^2 - \left( p - p' \right)^2 \right] A_W(x', p')$$

Mizrahi [15] has derived the following formula for the Husimi transform of the product of two operators $\hat{A}$, $\hat{B}$:

$$(\hat{A} \hat{B})_H = A_H e^{\partial_x^- \partial_p^+} B_H$$

where $\partial_{\pm} = 2^{-1/2}(\partial_x \mp i\partial_p)$. Using this formula, and the fact that the Husimi function is just the Husimi transform of the density matrix scaled by a factor $1/(2\pi)$, it is straightforward to derive the following generalization of the Liouville equation:

$$\frac{\partial}{\partial t} Q = \{H_H, Q\}_H$$

where $H_H$ is the Husimi transform of the Hamiltonian, and $\{H_H, Q\}_H$ is the generalized Poisson bracket

$$\{H_H, Q\}_H = \sum_{n=0}^{\infty} \frac{2}{n!} \text{Im} \left( \partial_x^n H_H \partial_p^n Q \right)$$

The first term in the sum on the right-hand side is just the ordinary Poisson bracket. The remaining terms represent quantum mechanical corrections.

It is not apparent from Mizrahi’s derivation, whether these expressions are exact, or whether they are only asymptotic. In Section 2 we will show that there is a large class of operators for which the series in Eq. (2) and consequently the series in Eq. (4) is absolutely convergent. This property is closely connected with the complex analytic properties of the Husimi transform, as discussed by Mehta and Sudarshan [25] and Appleby [26].

The significance of the result proved in Section 2 is best appreciated if one compares Eqs. (2–4) with the corresponding formulae in the Wigner-Weyl formalism [1, 2, 27, 28, 29]:

$$(\hat{A}\hat{B})_W = A_W \exp \left[ i \frac{1}{2} \left( \partial_x^- \partial_p^+ - \partial_x^+ \partial_p^- \right) \right] B_W$$

$$\frac{\partial}{\partial t} W = \{H_W, W\}_W$$

$$\{H_W, W\}_W = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!2n} H_W \left( \partial_x^- \partial_p^+ - \partial_x^+ \partial_p^- \right)^{2n+1} W$$

where $H_W$ is the Weyl transform of the Hamiltonian, and where $\{H_W, W\}_W$ denotes the Moyal bracket [28].

It can be seen that Eqs (3, 4) and Eqs. (5, 6) are formally very similar. However, this formal resemblance is somewhat deceptive, for it turns out that the two sets of equations have quite different convergence properties.

The formula for the Weyl transform of an operator product, Eq. (5), is exact if either $\hat{A}$ or $\hat{B}$ is a polynomial in $\hat{x}$ and $\hat{p}$ (in which case the series terminates after a finite number of terms). More generally, if $A_W$, $B_W$ are $C^\infty$ functions satisfying appropriate conditions on their growth at infinity, then it can be shown that the series is asymptotic [30]. However, there are many operators of physical interest for which the Weyl transform is only defined in a distributional sense, and for operators
such as this the series can be highly singular. Consider, for example, the parity
operator $\hat{V}$, whose action in the $x$-representation is given by

$$\langle x | \hat{V} | \psi \rangle = \langle -x | \psi \rangle$$

We have

$$V_W(x, p) = \pi \delta(x) \delta(p)$$

Substituting this expression into Eqs. (5) gives

$$(\hat{V}^2)_W(x, p) = \pi^2 \delta(x) \delta(p) \exp \left[ \frac{i}{2} \left( \partial_x \partial_p - \partial_p \partial_x \right) \right] \delta(x) \delta(p)$$

The left-hand side of this equation $= 1$; whereas the expression on the right-hand
side is an infinite sum each individual term of which is ill-defined (being a product
of distributions concentrated at the origin).

Mizrahi’s [15] derivation of the formula for the Husimi transform of an operator
product, Eq. (2), depends on the same kind of formal manipulation that is used
in Groenewold’s [27] derivation of Eq. (5), and so it might be supposed that the
validity of the formula is similarly restricted. However, it turns out that the sum
in Eq. (2) is actually much better behaved. In fact, it will be shown in Section 2
that, subject to certain not very restrictive conditions on the operators $\hat{A}$ and $\hat{B}$,
the sum on the right-hand side of Eq. (2) is not only defined and asymptotic; it is
even absolutely convergent for all $x, p$. This is essentially because $A_H$ is typically
a much less singular object than $A_W$ [due to the Gaussian convolution in Eq. (1)].

