Electronic structure of fluorides: general trends for ground and excited state properties

Emiliano Cadelano and Giancarlo Cappellini
Department of Physics, University of Cagliari and Istituto Officina dei Materiali (IOM) del Consiglio Nazionale delle Ricerche (CNR), Unita’ Operativa SLACS, S.P. Monserrato-Sestu Km 0.700, I-09042 Monserrato (Cagliari), Italy
(Dated: August 1, 2011)

The electronic structure of fluorite crystals are studied by means of density functional theory within the local density approximation for the exchange correlation energy. The ground-state electronic properties, which have been calculated for the cubic structures CaF$_2$, SrF$_2$, BaF$_2$, CdF$_2$, HgF$_2$, PbF$_2$, using a plane waves expansion of the wave functions, show good comparison with existing experimental data and previous theoretical results. The electronic density of states at the gap region for all the compounds their energy-band structure have been calculated and compared with the existing data in the literature. General trends for the ground-state parameters, the electronic energy-bands and transition energies for all the fluorides considered are given and discussed in details. Moreover, for the first time results for HgF$_2$ have been presented.

1. INTRODUCTION

Fluorides and fluorite-type crystals have attracted much interest for their intrinsic optical properties and their potential applications in optoelectronic devices. The technological importance of CaF$_2$ is due mainly to its optical properties; indeed CaF$_2$ has a direct band gap at $\Gamma$ of 12.1 eV and an indirect band gap estimated around 11.8 eV. Calcium fluorite CaF$_2$ as well as all the other fluorides, is a highly ionic insulator with a large band gap, and its lattice structure is a cubic Fm$\overline{3}$m within three ions per unit cell, i.e. one cation placed in the origin and two anions $F^-$ are situated at $\pm(\frac{a}{2}, \frac{a}{2}, \frac{a}{2})$. Here we shall consider CaF$_2$, SrF$_2$, BaF$_2$ (with cations belonging to the II group) and CdF$_2$, HgF$_2$ (with cation belonging to group IIB) and, finally, PbF$_2$ (with cation belonging to IV group). We refer to them respectively in the present text as II-compounds, IIB-compounds and PbF$_2$. We therefore propose the first systematic study of the electronic properties of some fluorides compounds within the same computational approach. Until now the theoretical studies of these compounds have been tackled in separate forms and with different techniques. Therefore no general and systematic trend for the family of these compounds could be obtained. The DFT-LDA studies are of particular importance and are benchmarks for subsequent researches to perform excited states and optical properties calculations. The latter rely on more sophisticated techniques which must start from well converged DFT-LDA calculations (e.g. perturbative $G_0W_0$, self-consistent GW, BSE etc.). In the following lines we proceed to consider the experimental data and the theoretical results for fluorides present in the literature.

a. Experimental Scenario Due to its importance in application and basic research, experiments on CaF$_2$ and fluorides compounds have been carried out for a long time. The optical constant of CaF$_2$ in the extreme ultraviolet has been studied by discharge-tube technique. Reflectance spectra, transition energies for CaF$_2$, BaF$_2$, SrF$_2$ and other ionic compounds have been measured by synchrotron radiation facility later on. Studies on PbF$_2$, CaF$_2$, SrF$_2$ and BaF$_2$ dielectric properties have been published as a function of pressure and temperature by capacitance and dielectric loss measurements. Satellites in the X-ray spectra for CaF$_2$, SrF$_2$, BaF$_2$, density of states for intraband transitions, have been studied by photoelectron spectrometry. The effects of Eu defects in PbF$_2$ (PbF$_2$: Eu$^{3+}$) relative to fluorescence/electronic excitation spectra and dielectric relaxation have been analyzed by laser absorption spectra techniques. PbF$_2$ and CdF$_2$ mixed crystals absorption coefficients have been reported by spectrophotometry measurements. Neutron diffraction techniques have been employed to determine the PbF$_2$ pressure and temperature phase diagram. The study by different techniques of the phase diagram of HgF$_2$ and other Hg compounds should also be mentioned here (even if for HgF$_2$ no results appear in this work due to hydra-
tion of the sample). Recently schematic experimental phase diagrams for HgF$_2$ and HgF have been also reported.  

