LIMITING OPERATIONS FOR SEQUENCES OF QUANTUM RANDOM VARIABLES AND A CONVERGENCE THEOREM FOR QUANTUM MARTINGALES

KYLER S. JOHNSON AND MICHAEL J. KOZDRON

Abstract. We study quantum random variables and generalize several classical limit results to the quantum setting. We prove a quantum analogue of Lebesgue’s dominated convergence theorem and use it to prove a quantum martingale convergence theorem. This quantum martingale convergence theorem is of particular interest since it exhibits non-classical behaviour; even though the limit of the martingale exists and is unique, it is not explicitly identifiable. However, we provide a partial classification of the limit through a study of the space of all quantum random variables having quantum expectation zero.

1. Introduction

In 2011, while studying classical and non-classical convexity properties of the space of positive operator valued measures on the Borel sets of a locally compact Hausdorff space $X$ with values in $B(H)$, the algebra of linear operators acting on a $d$-dimensional Hilbert space $H$, Farenick, Plosker, and Smith [4] introduced a transform that associates any positive operator valued measure $\nu$ with a certain completely positive linear map $\Gamma(\nu)$ of the homogeneous C*-algebra $C(X) \otimes B(H)$ into $B(H)$. This association was achieved by using an operator valued integral in which operator valued functions are integrated with respect to positive operator valued measures and which has the feature that the integral of a random quantum effect is itself a quantum effect.

Farenick and Kozdron [2] helped provide a better mathematical understanding of quantum probability by introducing a quantum analogue for the expected value $E_{\nu}[\psi]$ of a quantum random variable $\psi$ relative to a quantum probability measure $\nu$ using the operator valued integral of [4]. This led to theorems for a change of quantum measure and a change of quantum variables. They also introduced a quantum conditional expectation which resulted in quantum versions of some standard identities for Radon-Nikodým derivatives, and allowed them to formulate and prove a quantum analogue of Bayes’ rule.

It is a basic fact of functional analysis that if $\psi : X \to \mathbb{C}$ is an essentially bounded function on a probability space $(X, \mathcal{F}(X), \mu)$, then the essential range of $\psi$ is precisely the spectrum of $\psi$, where one considers $\psi$ as an element of the von Neumann algebra $L^{\infty}(X, \mu)$. Recently, Farenick, Kozdron, and Plosker [3] arrived at a similar result for essentially bounded quantum random variables on quantum probability spaces using higher dimensional spectra. Their investigation of quantum variance also involved notions from spectral theory, and they discovered that the quantum moment problem admits a characterisation entirely within spectral terms.

In the present work, we build on these earlier results by considering for the first time limiting operations for sequences of quantum random variables and quantum probability measures including a quantum analogue of Lebesgue’s dominated convergence theorem and a discrete Fubini-type theorem. As in those earlier investigations, the noncommutativity of operator algebra leads to some structure that simply does not appear in the classical setting. Using the quantum conditional

Key words and phrases. positive operator valued measure; quantum probability space; quantum martingale convergence theorem; noncommutative probability.
We will always write \( \mathcal{H} \) for a \( d \)-dimensional Hilbert space, \( \mathcal{B}(\mathcal{H}) \) for the C*-algebra of linear operators acting on \( \mathcal{H} \), and \( \mathcal{B}(\mathcal{H})_+ \) for the cone of positive operators. The predual of \( \mathcal{B}(\mathcal{H}) \) is denoted by \( \mathcal{T}(\mathcal{H}) \), the space of trace-class operators. Since \( \mathcal{H} \) is finite dimensional, \( \mathcal{B}(\mathcal{H}) \) and \( \mathcal{T}(\mathcal{H}) \) coincide as sets. Finally, \( X \) shall denote a locally compact Hausdorff space and \( \mathcal{F}(X) \) a \( \sigma \)-algebra of subsets of \( X \). A particular \( \sigma \)-algebra of interest is \( \mathcal{O}(X) \), the Borel sets of \( X \). A density operator, or state, on \( \mathcal{H} \) is a positive trace-class operator \( \rho \) such that \( \text{Tr}(\rho) = 1 \); the set of all density operators is denoted by \( \mathcal{S}(\mathcal{H}) \). By a quantum effect we mean a positive operator \( h \in \mathcal{B}(\mathcal{H})_+ \) with the property that every eigenvalue \( \lambda \) of \( h \) satisfies \( 0 \leq \lambda \leq 1 \), and we let \( \mathcal{Eфф}(\mathcal{H}) \) denote the set of quantum effects. Note that each state \( \rho \in \mathcal{S}(\mathcal{H}) \) is also a quantum effect. A set function \( \nu : \mathcal{F}(X) \rightarrow \mathcal{B}(\mathcal{H}) \) is called a positive operator valued measure (POVM) if

- \( \nu(E) \in \mathcal{Eфф}(\mathcal{H}) \) for every \( E \in \mathcal{F}(X) \),
- \( \nu(X) \neq 0 \), and
- for every countable collection \( \{E_k\}_{k=1}^{\infty} \subseteq \mathcal{F}(X) \) with \( E_j \cap E_k = \emptyset \) for \( j \neq k \) we have

\[
\nu\left(\bigcup_{k=1}^{\infty} E_k\right) = \sum_{k=1}^{\infty} \nu(E_k).
\]

If, in addition, \( \nu(X) = 1 \in \mathcal{B}(\mathcal{H}) \), then \( \nu \) is called a quantum probability measure. The convergence in (1) above is normally assumed to be with respect to the ultraweak topology; however, because \( \mathcal{B}(\mathcal{H}) \) has finite dimension, the convergence in (1) may be taken with respect to any of the usual operator topologies on \( \mathcal{B}(\mathcal{H}) \). The POVM \( \nu : \mathcal{F}(X) \rightarrow \mathcal{B}(\mathcal{H}) \) induces the classical (i.e., scalar valued) measure \( \mu \) via \( \mu = \frac{1}{d} \text{Tr} \circ \nu \), where \( \text{Tr} \) is the canonical trace on \( \mathcal{B}(\mathcal{H}) \). Note that if \( \nu \) is a quantum probability measure, then \( \mu \) is a classical probability measure. We call the triple \( (X, \mathcal{F}(X), \nu) \) a quantum probability space.