In Section 3 we apply the result just described to the problem of expressing
expectation values in terms of the Husimi function.

The expectation value of an operator $\hat{A}$ can be obtained from the Wigner function
using the formula [1, 2]

$$\text{Tr}(\hat{\rho} \hat{A}) = \int dxdp A_W(x, p) W(x, p)$$

In certain cases we can also express the expectation value in terms of the Husimi
function using [1, 2, 15]

$$\text{Tr}(\hat{\rho} \hat{A}) = \int dxdp A_H(x, p) Q(x, p)$$

where $A_{\overline{\Pi}}$ is the anti-Husimi transform (or contravariant symbol) of $\hat{A}$, defined by

$$A_{\overline{\Pi}} = e^{-\partial_x \partial_- A_H}$$

[with $\partial_\pm = 2^{-1/2}(\partial_x \mp i \partial_p)$, as before]. Eq. (8) is valid (for example) whenever $A_W$
exists as a tempered distribution and $Q$ belongs to the corresponding space
of test functions (i.e. the $C^\infty$ functions of rapid decrease). However, we have the
problem that $A_{\overline{\Pi}}$ is often so highly singular that it is not defined as a tempered
distribution—which means that the usefulness of Eq. (8) is somewhat limited. This
is often seen as a serious drawback of the Husimi formalism.

However, it turns out that it is often possible to circumvent this difficulty. Suppose we substitute the series given by Eq. (10) into the right hand side of Eq. (8), and suppose we then reverse the order of sum and integral. This gives

$$\text{Tr}(\hat{\rho} \hat{A}) = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \int dxdp \left( \partial_+^n \partial_-^n A_{\overline{\Pi}}(x, p) \right) Q(x, p)$$

In Section 3 we show that it often happens that the sum on the right-hand side of
this equation is absolutely convergent, even in many of the cases where $A_{\overline{\Pi}}$ fails to
exist as a tempered distribution.
2. CONVERGENCE OF THE PRODUCT FORMULA

We will find it convenient to work in terms of coherent states. Define
\[ \hat{a} = \frac{1}{\sqrt{2}}(\hat{x} + i\hat{p}) \quad \hat{a}^\dagger = \frac{1}{\sqrt{2}}(\hat{x} - i\hat{p}) \]
and let \( \phi_n \) denote the \( n \)th (normalised) eigenstate of the number operator \( \hat{a}^\dagger \hat{a} \):
\[ \hat{a} \phi_0 = 0 \quad \phi_n = \frac{1}{\sqrt{n!}}(\hat{a}^\dagger)^n \phi_0 \]

Let \( \hat{D}_{xp} \) be the displacement operator
\[ \hat{D}_{xp} = e^{i(p\hat{x} - \hat{x}\hat{p})} \]
and define
\[ \phi_{n;xp} = \hat{D}_{xp}\phi_n \quad \phi_{xp} = \phi_{0;xp} \]
The \( \phi_{xp} \) are the coherent states. Let \( \hat{A} \) be any operator (not necessarily bounded) with domain of definition \( \mathcal{D}_{\hat{A}} \), and suppose that \( \phi_{xp} \in \mathcal{D}_{\hat{A}} \) for all \( x, p \). It is then straightforward to show that
\[ A_H(x,p) = \langle \phi_{xp}, \hat{A}\phi_{xp} \rangle \]
(we no longer use the Dirac bra-ket notation, because the existence of \( \langle \psi, \hat{A}\chi \rangle \) does not, in general, imply the existence of \( \langle \hat{A}^\dagger\psi, \chi \rangle \)).

If \( \hat{A}, \hat{B} \) are both bounded then the proof of Eq. (2) is comparatively straightforward. However, we want to make the proof as general as possible. We then have the difficulty that the sum in Eq. (2) will only be defined if \( A_H \) and \( B_H \) are both \( C^\infty \); whereas functions of the form \( \langle \hat{D}_{xp}\psi, \hat{A}\hat{D}_{xp}\psi \rangle \) are, in general, not even once-differentiable, let alone \( C^\infty \). We are thus faced with the question: what conditions must we impose on the operator \( \hat{A} \) in order to ensure that the function \( A_H \) is \( C^\infty \)? One answer to this question is given by the following theorem.