b. Theoretical Scenario Various theoretical methods have been applied to study either the ground state or the excited states of the fluorides compounds. One of the first works of relevance is the one in which elastic constants, pressure derivatives of 2$^{nd}$ order elastic constants, static dielectric constant and its strain dependence for CaF$_2$, SrF$_2$, BaF$_2$, have been calculated within a shell model.  
The energy bands and reflectance spectra of CaF$_2$ and CdF$_2$ have been determined afterwards within a combined tight-binding and pseudopotential method.  
Mixed crystals of CaF$_2$, SrF$_2$, CdF$_2$, β-PbF$_2$ have been studied with respect to their energy bands and DOS within LMTO method.  
A phenomenological method has been then applied to calculate specific heat of β-PbF$_2$, CaF$_2$ and other compounds.  
Linear and non-linear optical properties of the cubic insulators CaF$_2$, SrF$_2$, CdF$_2$, BaF$_2$ and other compounds have been determined by first principles OLCAO.  
Points defects study in CdF$_2$ have been performed within the plane wave pseudopotential method.  
With respect to electronic excitation properties and energy bandgaps, electronic band structure of CaF$_2$ and other compounds have been determined by DFT-GW, using plane wave basis set and ionic pseudopotentials (PW-PP) scheme.  
Using the hybrid B3PW functional, the electronic structures of defected fluorides, namely CaF$_2$ and BaF$_2$, have been calculated.  
The $e_{2g}(\alpha)$ function after an iterative procedure using an effective Hamiltonian has been calculated for CaF$_2$ and GaN, within PW-PP considering a screened interaction for $e-h$ coupling.  
Native and rare-earth doped defects complexes in PbF$_2$ have been studied by atomistic simulation.  

In this paper, we are interested in either the structural and the electronic properties of each fluoride, and in comparison/trend studies for the whole crystallographic family. We have computed therefore the electronic and structural properties of different fluorides, CaF$_2$, SrF$_2$, BaF$_2$ (with cation belonging to group II), CdF$_2$, HgF$_2$ (with cation belonging to group IIB), β-PbF$_2$, within the same first-principles pseudopotential plane-wave method.

| $a_0$ [Å] | present | LDA | Theory | Exp. |
|-----------|---------|-----|--------|------|
| CaF$_2$   | 5.30    | 5.34 | 5.46   | 5.46 |
| SrF$_2$   | 5.68    | -    | 5.79   | 5.78 |
| BaF$_2$   | 6.09    | -    | 6.26   | 6.17 |
| CdF$_2$   | 5.31    | 5.36 | 5.39   | 5.46 |
| HgF$_2$   | 5.47    | -    | 5.55   | 5.54 |
| β-PbF$_2$ | 5.77    | -    | 5.94   | 5.94 |

### Table II: Bulk moduli of fluorides. Data in column "Theory" are previous theoretical results. Data in column "Exp." are after different experimental references.

| B$_0$ [GPa] | present | Theory | Exp. |
|-------------|---------|--------|------|
| CaF$_2$     | 103.01  | 91     | 90   |
| SrF$_2$     | 83.75   | -      | -    |
| BaF$_2$     | 69.39   | 50.44  | 59   |
| CdF$_2$     | 123.96  | 123    | -    |
| HgF$_2$     | 117.03  | -      | -    |
| β-PbF$_2$   | 93.22   | 60    | 64   |

### II. COMPUTATIONAL DETAILS

All the calculations for the fluorides under study have been performed using density functional theory (DFT)
method implemented in the plane-wave basis code VASP.  
Projectors augmented wave pseudopotentials (PAW) have been used in the localized density approximation (LDA) for the exchange correlation energy treated within the scheme of Ceperley and Alder parametrized by Perdew and Zunger.