A function \( \psi : X \rightarrow \mathcal{B}(\mathcal{H}) \) is said to be measurable (i.e., a quantum random variable) if, for every pair \( \xi, \eta \in \mathcal{H} \), the complex valued function \( x \mapsto \langle \psi(x)\xi, \eta \rangle \) is measurable (i.e., a random variable) in the classical sense. In fact, it is known [3] that \( \psi : X \rightarrow \mathcal{B}(\mathcal{H}) \) is measurable if and only if \( \psi^{-1}(U) \) is a measurable set, for every open set \( U \subseteq \mathcal{B}(\mathcal{H}) \).

The predual of the von Neumann algebra \( L^{\infty}(X, \mu) \bar{\otimes} \mathcal{B}(\mathcal{H}) \) is given by \( L^1_{\mathcal{T}(\mathcal{H})}(X, \mu) \); see Theorem IV.7.17 of [9]. In particular, if \( \Psi \in L^{\infty}(X, \mu) \bar{\otimes} \mathcal{B}(\mathcal{H}) \), then there is a bounded quantum random variable \( \psi : X \rightarrow \mathcal{B}(\mathcal{H}) \) such that, for each \( f \in L^1_{\mathcal{T}(\mathcal{H})}(X, \mu) \), the complex number \( \Psi(f) \) is given by

\[
\Psi(f) = \frac{1}{d} \int_X \text{Tr} \left( f(x)\psi(x) \right) \, d\mu(x).
\]

Although \( \psi \) is not unique, it is unique up to a set of \( \mu \)-measure zero. We therefore identify \( \Psi \) and \( \psi \) and consider the elements of \( L^{\infty}(X, \mu) \bar{\otimes} \mathcal{B}(\mathcal{H}) \) to be bounded quantum random variables \( \psi : X \rightarrow \mathcal{B}(\mathcal{H}) \). Note that \( L^{\infty}(X, \mu) \bar{\otimes} \mathcal{B}(\mathcal{H}) \cong L^{\infty}(X, \mu) \otimes M_d(\mathbb{C}) \) where \( M_d(\mathbb{C}) \) is the space of \( d \times d \) matrices over \( \mathbb{C} \).
We end this section by stating a number of theorems and definitions from [2, 3], and [4] relevant for our purposes. Recall that if \( \nu_1 \) and \( \nu_2 \) are both positive operator valued measures on \((X, F(X))\), then \( \nu_2 \) is absolutely continuous with respect to \( \nu_1 \), written \( \nu_2 \ll_{ac} \nu_1 \), if \( \nu_2(E) = 0 \) for every \( E \in F(X) \) with \( \nu_1(E) = 0 \). Furthermore, if \( \mu \) is a classical measure, then we can always view \( \mu \) as the scalar valued POVM \( \mu \cdot 1 \).

**Theorem 2.1.** If \( \nu \) is a POVM on \((X, F(X))\), then \( \nu \) is absolutely continuous with respect to the induced classical measure \( \mu \), and there exists an \( F(X) \)-measurable function \( \frac{d\nu}{d\mu} \) such that

\[
(2) \quad \int_E \left< \frac{d\nu}{d\mu}(x)\xi, \xi \right> d\mu(x) = \langle \nu(E)\xi, \xi \rangle,
\]

for all \( E \in F(X) \) and all \( \xi \in \mathcal{H} \). The function \( \frac{d\nu}{d\mu} \) is called the principal Radon-Nikodým derivative of \( \nu \) and is a positive operator for \( \mu \)-almost all \( x \in X \).

**Definition 2.2.** A measurable function \( \psi : X \to \mathcal{B}(\mathcal{H}) \) is \( \nu \)-integrable if for every density operator \( \rho \) the complex valued function

\[
\psi_{\rho}(x) = \text{Tr} \left( \rho \left( \frac{d\nu}{d\mu}(x) \right)^{1/2} \psi(x) \left( \frac{d\nu}{d\mu}(x) \right)^{1/2} \right), \quad x \in X,
\]

is \( \mu \)-integrable. The integral of a \( \nu \)-integrable function \( \psi : X \to \mathcal{B}(\mathcal{H}) \) is defined to be the unique operator acting on \( \mathcal{H} \) having the property that

\[
\text{Tr} \left( \rho \int_X \psi \, d\nu \right) = \int_X \psi_{\rho} \, d\mu,
\]

for every density operator \( \rho \).

**Theorem 2.3.** If \( \nu_1, \nu_2 \) are POVMs on \((X, F(X))\), then \( \nu_2 \ll_{ac} \nu_1 \) if and only if there exists a bounded \( \nu_1 \)-integrable \( F(X) \)-measurable function \( \frac{d\nu_2}{d\nu_1} \), unique up to sets of \( \nu_1 \)-measure zero, such that

\[
\nu_2(E) = \int_E \frac{d\nu_2}{d\nu_1} \, d\nu_1
\]

for every \( E \in F(X) \). Moreover,

\[
\frac{d\nu_2}{d\nu_1} = \left( \frac{d\mu_2}{d\mu_1} \right) \left[ \left( \frac{d\nu_1}{d\mu_1} \right)^{-1/2} \frac{d\nu_2}{d\mu_2} \left( \frac{d\nu_1}{d\mu_1} \right)^{-1/2} \right]
\]

and is called the non-principal Radon-Nikodým derivative of \( \nu_2 \) with respect to \( \nu_1 \).