**Theorem 1.** Let \( \mathcal{D}_{\hat{A}}, \mathcal{D}_{\hat{A}}^\dagger \) be the domains of definition of \( \hat{A}, \hat{A}^\dagger \) respectively. Suppose that \( \phi_{xp} \in \mathcal{D}_{\hat{A}} \cap \mathcal{D}_{\hat{A}}^\dagger \) for all \( x, p \). Suppose, also, that \( \langle \phi_{x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle, \langle \phi_{x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) and \( \langle \phi_{1;xp_1}, \hat{A}\phi_{xp_2} \rangle \) are continuous functions on \( \mathbb{R}^4 \). Then \( A_H \) is an analytic function, which uniquely continues to a holomorphic function defined on the whole of \( \mathbb{C}^2 \).

The continuation is given by
\[ A_H(x,p) = \frac{\langle \phi_{x+p}, \hat{A}\phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} \] (12)
where \( x, p \) are arbitrary complex, and where \( x_\pm, p_\pm \) are the real variables defined by
\[ x_\pm = \frac{1}{2}(x + x^*) \pm \frac{i}{2}(p - p^*) \] (13)
\[ p_\pm = \frac{1}{2}(p + p^*) \mp \frac{i}{2}(x - x^*) \] (14)

This theorem is a strengthened version of results proved by Mehta and Sudarshan [25] and Appleby [26]. The proof is given in Appendix A.

It is worth noting that the condition in the statement of this theorem is quite weak. If the three functions listed exist and are continuous then, without making any explicit assumption regarding the differentiability of these functions, it automatically follows that \( A_H \) must be complex analytic.

We also have the following lemma:
Lemma 2. Suppose that $\hat{A}$ satisfies the conditions of Theorem 1. Then

$$\frac{\langle \phi_{n;xp}; \hat{A}\phi_{x,p+} \rangle}{\langle \phi_{x-p, \phi_{x+p+}} \rangle} = \frac{1}{\sqrt{n!}} \sum_{r=0}^{n} \binom{n}{r} (z^*_+ - z^-_+)^{n-r} \frac{\partial^r}{\partial z_+^r} \hat{A} \mathcal{H}(x,p)$$

(15)

$$\frac{\langle \hat{A}^\dagger \phi_{x-p, \phi_{x+p+}} \rangle}{\langle \phi_{x-p, \phi_{x+p+}} \rangle} = \frac{1}{\sqrt{n!}} \sum_{r=0}^{n} \binom{n}{r} (z^-_+ - z^*_+)^{n-r} \frac{\partial^r}{\partial z_+^r} \hat{A} \mathcal{H}(x,p)$$

(16)

where $x_\pm, p_\pm$ are the variables defined by Eqs. (13) and (14), and where $z_\pm = \frac{1}{\sqrt{2}}(x_\pm + ip)$. The proof of this lemma is given in Appendix B.

If $x, p$ are both real (so that $z_- = z_+^*$) Eqs. (15) and (16) become

$$\langle \phi_{n;xp}; \hat{A}\phi_{x,p+} \rangle = \frac{1}{\sqrt{n!}} \partial^n \hat{A} \mathcal{H}(x,p)$$

(17)

$$\langle \hat{A}^\dagger \phi_{x,p}; \phi_{n;xp} \rangle = \frac{1}{\sqrt{n!}} \partial^n \hat{A} \mathcal{H}(x,p)$$

(18)

where

$$\partial_\pm = \frac{\partial}{\partial z_\pm} = \frac{1}{\sqrt{2}} \left( \frac{\partial}{\partial x} \mp i \frac{\partial}{\partial p} \right)$$

Using these results the product formula becomes very straightforward. Let $\hat{A}, \hat{B}$ be any pair of operators satisfying the conditions of Theorem 1. Suppose, also, that $\phi_{xp} \in \mathcal{D}_{\hat{A}\hat{B}}$ for all $x, p \in \mathbb{R}$. Then, for real $x, p$,

$$(\hat{A}\hat{B}) \mathcal{H}(x,p) = \langle \phi_{xp}; \hat{A}\hat{B}\phi_{xp} \rangle = \langle \hat{A}^\dagger \phi_{xp}; \hat{B}\phi_{xp} \rangle = \sum_{n=0}^{\infty} \langle \hat{A}^\dagger \phi_{xp}; \phi_{n;xp} \rangle \langle \phi_{n;xp}; \hat{B}\phi_{xp} \rangle$$