Relativistic effects have been included in the calculations and spin-orbit coupling has been considered for the valence electrons.

The conventional cell of the crystals is shown in Fig. 1a, in which the ions $F^{(-)}$ (drawn as little spheres) form a cubic sublattice surrounded by a cubic face-centered lattice of cations (in the picture shown as large spheres labeled e.g. as Calcium). Fluorides with cations belonging to the II and IIB groups show a stable phase in this crystallographic structure. On the other hand, at low pressure the PbF$_2$ shows two structural phases, namely orthorhombic ($\alpha$) and cubic ($\beta$). Although the cubic phase $\beta$-PbF$_2$ is the most stable in ambient conditions, while the orthorhombic $\alpha$-PbF$_2$ becomes stable at high pressure.

In Fig. 1b, the Brillouin zone has been drawn for the $Fm\overline{3}m$ space group; the paths in the $k$-space chosen in our calculations for the electronic band structures have also been shown. All calculations are performed with the total energy convergence within $1.5 \times 10^{-5}$eV with kinetic energy cut-off depending on the cation of the compound under study (at least of 550eV). A Monkhorst-Pack $k$-point mesh of $4 \times 4 \times 4$ has been chosen to relax the cell parameters, till the largest value for the interatomic forces result smaller than $1.5 \times 10^{-5}$ eV/Å. Lattice constants for each fluoride ($a_0$, in Tab. I), as well as the bulk moduli ($B_0$ in Tab. II) have been calculated with the Murnaghan equation of state.

### III. RESULTS AND DISCUSSION

Trends for lattice constants and bulk moduli are showed in Fig. 2 with the corresponding experimental data from literature, if available. From Table I and Fig. 2 an overall good comparison appears between experimental data and present results relative to lattice constants with maximum deviation of 3%. Compounds with cations belonging to the II and IIB
Table III: For the fluorides considered here, bandwidths and energy gaps as found in our DFT-LDA study. Direct and indirect DFT-LDA band gap energies. In the first column, current results are shown. Data are in eV.

| Solid   | Minimum Direct Band gap | Minimum Indirect Band gap | Valence Bandwidth |
|---------|-------------------------|---------------------------|-------------------|
|         | present LDA GW Exp.     | present LDA GW Exp.       | Valence Bandwidth |
| CaF₂    | \( \Gamma \rightarrow \Gamma \) 7.71 7.11 11.80 12.10 | \( \Gamma \rightarrow \Gamma \) 7.43 6.85 11.50 11.80 | 3.17 2.82 3.26 3.29 |
| SrF₂    | \( \Gamma \rightarrow \Gamma \) 6.99 11.25 11.00 | \( \Gamma \rightarrow \Gamma \) 6.89 6.77 10.60 10.00 | 2.33 2.80 2.50 |
| BaF₂    | \( \Gamma \rightarrow \Gamma \) 6.67 11.00 11.00 11.50 | \( \Gamma \rightarrow \Gamma \) 6.58 7.19 10.00 10.00 | 1.78 2.50 |
| CdF₂    | \( \Gamma \rightarrow \Gamma \) 3.37 3.30 3.09 | \( \Gamma \rightarrow \Gamma \) 2.94 2.80 7.80 7.50 | 5.79 |
| HgF₂    | \( \Gamma \rightarrow \Gamma \) 0.35 | \( \Gamma \rightarrow \Gamma \) 4.16 | 6.38 |
| β-PbF₂  | \( X \rightarrow X \) 4.09 | \( W \rightarrow X \) 3.41 | 7.16 6.33 |

Groups show a linear behavior with respect to Mendeleev table period of corresponding cation. Moreover, as shown in Table II and Fig. 2, bulk moduli show a less satisfactory agreement with experimental results (maximum deviation within 20% in the case of II group, within 45% for the β-PbF₂). Also for bulk moduli of compounds with cations belonging to the II and IIB groups, an almost linear behavior results with respect to the Mendeleev’s period. For IIB group no available experimental data supports the theoretical trend.