Recall from [6] and [8] that if \( a, b \in \mathcal{B}(\mathcal{H})_+ \) are both invertible, then the geometric mean of \( a \) and \( b \) is the positive operator \( a \# b \) defined by \( a \# b = a^{1/2} (a^{-1/2} b a^{-1/2})^{1/2} a^{1/2} \). If \( a, b \in \mathcal{B}(\mathcal{H})_+ \) are non-invertible, then \( a \# b \) is defined by

\[
a \# b = \lim_{\varepsilon \to 0^+} (a + \varepsilon 1) \# (b + \varepsilon 1),
\]

with convergence in the strong operator topology. If \( \nu_1 \) and \( \nu_2 \) are both quantum probability measures with \( \nu_2 \ll_{ac} \nu_1 \) and if \( \psi : X \to \mathcal{B}(\mathcal{H}) \) is a quantum random variable, then we define

\[
\psi \boxtimes \frac{d\nu_2}{d\nu_1} = \left( \frac{d\nu_1}{d\mu_1} \right)^{-1} \# \frac{d\nu_2}{d\nu_1} \left( \frac{d\nu_1}{d\mu_1} \right)^{1/2} \psi \left( \frac{d\nu_1}{d\mu_1} \right)^{1/2} \left( \frac{d\nu_1}{d\mu_1} \right)^{-1} \# \frac{d\nu_2}{d\nu_1}.
\]
In particular,
\[ \psi \boxtimes \frac{d\nu}{d\mu} = \left( \frac{d\nu}{d\mu} \right)^{1/2} \psi \left( \frac{d\nu}{d\mu} \right)^{1/2}. \]

**Definition 2.4.** If \( \nu : \mathcal{F}(X) \to \mathcal{B} \) is a quantum probability measure, then the quantum expectation of \( \psi \) with respect to \( \nu \) is the map \( \mathbb{E}_\nu : L^\infty(X,\mu) \boxtimes \mathcal{B} \to \mathcal{B} \) defined by
\[ \mathbb{E}_\nu[\psi] = \int_X \psi \, d\nu. \]

Recall [7, Chapter 3] that a linear map \( \varphi : \mathcal{A} \to \mathcal{B} \) of unital C*-algebras is a unital completely positive (ucp) map if \( \varphi(1_A) = 1_B \) and the induced linear maps \( \varphi \otimes \text{id}_a : \mathcal{A} \otimes M_n(\mathbb{C}) \to \mathcal{B} \otimes M_n(\mathbb{C}) \) are positive for every \( n \in \{1, 2, \ldots \} \).

**Theorem 2.5.** Quantum expectation is a completely positive operation. That is, the linear map \( \mathbb{E}_\nu : L^\infty(X,\mu) \boxtimes \mathcal{B} \to \mathcal{B} \) is a ucp map, for every quantum probability measure \( \nu \).

The following example shows that one can view \( \mathbb{E}_\nu[\psi] \) as a quantum averaging of \( \psi \). A version of this first appeared in [4]; see also Theorem 2.3(4) of [2].

**Example 2.6.** Let \( X = \{x_1, \ldots, x_n\} \) and let \( \mathcal{F}(X) \) be the power set of \( X \). If \( h_1, \ldots, h_n \in \mathcal{B}(\mathcal{H})_+ \) are such that \( h_1 + \cdots + h_n = 1 \in \mathcal{B}(\mathcal{H}) \), and \( \nu \) satisfies \( \nu(\{x_j\}) = h_j \) for \( j = 1, \ldots, n \), then for every \( \psi : X \to \mathcal{B}(\mathcal{H}) \),
\[ \mathbb{E}_\nu[\psi] = \int_X \psi \, d\nu = \sum_{j=1}^n h_j^{1/2} \psi(x_j)h_j^{1/2}. \]

3. **CONTINUITY OF QUANTUM EXPECTATION**

In this section we establish a natural quantum analogue of the classical dominated convergence theorem, namely Theorem 3.4 continuity of quantum expectation, along with some related results.

**Definition 3.1.** Let \( \psi : X \to \mathcal{B}(\mathcal{H}) \) and suppose that \( \{\psi_n\}_{n=1}^\infty \) is a sequence of quantum random variables. We say \( \psi_n \) converges ultraweakly \( \mu \)-almost surely to \( \psi \) if \( \text{Tr}(\rho \psi_n(x)) \to \text{Tr}(\rho \psi(x)) \) for all \( \rho \in S(\mathcal{H}) \) and \( \mu \)-almost all \( x \in X \).

It is an easy fact that the ultraweak \( \mu \)-almost sure limit \( \psi \) of the previous definition is itself a quantum random variable.

**Lemma 3.2.** Let \( \psi : X \to \mathcal{B}(\mathcal{H}) \) and suppose that \( \{\psi_n\}_{n=1}^\infty \) is a sequence of quantum random variables. If \( \psi_n \) converges ultraweakly \( \mu \)-almost surely to \( \psi \), then \( \psi \) is a quantum random variable.

**Proof.** Since \( \psi_n \) converges ultraweakly \( \mu \)-almost surely to \( \psi \), it follows that \( \text{Tr}(\rho \psi_n(x)) \to \text{Tr}(\rho \psi(x)) \) for all \( \rho \in S(\mathcal{H}) \) and \( \mu \)-almost all \( x \in X \). But since each \( \text{Tr}(\rho \psi_n(x)) \) is a complex valued random variable, the limit of the sequence \( \{\text{Tr}(\rho \psi_n(x))\}_{n=0}^\infty \) converges to a complex valued random variable, namely \( \text{Tr}(\rho \psi(x)) \) for each \( x \in X \), and therefore \( \psi \) is a quantum random variable. \( \square \)

**Lemma 3.3.** Let \( \{\psi_n\}_{n=1}^\infty \) be a sequence of quantum random variables. If \( \psi_n \) converges ultraweakly \( \mu \)-almost surely to \( \psi \), then \( \psi_n \boxtimes \frac{d\nu}{d\mu} \) converges ultraweakly \( \mu \)-almost surely to \( \psi \boxtimes \frac{d\nu}{d\mu} \).

**Proof.** For \( \rho \in S(\mathcal{H}) \) and \( x \in X \), let \( \tilde{\rho}_x = \left[ \text{Tr} \left( \frac{d\nu}{d\mu}(x) \right) \right]^{-1} \left( \frac{d\nu}{d\mu}(x) \right)^{1/2} \rho \left( \frac{d\nu}{d\mu}(x) \right)^{1/2} \), and notice that \( \tilde{\rho}_x \in S(\mathcal{H}) \). Therefore, using the assumption that \( \psi_n \) converges ultraweakly \( \mu \)-almost
surely to $\psi$ along with properties of the trace functional,

$$\lim_{n \to \infty} \operatorname{Tr} \left( \rho \left( \psi_n \otimes \frac{d\nu}{d\mu} \right)(x) \right) = \lim_{n \to \infty} \operatorname{Tr} \left( \rho \left( \frac{dr}{d\mu} (x) \right) \right) \operatorname{Tr}(\tilde{\rho}_x \psi_n(x)) = \operatorname{Tr} \left( \rho \left( \frac{dr}{d\mu} (x) \right) \right) \operatorname{Tr}(\tilde{\rho}_x \lim_{n \to \infty} \psi_n(x))$$

$$= \operatorname{Tr} \left( \rho \left( \frac{dr}{d\mu} (x) \right) \right) \operatorname{Tr}(\tilde{\rho}_x \psi(x)) = \operatorname{Tr} \left( \rho \left( \psi \otimes \frac{d\nu}{d\mu} \right) (x) \right)$$

as required. \qed

We now prove the main result of this section, namely continuity of quantum expectation.