(19)

where we have used the fact that the $\phi_{n;xp}$ constitute an orthonormal basis. The absolute convergence of this sum is an immediate consequence of basic Hilbert space theory. Using Eqs. (17) and (18) we deduce

$$(\hat{A}\hat{B}) \mathcal{H}(x,p) = \sum_{n=0}^{\infty} \frac{1}{n!} \partial^n \hat{A} \mathcal{H}(x,p) \partial^n \hat{B} \mathcal{H}(x,p) = \hat{A} \mathcal{H}(x,p) e^{\hat{B}} \hat{A} \mathcal{H}(x,p)$$

which is the product formula. The absolute convergence of this sum follows from the absolute convergence of the sum in Eq. (19).

3. Expectation Values

We now discuss the implications that the result just proved has for the convergence of Eq. (11), giving the expectation value of $\hat{A}$ in terms of the Husimi function.

Of course, one does not expect the right hand side of Eq. (11) to converge for arbitrary $\hat{A}$ and $\hat{\rho}$—since, apart from anything else, an unbounded operator does not have a well-defined expectation value for every state $\hat{\rho}$. We therefore need to place some kind of restriction on the class of operators $\hat{A}$ and density matrices $\hat{\rho}$ considered. The result we prove is probably not the most general possible. However, it will serve to illustrate the point, that the sum on the right hand side of Eq. (11) is often absolutely convergent, even in many of the cases where the anti-Husimi transform fails to exist as a tempered distribution.
We accordingly confine ourselves to the case of density matrices for which the Husimi function \( Q \in \mathcal{I}(\mathbb{R}^2) \), where \( \mathcal{I}(\mathbb{R}^2) \) is the space of \( C^\infty \) functions which are rapidly decreasing at infinity \[\] (i.e. the space of test functions for the space of tempered distributions). In other words, we assume that

\[
sup_{(x,p) \in \mathbb{R}^2} \left| (1 + x^2 + p^2)^l \partial_x^m \partial_p^n Q(x,p) \right| < \infty
\]

for every triplet of non-negative integers \( l, m, n \).

We assume that \( \hat{A} \) has the properties

1. \( \phi_{xp} \in \mathcal{D}_A \cap \mathcal{D}_{A^*} \) for all \( x, p \in \mathbb{R} \).
2. There exist positive constants \( K_{\pm} \) and non-negative integers \( N_{\pm} \) such that

\[
\| \hat{A} \phi_{xp} \| \leq K_- (1 + x^2 + p^2)^{N_-} \quad (20)
\]

\[
\| \hat{A}^* \phi_{xp} \| \leq K_+ (1 + x^2 + p^2)^{N_+} \quad (21)
\]

for all \( x, p \in \mathbb{R} \).

We will say that an operator satisfying these two conditions is polynomial bounded.

The following lemma gives two properties of such operators which will be needed in the sequel.

**Lemma 3.** Suppose that \( \hat{A} \) is polynomial bounded. Then

1. \( \hat{A} \) satisfies the conditions of Theorem \( \[\] \). In particular, \( A_H \) is analytic.
2. For every pair of non-negative integers \( m, n \) there exists a positive constant \( K_{mn} \) and a non-negative integer \( N_{mn} \) such that

\[
| \partial_x^m \partial_p^n A_H(x,p) | \leq K_{mn}(1 + x^2 + p^2)^{N_{mn}} \quad (22)
\]

for all \( x, p \in \mathbb{R} \).

The proof is given in Appendix \[\].

We now ready to prove the main result of this section.

**Theorem 4.** Suppose that \( \hat{A} \) is polynomially bounded, and suppose that the density matrix \( \hat{\rho} \) is such that the corresponding Husimi function is rapidly decreasing at infinity. Suppose, also, that \( \hat{A} \hat{\rho} \) is of trace-class. Then

\[
\text{Tr}(\hat{A} \hat{\rho}) = \sum_{n=0}^{\infty} \frac{(-1)^n}{n!} \int dx dp \ (\partial_x^n \partial_p^n A_H(x,p)) Q(x,p)
\]

(23)

where the sum on the right hand side is absolutely convergent.