Energy band structure, total and projected density of states (DOS) are shown in the region of the gap in Figs. 4, 5. Direct and indirect minimum band gaps are also clearly shown. In Table III these data are shown in comparison to previous results and experimental data; valence bandwidths are also reported in comparison with theoretical and experimental results. In Table IV the main vertical transitions are reported for all the compounds. In the following lines, in order to extract general trends for the electronic excitation properties in the stable cubic fluorides under study, we shall compare the results for the different fluorides considering first compounds with cations belonging to the II group, namely Ca, Sr and Ba, then compounds with metal belonging to IIB group, namely Cd and Hg. Finally for β-PbF₂ data will be analysed separately. All these compounds show a minimum direct band gap at the \( \Gamma \) point, except β-PbF₂. Concerning the smallest gap, the fundamental one, all the compounds herein treated are indirect gap insulators apart from HgF₂ which shows a direct fundamental band gap (Table III). Note that absolute values for the gaps show the so-called band-gap underestimate which can be resolved going beyond DFT-LDA, by using more accurate techniques for the excited states (e.g. GW ones, see Table III). This issue will not be addressed in the present work and will be the subject of future research. Moreover trends on electronic excitation energies as shown in the following should not be affected by the above problem.

For II-compounds, a decrease of the direct gap at \( \Gamma \) of 1.04 eV is similar to the 1.10 eV decrease after the experimental data (see also Fig. 4). On the other hand, a decrease of 0.54 eV for the \( X-\Gamma \) transitions for calcium and strontium fluorides results which can be compared with a 1.20 eV decrease from the experiments. Considering barium fluoride, the \( X-\Gamma \) transition is not the minimum, but that which occurs at \((1/4,1/4,0) - \Gamma\) (see also Fig. 4c). However, considering the value for the \( X-\Gamma \) transition shown in Tab. IV, we confirm a smaller value of 0.31 eV with respect to the same transition for SrF₂ (to compare with 0.6 eV experimental decrease). Considering the valence bandwidth, a 1.39 eV decrease going from Ca to Ba occurs, and that decrease can be compared to a 0.70 eV experiment.
Table IV: Energy band gaps (eV) after present work.

| Direct gap | CaF$_2$ | SrF$_2$ | BaF$_2$ | CdF$_2$ | HgF$_2$ | β-PbF$_2$ |
|------------|---------|---------|---------|---------|---------|-----------|
| $L \to L$  | 9.35    | 10.59   | 9.29    | 7.62    | 4.31    | 4.62      |
| $\Gamma \to \Gamma'$ | 7.71    | 6.99    | 6.67    | 3.37    | 0.35    | 7.45      |

IV. CONCLUSIONS

The DFT-LDA electronic structures for ground-state and excited states for some cubic fluorides have been studied in detail. The electronic density of states (DOS) at the gap region for all the compounds and their energy-band structure have been calculated and compared with existing experiments and previous theoretical results. The electronic energy-bands and transition energies are given and discussed. Within the same DFT-LDA scheme, general trends for the ground-state parameters and the DOS are also given. The above trends show good comparison with experimental data and theoretical results. Relatively to electronic excitations, the conduction bands for II-compounds are mostly dominated by the cations d-orbitals, while for the IIB-compounds the tail of the DOS at the lowest conduction bands shows a largely s-type character. The obtained DFT-LDA valence bandwidths agree with experimental values within 30%. The present systematic DFT-LDA study is of particular interest for future researches on excited states and optical properties calculations of fluorides. We plan to carry out such calculations in next future by using...
Figure 5: Energy band structures, total and projected density of states (DOS) are shown in the region of the band gap for the IIB-compounds and $\beta$-PbF$_2$.