**Theorem 3.4 (Continuity of Quantum Expectation).** Let $\psi : X \to \mathcal{B}(\mathcal{H})$. If $\{\psi_n\}_{n=1}^{\infty}$ is a sequence of $\nu$-integrable quantum random variables that converges ultraweakly $\mu$-almost surely to $\psi$, and if there exists a $\mu$-integrable random variable $Z : X \to \mathbb{C}$ such that

$$\left| \operatorname{Tr} \left( \rho \left( \psi_n \otimes \frac{d\nu}{d\mu} \right) \right) \right| \leq Z$$

almost surely for all $\rho \in S(\mathcal{H})$, then $\psi$ is $\nu$-integrable and $\mathbb{E}_\nu[\psi_n] \to \mathbb{E}_\nu[\psi]$ ultraweakly.

**Proof.** Begin by defining the sequence of complex valued random variables $\{\psi_n^{(n)}\}_{n=1}^{\infty}$ by $\psi_n^{(n)} = \operatorname{Tr} \left( \rho \left( \psi_n \otimes \frac{d\nu}{d\mu} \right) \right)$. Using properties of the trace functional along with Lemma 3.3, we obtain

$$\lim_{n \to \infty} \psi_n^{(n)} = \lim_{n \to \infty} \operatorname{Tr} \left( \rho \left( \psi_n \otimes \frac{d\nu}{d\mu} \right) \right) = \operatorname{Tr} \left( \rho \lim_{n \to \infty} \left( \psi_n \otimes \frac{d\nu}{d\mu} \right) \right) = \operatorname{Tr} \left( \rho \left( \psi \otimes \frac{d\nu}{d\mu} \right) \right).$$

That is, $\{\psi_n^{(n)}\}_{n=1}^{\infty}$ converges pointwise $\mu$-almost everywhere to $\operatorname{Tr} \left( \rho \left( \psi \otimes \frac{d\nu}{d\mu} \right) \right)$. By assumption, the sequence $\{\psi_n\}_{n=1}^{\infty}$ is bounded by a $\mu$-integrable random variable $Z : X \to \mathbb{C}$ so by Lebesgue’s dominated convergence theorem, $\operatorname{Tr} \left( \rho \left( \psi \otimes \frac{d\nu}{d\mu} \right) \right)$ is a $\mu$-integrable random variable, and for every $\rho \in S(\mathcal{H}),$

$$\int_X \operatorname{Tr} \left( \rho \left( \psi_n \otimes \frac{d\nu}{d\mu} \right) \right) d\mu \to \int_X \operatorname{Tr} \left( \rho \left( \psi \otimes \frac{d\nu}{d\mu} \right) \right) d\mu.$$

Therefore $\psi$ is a $\nu$-integrable function and $\operatorname{Tr}(\rho \mathbb{E}_\nu[\psi_n]) \to \operatorname{Tr}(\rho \mathbb{E}_\nu[\psi])$ which implies that $\mathbb{E}_\nu[\psi_n] \to \mathbb{E}_\nu[\psi]$ ultraweakly. \qed

As a first application of the continuity of quantum expectation we prove that, under certain conditions, quantum expectation is linear over infinite sums. In fact, this could even be considered as a special case of a quantum Fubini-type theorem.

**Theorem 3.5.** Suppose that $\{\psi_n\}_{n=1}^{\infty}$ is a sequence of $\nu$-integrable quantum random variables. If

$$\sum_{n=1}^{\infty} \psi_n = \lim_{N \to \infty} \sum_{n=1}^{N} \psi_n$$

exists where convergence is with respect to the ultraweak topology of $\mathcal{B}(\mathcal{H})$, then $\sum_{n=1}^{\infty} \psi_n$ is a $\nu$-integrable quantum random variable with $\mathbb{E}_\nu \left[ \sum_{n=1}^{\infty} \psi_n \right] = \sum_{n=1}^{\infty} \mathbb{E}_\nu[\psi_n].$

**Proof.** Let $\varphi_N = \sum_{n=1}^{N} \psi_n$ so that $\varphi_N$ converge ultraweakly $\mu$-almost surely to $\varphi$ where $\varphi = \sum_{n=1}^{\infty} \psi_n$. By Lemma 3.2, $\varphi$ is a quantum random variable, and by Theorem 3.4, $\varphi$ is $\nu$-integrable and

$$\lim_{N \to \infty} \mathbb{E}_\nu[\varphi_N] = \mathbb{E}_\nu[\varphi].$$
However, finite additivity of quantum expectation gives $E_\nu [\varphi_N] = E_\nu \left[ \sum_{n=1}^{N} \psi_n \right] = \sum_{j=1}^{N} E_\nu [\psi_n]$ so from (4) we obtain
\[
\sum_{n=1}^{\infty} E_\nu [\psi_n] = \lim_{N \to \infty} \sum_{n=1}^{N} E_\nu [\psi_n] = \lim_{N \to \infty} E_\nu [\varphi_N] = E_\nu [\varphi] = E_\nu \left[ \sum_{n=1}^{\infty} \psi_n \right]
\]
as required.

As an example of the type of calculations possible using the previous result, consider the following.

**Corollary 3.6.** If $\psi$ is an effect valued quantum random variable such that $\psi(x) \neq 0$ and $\psi(x) \neq 1$ for all $x \in X$, then $\sum_{n=1}^{\infty} E_\nu [\psi[1 - (1 + \psi^{-2})^{-1}]^n \psi] = 1$.