**Proof.** We have

\[
\text{Tr}(\hat{A} \hat{\rho}) = \frac{1}{2\pi} \int dx dp \langle \phi_{xp}, \hat{A} \hat{\rho} \phi_{xp} \rangle
\]

\[
= \frac{1}{2\pi} \int dx dp \left( \sum_{n=0}^{\infty} \langle \hat{A}^* \phi_{xp}, \phi_{n;xp} \rangle \langle \phi_{n;xp}, \hat{\rho} \phi_{xp} \rangle \right)
\]

We now use Lebesgue’s dominated convergence theorem \[\] to show that we may reverse the order of sum and integral. In fact, it follows from the Schwartz inequality that

\[
\left| \sum_{n=0}^{m} \langle \hat{A}^* \phi_{xp}, \phi_{n;xp} \rangle \langle \phi_{n;xp}, \hat{\rho} \phi_{xp} \rangle \right|
\]

\[
\leq \left( \sum_{n=0}^{m} |\langle \hat{A}^* \phi_{xp}, \phi_{n;xp} \rangle|^2 \right)^{1/2} \left( \sum_{n=0}^{m} |\langle \phi_{n;xp}, \hat{\rho} \phi_{xp} \rangle|^2 \right)^{1/2}
\]

\[
\leq \| \hat{A}^* \phi_{xp} \| \| \hat{\rho} \phi_{xp} \|
\]
We have
\[ \|\hat{\rho}\phi_{xp}\| = \left(\langle \phi_{xp}, \hat{\rho}^2\phi_{xp}\rangle\right)^{\frac{1}{2}} \leq \left(\langle \phi_{xp}, \hat{\rho}\phi_{xp}\rangle\right)^{\frac{1}{2}} = \sqrt{2\pi Q(x, p)} \]
which, together with Inequality (21), implies
\[ \|\hat{A}^\dagger\phi_{xp}\| \|\hat{\rho}\phi_{xp}\| \leq \sqrt{2\pi K_+ (1 + x^2 + p^2)} N^+ \sqrt{Q(x, p)} \]
By assumption, \( Q(x, p) \in \mathcal{J}(\mathbb{R}^2) \). It follows that \( \|\hat{A}^\dagger\phi_{xp}\| \|\hat{\rho}\phi_{xp}\| \) is integrable. We may therefore use Lebesgue’s dominated convergence theorem \([31]\) to deduce
\[ \text{Tr}(\hat{A}\hat{\rho}) = \frac{1}{2\pi} \sum_{n=0}^\infty \int dxdp \langle \hat{A}^\dagger\phi_{xp}, \phi_{n;xp}\rangle \langle \phi_{n;xp}, \hat{\rho}\phi_{xp}\rangle \] (24)
where the sum is absolutely convergent, since
\[ \sum_{n=0}^\infty \int dxdp \|\hat{A}^\dagger\phi_{xp}, \phi_{n;xp}\rangle \langle \phi_{n;xp}, \hat{\rho}\phi_{xp}\rangle \| \leq \int dxdp \|\hat{A}^\dagger\phi_{xp}\| \|\hat{\rho}\phi_{xp}\| < \infty \]
We know from Lemma 3 that \( \hat{A} \) satisfies the conditions of Theorem 1. We may therefore use the results proved in the last section to rewrite Eq. (24) in the form
\[ \text{Tr}(\hat{A}\hat{\rho}) = \sum_{n=0}^\infty \frac{1}{n!} \int dxdp \partial^n_A \hat{H}(x, p) \partial^n Q(x, p) \]
Finally, it follows from Inequality (22), together with the fact that \( Q \in \mathcal{J}(\mathbb{R}^2) \), that we may partially integrate term-by-term to obtain
\[ \text{Tr}(\hat{A}\hat{\rho}) = \sum_{n=0}^\infty \frac{(-1)^n}{n!} \int dxdp (\partial^n_A \partial^n A\hat{n}(x, p)) Q(x, p) \]