4. QUANTUM RANDOM VARIABLES WITH QUANTUM EXPECTATION ZERO

We will shortly prove a characterization theorem for quantum random variables with quantum expectation zero. As a preliminary tool, we need the following straightforward lemma.

**Lemma 4.1.** If $z \in B(\mathcal{H})_+$, then $\ker(z) = \ker(z^{1/2})$ and $\text{Ran}(z) = \text{Ran}(z^{1/2})$.

**Proof.** If $\eta \in \ker(z^{1/2})$, then $z^{1/2} \eta = 0$ implying that $z \eta = z^{1/2} z^{1/2} \eta = 0$ so $\eta \in \ker(z)$. Conversely, if $\eta \in \ker(z)$, then $z \eta = 0$ so that $0 = \langle z \eta, \eta \rangle = \langle z^{1/2} \eta, z^{1/2} \eta \rangle$ implying $z^{1/2} \eta = 0$ so $\eta \in \ker(z^{1/2})$. Since $z \in B(\mathcal{H})_+$ and $z = z^*$, it follows from the orthogonal decomposition $\mathcal{H} = \ker(z^*) \oplus \text{Ran}(z)$ that $\text{Ran}(z) = \text{Ran}(z^{1/2})$.

**Theorem 4.2.** If $\psi : X \to B(\mathcal{H})_+$ is a positive $\nu$-integrable quantum random variable, then the following statements are equivalent.

(A) $E_\nu [\psi] = 0$.

(B) $\text{Ran}(\psi(x)) \perp \text{Ran} \left( \frac{d\nu}{d\mu} (x) \right)$ for $\mu$-almost all $x \in X$.

(C) $\psi(x) \frac{d\nu}{d\mu} (x) = 0$ for $\mu$-almost all $x \in X$.

(D) $\left( \psi \boxtimes \frac{d\nu}{d\mu} \right) (x) = 0$ for $\mu$-almost all $x \in X$.

(E) $\psi(x)^{1/2} \left( \frac{d\nu}{d\mu} (x) \right)^{1/2} = 0$ for $\mu$-almost all $x \in X$.

**Proof.** Throughout the proof, let $z = z(x)$ be given by $z(x) = \psi(x)^{1/2} \left( \frac{d\nu}{d\mu} (x) \right)^{1/2}$, and note that $\psi(x) = \psi(x)^* \psi(x)$ since $\psi(x) \in B(\mathcal{H})_+$ for all $x \in X$. To show (E) $\iff$ (D), note that $z = 0$ if and only if $z^* z = 0$ and

(5) $\left( \psi \boxtimes \frac{d\nu}{d\mu} \right) (x) = \left( \frac{d\nu}{d\mu} (x) \right)^{1/2} \psi(x) \left( \frac{d\nu}{d\mu} (x) \right)^{1/2} = z^* z \geq 0$.

To show (A) $\implies$ (E) $\implies$ (C), suppose that $E_\nu [\psi] = 0$ which implies

(6) $\int_X \text{Tr} (\rho z^* z) \ d\mu = \int_X \text{Tr} \left( \rho \left( \frac{d\nu}{d\mu} (x) \right)^{1/2} \psi(x) \left( \frac{d\nu}{d\mu} (x) \right)^{1/2} \right) \ d\mu = \text{Tr}(\rho E_\nu [\psi]) = 0$

for every $\rho \in S(\mathcal{H})$. Since $z^* z \geq 0$, we deduce from (6) that $\text{Tr}(\rho z^* z) = 0$ for every $x \in X$ and $\rho \in S(\mathcal{H})$. Choosing $\rho = 1/d \in S(\mathcal{H})$ implies that $\text{Tr}(z^* z) = 0$, from which it follows that $z = 0$, namely
Proof. The fact that the implications (B) holds. Multiplying (E) on the left by $\psi(x)^{1/2}$ and on the right by $\left(\frac{d\nu}{d\mu}(x)\right)^{1/2}$ yields (C). To show $\iff (C) \rightarrow (D)$, note that if $\psi$ is any $\mathcal{B}(\mathcal{H})$ valued (and not just $\mathcal{B}(\mathcal{H})_+ \valued$) quantum random variable, then $\psi(x)^* \frac{d\nu}{d\mu}(x) = 0$ if and only if $\langle \xi, \psi(x)^* \frac{d\nu}{d\mu}(x) \eta \rangle = 0$ for all $\xi, \eta \in \mathcal{H}$ if and only if $\langle \psi(x)\xi, \frac{d\nu}{d\mu}(x) \eta \rangle = 0$ for all $\xi, \eta \in \mathcal{H}$ if and only if $\text{Ran}(\psi(x)) \perp \text{Ran}(\frac{d\nu}{d\mu}(x))$. That is, $\iff (C)$. Hence, if (C) holds, then Lemma 4.1 implies $\text{Ran}(\psi(x)) \perp \text{Ran}(\frac{d\nu}{d\mu}(x))^{1/2}$ and so from the already proved $\iff (C)$, we conclude $\psi(x)^* \left(\frac{d\nu}{d\mu}(x)\right)^{1/2} = 0$. Taking the adjoint of the previous equality and multiplying on the right by $\left(\frac{d\nu}{d\mu}(x)\right)^{1/2}$ yields (D) as desired. To complete the proof, we will show (D) $\Rightarrow (A)$. If $\psi$ is any $\mathcal{B}(\mathcal{H})$ valued (and not just $\mathcal{B}(\mathcal{H})_+ \valued$) quantum random variable for which (D) holds, then since $\mathbb{E}_\nu[\psi]$ is the unique operator with

$$\text{Tr}(\rho \mathbb{E}_\nu[\psi]) = \int_X \text{Tr}\left(\rho \left(\psi \otimes \frac{d\nu}{d\mu}\right)\right) \, d\mu = 0$$

for all $\rho \in S(\mathcal{H})$, we conclude $\mathbb{E}_\nu[\psi] = 0$ as required.

In the event that $\psi$ is a $\mathcal{B}(\mathcal{H})$ valued quantum random variable, as opposed to a $\mathcal{B}(\mathcal{H})_+ \valued$ one, the statements of the previous theorem are no longer all equivalent.

**Corollary 4.3.** Let $\psi : X \rightarrow \mathcal{B}(\mathcal{H})$ be a $\nu$-integrable quantum random variable and consider the following statements.

(A) $\mathbb{E}_\nu[\psi] = 0$.
(B) $\text{Ran}(\psi(x)) \perp \text{Ran}(\frac{d\nu}{d\mu}(x))$ for $\mu$-almost all $x \in X$.
(C) $\psi(x) \frac{d\nu}{d\mu}(x) = 0$ for $\mu$-almost all $x \in X$.
(D) $\left(\psi \otimes \frac{d\nu}{d\mu}\right)(x) = 0$ for $\mu$-almost all $x \in X$.

The following diagram describes the relationships between these statements.

$$\begin{align*}
\text{(B)} & \iff \text{(C)} \implies \text{(D)} \implies \text{(A)}
\end{align*}$$

Moreover, no other implications hold in general.

**Proof.** The fact that the implications (B) $\iff (C) \implies (D)$ and (D) $\implies (A)$ hold for $\mathcal{B}(\mathcal{H})$ valued quantum random variables was established in the proof of Theorem 4.2. To show that no other implications hold in general, we consider two examples. Let $X = \{x_1, x_2\}$, and consider the quantum probability measures $\nu_1$ and $\nu_2$ defined by

$$\nu_1(\{x_1\}) = \nu_1(\{x_2\}) = \left[ \begin{array}{cc} 1/2 & 0 \\ 0 & 1/2 \end{array} \right] \quad \text{and} \quad \nu_2(\{x_1\}) = \left[ \begin{array}{c} 1 \\ 0 \end{array} \right], \quad \nu_2(\{x_2\}) = \left[ \begin{array}{c} 0 \\ 1 \end{array} \right]$$

as well as the quantum random variables $\psi_1$ and $\psi_2$ defined by

$$\psi_1(x_1) = \left[ \begin{array}{c} 1 \\ 0 \end{array} \right], \quad \psi_1(x_2) = \left[ \begin{array}{c} -1 \\ 0 \end{array} \right] \quad \text{and} \quad \psi_2(x_1) = \left[ \begin{array}{c} 1 \\ 1 \end{array} \right], \quad \psi_2(x_2) = \left[ \begin{array}{c} 1 \\ 0 \end{array} \right].$$

Since $X$ is finite, the principal Radon-Nikodým derivative is easily computed, namely

$$\frac{d\nu_1}{d\mu_1}(x_j) = 2 \frac{\nu(\{x_j\})}{\text{Tr}(\nu(\{x_j\}))}.$$
for $i, j \in \{1, 2\}$. It is now easy to check that $\mathbb{E}_{\nu_1} [\psi_1] = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ although

$$\psi_1(x_1)^* \frac{d\nu_1}{d\mu_1}(x_1) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \psi_1(x_2)^* \frac{d\nu_1}{d\mu_1}(x_2) = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}$$

and

$$\left(\psi_1 \otimes \frac{d\nu_1}{d\mu_1}\right)(x_1) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \left(\psi_1 \otimes \frac{d\nu_1}{d\mu_1}\right)(x_2) = \begin{bmatrix} -1 & 0 \\ 0 & -1 \end{bmatrix}.$$ 

Hence, in this example (A) holds, but neither (C) nor (D) hold. Moreover, one can check that

$$\left(\psi_2 \otimes \frac{d\nu_2}{d\mu_2}\right)(x_1) = \left(\psi_2 \otimes \frac{d\nu_2}{d\mu_2}\right)(x_2) = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$$

whereas

$$\psi_2(x_1)^* \frac{d\nu_2}{d\mu_2}(x_1) = \begin{bmatrix} 0 & 0 \\ 2 & 0 \end{bmatrix} \quad \text{and} \quad \psi_2(x_2)^* \frac{d\nu_2}{d\mu_2}(x_2) = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}$$

providing an example for which (D) holds, but (C) does not hold. $\square$

**Corollary 4.4.** If $\psi : X \to \mathcal{B}(\mathcal{H})$ is a $\nu$-integrable quantum random variable and $\psi(x) \frac{d\nu}{d\mu}(x) = 0$ for $\mu$-almost all $x \in X$, then $\mathbb{E}_\nu [\psi] = 0$.

**Proof.** It follows from the implication (C) $\implies$ (A) of Corollary 4.3 that $\mathbb{E}_\nu [\psi^*] = 0$ and so $\mathbb{E}_\nu [\psi] = \mathbb{E}_\nu [\psi^*] = \mathbb{E}_\nu [\psi^*]^* = 0^* = 0$ as required. $\square$

5. A QUANTUM MARTINGALE CONVERGENCE THEOREM

In this section we establish a quantum martingale convergence theorem for quantum martingales obtained by conditioning on a fixed quantum random variable. Recall that a stochastic process \( \{M_j\}_{j=0}^\infty \) defined on a filtered probability space is a martingale with respect to the filtration \( \{\mathcal{F}_j\}_{j=0}^\infty \) if (i) $M_j$ is $\mathcal{F}_j$-measurable, (ii) $\mathbb{E}[|M_j|] < \infty$, and (iii) $M_j = \mathbb{E}[M_{j+1}|\mathcal{F}_j]$ for all $j$. The following version of the martingale convergence theorem is suitable for our purposes; see Theorem 3.7.3 of [1] for a proof.

**Theorem 5.1** (Martingale Convergence Theorem). If \( \{M_j\}_{j=0}^\infty \) is a martingale with respect to the filtration \( \{\mathcal{F}_j\}_{j=0}^\infty \) and there exists $C > 0$ such that $\mathbb{E}[|M_j|] < C$ for all $j$, then there exists a random variable $M_\infty$ such that $\mathbb{E}[|M_\infty|] < \infty$ and $M_j$ converges to $M_\infty$ almost surely.

When the martingale is obtained by conditioning on a fixed random variable, the martingale convergence theorem takes the following form; see Corollary 3.6.9 of [1].