The right hand side of Eq. (6) (expressing \( \langle \hat{A} \rangle \) in terms of the Wigner function) is defined whenever \( W \in \mathcal{J}(\mathbb{R}^2) \) and \( A_W \) exists as a tempered distribution. On the other hand, although it is true that \( Q \in \mathcal{J}(\mathbb{R}^2) \) whenever \( W \in \mathcal{J}(\mathbb{R}^2) \) (see Theorem IX.3 of ref. [31]), the fact that \( A_W \) exists as a tempered distribution is not evidently sufficient to ensure that \( \hat{A} \) is polynomial bounded. So we have not shown that Eq. (23) has the same range of validity as Eq. (6). However, it can be shown that \( \hat{A} \) is polynomially bounded if \( \phi_{xp} \in \mathcal{D}_A \cap \mathcal{D}_{\hat{A}^\dagger} \); and if \( (\hat{A}^\dagger\hat{A})_W \) and \( (\hat{A}\hat{A}^\dagger)_W \) exist as tempered distributions (see Theorem IX.4 of ref. [31]). In the applications one meets with operators satisfying these conditions much more commonly than one meets with operators for which \( A_W \) exists as a tempered distribution. For instance, every bounded operator is polynomially bounded, whereas there are many bounded operators of physical interest for which \( A_W \) fails to exist as a tempered distribution. The above result consequently represents a significant improvement on the results that were previously known.

Of course, just from the fact that Eq. (23) is convergent, it does not necessarily follow that the convergence is sufficiently rapid to make the formula useful in practical, numerical work. This question requires further investigation.

4. Conclusion

As has been stressed by Mizrahi [19], Lalović et al [1], Davidović and Lalović [33] and others, the Husimi formalism provides an especially perspicuous method for studying the relationship between quantum and classical mechanics. It establishes a one-to-one correspondence between the basic equations of the two theories, so that one can start with a classical formula, and then turn it into the corresponding quantum formula by adding successive correction terms. Moreover, the fact that
$Q(x, p)$ describes the outcome of a retrodictively optimal joint measurement of $x$ and $p$ \cite{19, 20}, means that one could reasonably argue that the Husimi function is the most natural choice for a quantum mechanical analogue of the classical probability distribution.

In this paper we have investigated the convergence properties of two of the key formulae in the Husimi formalism. We have shown that the formula giving the Husimi transform of an operator product has much better convergence properties than the corresponding formula in the Wigner function formalism. In particular, the Husimi formalism leads to a convergent generalization of the Liouville equation for a very large class of Hamiltonians. We have also shown that the convergence properties of the formula expressing the expectation value $\langle \hat{A} \rangle$ in terms of the Husimi function, although seemingly not as good as those of the corresponding formula in the Wigner function formalism, are significantly better than the often highly singular character of $A_H$ would suggest.

These results lend additional support to the suggestion that, in so far as the aim is specifically to formulate quantum mechanics as a kind of generalized version of classical mechanics, then the formalism based on the Husimi function has some significant advantages.

**Appendix A. Proof of Theorem**

For arbitrary complex $x$, $p$ define

$$F(x, p) = \frac{\langle \phi_{x-p}, \hat{A} \phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle}$$

where $x_{\pm}$, $p_{\pm}$ are the (real) variables defined by Eqs. \cite{13} and \cite{14}.

It is easily seen that, if $x$, $p$ are both real, then

$$F(x, p) = \langle \phi_{xp}, \hat{A} \phi_{xp} \rangle = A_H(x, p)$$

The problem thus reduces to that of showing that, if $\hat{A}$ has the properties stipulated, then $F$ is holomorphic. We will do this by showing that $F$ satisfies the Cauchy-Riemann equations with respect to the complex variables

$$z_{\pm} = \frac{1}{\sqrt{2}} (x_{\pm} \pm ip_{\pm}) = \frac{1}{\sqrt{2}} (x \pm ip)$$

(25)

In fact, it is straightforward to show that $\phi_{xp}$, regarded as a vector-valued function of two real variables, is differentiable in the norm topology; the derivatives being given by

$$\frac{\partial}{\partial x} \phi_{xp} = \frac{1}{\sqrt{2}} \phi_{1, xp} - \frac{i}{2} p \phi_{xp}$$

$$\frac{\partial}{\partial p} \phi_{xp} = \frac{i}{\sqrt{2}} \phi_{1, xp} + \frac{i}{2} x \phi_{xp}$$

Also,

$$\langle \phi_{x-p}, \phi_{x+p} \rangle = \exp \left[ -\frac{1}{4} (x_+ - x_-)^2 - \frac{1}{4} (p_+ - p_-)^2 + \frac{i}{2} (p_+ x_- - p_- x_+) \right]$$

Consequently, $F$ is differentiable with respect to the variables $x_-, p_-$. Moreover

$$\frac{\partial}{\partial x_-} F(x, p) = \frac{1}{\sqrt{2}} \frac{\langle \phi_{1, x-p}, \hat{A} \phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} + \frac{1}{\sqrt{2}} (z_- - z_+) F(x, p)$$

$$= i \frac{\partial}{\partial p_-} F(x, p)$$

(26)

from which it follows that $F$ satisfies the Cauchy-Riemann equations with respect to the complex variable $z_- = (x_- - ip_-)/\sqrt{2}$. 