**Corollary 5.2.** If $X$ is a random variable on the filtered probability space \( (\Omega, \mathcal{F}, \{\mathcal{F}_j\}_{j=1}^\infty, \mathbb{P}) \) and satisfies $\mathbb{E}[|X|] < \infty$, then the martingale $M_j = \mathbb{E}[X|\mathcal{F}_j]$ converges both almost surely and in $L^1(\Omega, \mathbb{P})$ to $M_\infty = \mathbb{E}[X|\mathcal{F}_\infty]$ where $\mathcal{F}_\infty = \sigma \left( \bigcup_{j=1}^\infty \mathcal{F}_j \right)$. If either (i) $X$ is $\mathcal{F}_\infty$-measurable, or (ii) $\mathcal{F}_\infty = \mathcal{F}$, then $M_\infty = X$.

We now turn our attention to quantum conditional expectation. The following result summarizes the relevant facts from [2] that we need; see, in particular, the proof of Theorem III.1.

**Theorem 5.3.** Suppose that $(X, \mathcal{O}(X), \nu)$ is a quantum probability space, and that $\psi : X \to \mathcal{B}(\mathcal{H})_+$ is a $\nu$-integrable quantum random variable with $\mathbb{E}_\nu [\psi] \neq 0$. If $\mathcal{F}(X)$ is a sub-$\sigma$-algebra of $\mathcal{O}(X)$, then there exists a function $\varphi : X \to \mathcal{B}(\mathcal{H})$ such that

(a) $\varphi$ is $\mathcal{F}(X)$-measurable,
(b) $\varphi$ is $\nu$-integrable, and
(c) $\mathbb{E}_\nu [\psi \chi E] = \mathbb{E}_\nu [\varphi \chi E]$ for every $E \in \mathcal{F}(X)$. 

We call $\varphi$ a version of quantum conditional expectation of $\psi$ given $\mathcal{F}(X)$ relative to $\nu$ and write $\varphi = \mathbb{E}_\nu[\psi|\mathcal{F}(X)]$. Moreover, if $\tilde{\varphi}$ is any other $\nu$-integrable $\mathcal{F}(X)$-measurable function satisfying $\mathbb{E}_\nu[\psi|E] = \mathbb{E}_\nu[\tilde{\varphi}|E]$ for every $E \in \mathcal{F}(X)$, then $\nu(\{x \in X : \varphi(x) \neq \tilde{\varphi}(x)\}) = 0$. Thus, instead of saying “$\varphi = \mathbb{E}_\nu[\psi|\mathcal{F}(X)]$ $\nu$-almost surely” we identify different versions and say that $\mathbb{E}_\nu[\psi|\mathcal{F}(X)]$ is the quantum conditional expectation of $\psi$ given $\mathcal{F}(X)$ relative to $\nu$. In fact, if $\nu' = \nu|_{\mathcal{F}(X)}$ is the restriction of $\nu$ to $\mathcal{F}(X)$, and $\tilde{\nu}(E) = \int_E \psi \, d\nu'$, for $E \in \mathcal{F}(X)$, then $\varphi = \mathbb{E}_\nu[\psi|\mathcal{F}(X)] = \frac{d\tilde{\nu}}{d\nu'}$. Clearly, $\varphi : X \to \mathcal{B}(\mathcal{H})_+$ for $\nu'$-almost all $x \in X$. Since $\nu'$-measure zero sets have $\nu$-measure zero, setting $\varphi(x) = \mathbb{E}_\nu[\psi|\mathcal{F}(X)](x) = \begin{cases} \frac{d\tilde{\nu}}{d\nu'}(x), & \text{for } \frac{d\tilde{\nu}}{d\nu'}(x) \in \mathcal{B}(\mathcal{H})_+, \\ 0, & \text{otherwise,} \end{cases}$ implies $\varphi : X \to \mathcal{B}(\mathcal{H})_+$ for all $x \in X$. We are now able to prove the important tower property for quantum conditional expectation. Note that this was not considered in [2].

**Theorem 5.4.** If $\psi : X \to \mathcal{B}(\mathcal{H})_+$ is a $\nu$-integrable quantum random variable with $\mathbb{E}_\nu[\psi] \neq 0$, and $\mathcal{F}(X)$, $\mathcal{G}(X)$ are sub $\sigma$-algebras of $\mathcal{O}(X)$ such that $\mathcal{F}(X) \subseteq \mathcal{G}(X)$, then

$$\mathbb{E}_\nu[\mathbb{E}_\nu[\psi|\mathcal{F}(X)]|\mathcal{G}(X)] = \mathbb{E}_\nu[\psi|\mathcal{G}(X)] = \mathbb{E}_\nu[\mathbb{E}_\nu[\psi|\mathcal{G}(X)]|\mathcal{F}(X)].$$

**Proof.** Define $\varphi_f = \mathbb{E}_\nu[\psi|\mathcal{F}(X)]$ and $\varphi_g = \mathbb{E}_\nu[\psi|\mathcal{G}(X)]$. To prove the theorem, we will verify that $\mathbb{E}_\nu[\varphi_f|\mathcal{G}(X)] = \varphi_f$ and $\mathbb{E}_\nu[\varphi_g|\mathcal{F}(X)] = \varphi_g$. The first equality in (7) follows immediately from the fact that $\varphi_f$ is $\mathcal{G}(X)$-measurable and $\mathcal{F}(X) \subseteq \mathcal{G}(X)$. As for the second equality in (7), observe that if $F \in \mathcal{F}(X)$ and $G \in \mathcal{G}(X)$, then $\mathbb{E}_\nu[\varphi_f \chi_F] = \mathbb{E}_\nu[\varphi_f \chi_G] = \mathbb{E}_\nu[\varphi_g \chi_G]$, implying $\mathbb{E}_\nu[\varphi_g \chi_F] = \mathbb{E}_\nu[\varphi_f \chi_G]$. This, in turn, implies that $\mathbb{E}_\nu[\varphi_f \chi_F] = \mathbb{E}_\nu[\varphi_g \chi_F]$ for any $F \in \mathcal{F}(X)$ yielding $\varphi_g = \varphi_f$ as required. \hfill $\square$

In analogy with the classical definition, we now state the definition of a quantum martingale.

**Definition 5.5.** Let $(X, \mathcal{O}(X), \nu)$ be a quantum probability space. A sequence of quantum random variables $\{\varphi_j\}_{j=0}^\infty$ is called a quantum martingale with respect to the filtration $\{\mathcal{F}_j(X)\}_{j=0}^\infty$ if

(a) $\varphi_j$ is $\mathcal{F}_j(X)$-measurable for all $j$,
(b) $\varphi_j$ is $\nu$-integrable for all $j$, and
(c) $\mathbb{E}_\nu[\varphi_{j+1} | \mathcal{F}_j(X)] = \varphi_j$ for all $j$.