We can alternatively write

\[ F(x, p) = \frac{\langle \hat{A}^1 \phi_{x-p}, \phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} \]

Consequently, \( F \) is also differentiable with respect to the real variables \( x_+, p_+ \). Moreover

\[ \frac{\partial}{\partial x_+} F(x, p) = \frac{1}{\sqrt{2}} \frac{\langle \hat{A}^1 \phi_{x-p}, \phi_{1;x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} + \frac{1}{\sqrt{2}} (z_+^* - z_-) F(x, p) \]

\[ = -i \frac{\partial}{\partial p_+} F(x, p) \tag{27} \]

from which it follows that \( F \) satisfies the Cauchy-Riemann equations with respect to the complex variable \( z_+ = (x_+ + ip_+)/\sqrt{2} \).

If \( \hat{A} \) has the properties specified in the statement of theorem, then we see from Eqs. (24) and (27) that the partial derivatives \( \partial F/\partial x_\pm, \partial F/\partial p_\pm \), are continuous functions on \( \mathbb{R}^2 \). It follows \( \text{(23)} \) that \( F \) is a holomorphic function of the complex variables \( z_\pm \). Referring to Eq. (25) it can be seen that the variables \( z_\pm \) are linear combinations of \( x, p \). We conclude that \( F \) is a holomorphic function of \( x, p \).

**APPENDIX B. PROOF OF LEMA 2**

It is straightforward to show that \( \phi_{n;x,-} \), regarded as a vector valued function of two real variables, is differentiable in the norm topology. Moreover

\[ \frac{1}{\sqrt{2}} \left( \frac{\partial}{\partial x_-} - i \frac{\partial}{\partial p_-} \right) \phi_{n;x,-} = \sqrt{n + 1} \phi_{n+1;x,-} + \frac{1}{2} z_- \phi_{n;x,-} \]

Hence

\[ \frac{1}{\sqrt{2}} \left( \frac{\partial}{\partial x_-} + i \frac{\partial}{\partial p_-} \right) \frac{\langle \phi_{n;x,-}, \hat{A}\phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} \]

\[ = \sqrt{n + 1} \frac{\langle \phi_{n+1;x,-}, \hat{A}\phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} + (z_+^* - z_-) \frac{\langle \phi_{n;x,-}, \hat{A}\phi_{x+p} \rangle}{\langle \phi_{x-p}, \phi_{x+p} \rangle} \]

Iterating this result, and using

\[ \frac{1}{2^{r/2}} \left( \frac{\partial}{\partial x_-} + i \frac{\partial}{\partial p_-} \right)^r A_H(x, p) = \frac{\partial^r}{\partial z_-^r} A_H(x, p) \]

we obtain Eq. (15).

The proof of Eq. \( \text{(10)} \) is similar.

**APPENDIX C. PROOF OF LEMA 3**

**Proof of (1).** We need to show that, if \( \hat{A} \) is polynomial bounded, then the functions \( \langle \phi_{x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle, \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) and \( \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) are continuous.

Consider the function \( \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \). We have

\[ \left| \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle - \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \right| \]

\[ \leq \left| \langle \phi_{1;x_1p_1} - \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \right| + \left| \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \right| \]

In view of Eq. (24) we have

\[ \left| \langle \phi_{1;x_1p_1} - \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \right| \leq K(1 + x_2^2 + p_2^2)^N \| \phi_{1;x_1p_1} - \phi_{1;x_1p_1} \| \]
Also, using the completeness relation for coherent states, together with Eq. (21), we find

\[ \left| \langle \phi_{1;x_1p_1}, \hat{A}(\phi_{x_1^2p_2} - \phi_{x_2p_2}) \rangle \right| \]

\[ = \frac{1}{2\pi} \int dx_3 dp_3 \left| \langle \phi_{1;x_1p_1}, \phi_{x_3p_3} \rangle \langle \hat{A} \phi_{x_3p_3}, (\phi_{x_1^2p_2} - \phi_{x_2p_2}) \rangle \right| \]

\[ \leq f(x_1, p_1) \| \phi_{x_1^2p_2} - \phi_{x_2p_2} \| \]

where \( f \) is the polynomial

\[ f(x_1, p_1) = \frac{K_+}{2\pi} \int dx_3 dp_3 \left| \langle \phi_{1;x_1p_1}, \phi_{x_3p_3} \rangle (1 + x_3^2 + p_3^2)^{N^+} \right| \]

\[ = \frac{K_+}{2\pi} \int dx_3 dp_3 \sqrt{1 + x_3^2 + p_3^2} (1 + (x_3^2 + x_1^2 + (p_3 + p_1)^2)^{N^+} \]

\[ \times \exp \left[ -\frac{1}{4} (x_3^2 + p_3^2) \right] \]

Putting these results together we find

\[ \left| \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_3p_3} \rangle - \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \right| \]

\[ \leq K_- (1 + x_2^2 + p_2^2)^{N^+} \| \phi_{1;x_1p_1} \| + f(x_1, p_1) \| \phi_{x_1^2p_2} - \phi_{x_2p_2} \| \]

\( \phi_{xp} \) and \( \phi_{1xp} \), regarded as vector-valued functions on \( \mathbb{R}^2 \), are continuous in the norm topology. Consequently

\[ \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_3p_3} \rangle \rightarrow \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \]

as \( (x_1, p_1, x_2, p_2) \rightarrow (x_1, p_1, x_2, p_2) \). It follows that \( \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) is continuous. Continuity of the functions \( \langle \phi_{x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) and \( \langle \phi_{1;x_1p_1}, \hat{A}\phi_{x_2p_2} \rangle \) is proved in the same way.

**Proof of (2).** The completeness relation for coherent states implies

\[ A_H(x, p) = \langle \phi_{xp}, \hat{A}\phi_{xp} \rangle = \frac{1}{2\pi} \int dx' dp' \langle \phi_{xp}, \phi_{x'p'} \rangle \langle \hat{A} \phi_{x'p'}, \phi_{xp} \rangle \]

Using

\[ \partial_+ \phi_{n;xp} = \sqrt{n + 1} \phi_{(n+1);xp} + \frac{1}{2} z^* \phi_{n;xp} \]

\[ \partial_- \phi_{n;xp} = \begin{cases} -\frac{1}{2} z \phi_{xp} & \text{if } n = 0 \\ -\sqrt{n} \phi_{(n-1);xp} - \frac{1}{2} z \phi_{n;xp} & \text{if } n > 0 \end{cases} \]

[where \( \partial_\pm = 2^{-1/2} (\partial_x \mp i \partial_p) \) and \( z = 2^{-1/2} (x + ip) \)], and differentiating under the integral sign, it is not difficult to show that

\[ \partial_x^m \partial_p^n A_H(x, p) = \sum_{r,s=0}^{n+m} c_{rs} \int dx' dp' \langle \phi_{r;xp}, \phi_{s;xp} \rangle \langle \hat{A} \phi_{x'p'}, \phi_{s;xp} \rangle \]

for suitable constants \( c_{rs} \). We have

\[ \left| \langle \phi_{r;xp}, \phi_{x'p'} \rangle \right| \]

\[ = \frac{1}{2\pi \sqrt{r!}} ((x' - x)^2 + (p' - p)^2)^{\frac{r}{2}} \exp \left[ -\frac{1}{4} (x' - x)^2 - \frac{1}{4} (p' - p)^2 \right] \]

In view of Inequality (21) it follows that

\[ \left| \int dx' dp' \langle \phi_{r;xp}, \phi_{x'p'} \rangle \langle \hat{A} \phi_{x'p'}, \phi_{s;xp} \rangle \right| \]
\[
\leq \frac{K_+}{2\pi\sqrt{r!}} \int dx'' dp'' \left( 1 + (x'' + x)^2 + (p'' + p)^2 \right)^{N_+} \\
\times (x''^2 + p''^2)^{\frac{1}{2}} \exp \left[ -\frac{1}{4}(x''^2 + p''^2) \right]
\]

It can be seen that the expression on the right hand side of this inequality is a polynomial in \(x\) and \(p\). Consequently

\[
\left| \partial_x^n \partial_p^m A_H(x, p) \right| \leq f(x, p)
\]

for some polynomial \(f(x, p)\). The claim is now immediate.