It is also important to know that a quantum martingale is obtained by conditioning on a fixed quantum random variable.

**Theorem 5.6.** If $\psi : X \to \mathcal{B}(\mathcal{H})_+$ is a $\nu$-integrable quantum random variable and $\mathbb{E}_\nu[\psi] \neq 0$, then the sequence of $\mathcal{F}_j(X)$-measurable $\nu$-integrable quantum random variables $\{\varphi_j\}_{j=0}^\infty$ where $\varphi_j = \mathbb{E}_\nu[\psi|\mathcal{F}_j(X)]$ is a quantum martingale.

**Proof.** The fact that $\varphi_j$ is $\mathcal{F}_j(X)$-measurable follows immediately from the definition of conditional expectation. The fact that $\varphi_j$ is $\nu$-integrable follows since $\psi$ is $\nu$-integrable and $\mathbb{E}_\nu[\varphi_j] = \mathbb{E}_\nu[\mathbb{E}_\nu[\psi|\mathcal{F}_j(X)]] = \mathbb{E}_\nu[\psi]$; see Proposition 4.3 of [2] for a proof of this fact. We now observe that $\mathbb{E}_\nu[\varphi_{j+1} | \mathcal{F}_j(X)] = \mathbb{E}_\nu[\mathbb{E}_\nu[\psi|\mathcal{F}_{j+1}(X)]|\mathcal{F}_j(X)]$ and so from the tower property, Theorem 5.4, we have $\mathbb{E}_\nu[\mathbb{E}_\nu[\psi|\mathcal{F}_{j+1}(X)]|\mathcal{F}_j(X)] = \mathbb{E}_\nu[\psi|\mathcal{F}_j(X)] = \varphi_j$ as required. \hfill $\square$

**Theorem 5.7** (Continuity of Quantum Conditional Expectation). Let $(X, \mathcal{O}(X), \nu)$ be a quantum probability space and suppose that $\mathcal{F}(X) \subseteq \mathcal{O}(X)$ is a sub $\sigma$-algebra. Suppose further that $\{\psi_n\}_{n=0}^\infty$ is a sequence of $\nu$-integrable quantum random variables with $\psi_n : X \to \mathcal{B}(\mathcal{H})_+$ and $\mathbb{E}_\nu[\psi_n] \neq 0$ for all $n$. If $\psi_n$ converges ultraweakly $\mu$-almost surely to $\psi$, then $\mathbb{E}_\nu[\psi_n|\mathcal{F}(X)]$ converges ultraweakly $\mu$-almost surely to $\mathbb{E}_\nu[\psi|\mathcal{F}(X)]$. 
Proof. For any $F \in \mathcal{F}(X)$, we know $\psi_n X F$ converges ultraweakly $\mu$-almost surely to $\psi X F$. Theorem 3.4 says that $\mathbb{E}_\nu [\psi_n X F] \to \mathbb{E}_\nu [\psi X F]$ ultraweakly implying that $\mathbb{E}_\nu [\psi_n |F(X)|]$ converges ultraweakly $\mu$-almost surely to $\mathbb{E}_\nu [\psi |F(X)|]$ as required.

Our next preliminary result relates the quantum conditional expectation $\mathbb{E}_\nu [\psi |F(X)|]$ with the family of classical conditional expectations $\mathbb{E}_\mu [\psi |F(X)|]$ for $\rho \in \mathcal{S}(\mathcal{H})$.

**Proposition 5.8.** If $\psi : X \to \mathcal{B}(\mathcal{H})_+$ is a $\nu$-integrable quantum random variable with $\mathbb{E}_\nu [\psi] \neq 0$, then the following statements are equivalent.

1. $\mathbb{E}_\nu [\psi |F(X)|] = 1$.
2. $\mathbb{E}_\mu [\psi |F(X)|] = 1$ for every $\rho \in \mathcal{S}(\mathcal{H})$.

Proof. Let $\psi = \mathbb{E}_\nu [\psi |F(X)|]$ so that $\psi$ is a $\mathcal{F}(X)$-measurable quantum random variable with the property that $\mathbb{E}_\nu [\psi X E] = \mathbb{E}_\nu [\nu X E]$ for every $E \in \mathcal{F}(X)$. However, this holds if and only if for all $\rho \in \mathcal{S}(\mathcal{H})$ we have $\text{Tr}(\rho E [\psi X E]) = \text{Tr}(\rho E [\nu X E])$ which in turn holds if and only if $\mathbb{E}_\mu [\psi X E] = \mathbb{E}_\mu [\nu X E]$. Therefore, $\mathbb{E}_\mu [\psi |F(X)|]$.

We are now in a position to prove the main result of this paper, namely a quantum martingale convergence theorem for the quantum martingale $\varphi_j = \mathbb{E}_\nu [\psi |F_j(X)|]$. Although we will prove that the sequence $\{\varphi_j\}_{j=0}^\infty$ has a unique limit, in contrast to the classical situation, the value of the limiting random variable $\varphi_\infty$ cannot be determined in general. In fact, all that can be said is that $\varphi_\infty$ and $\mathbb{E}_\nu [\psi |F_\infty(X)|]$ differ by a quantum random variable $\Phi$ satisfying $\Phi = 0$ for all $\rho \in \mathcal{S}(\mathcal{H})$.

**Theorem 5.9** (Quantum Martingale Convergence Theorem). Let $(X, \mathcal{O}(X), \nu)$ be a quantum probability space with filtration $\{\mathcal{F}_j(X)\}_{j=0}^\infty$, and let $\psi : X \to \mathcal{B}(\mathcal{H})_+$ be a $\nu$-integrable quantum random variable with $\mathbb{E}_\nu [\psi] \neq 0$. Consider the quantum martingale $\varphi_j = \mathbb{E}_\nu [\psi |F_j(X)|]$. There exists a $\nu$-integrable quantum random variable $\varphi_\infty$ such that

1. $\varphi_j$ converges ultraweakly $\mu$-almost surely to $\varphi_\infty$.
2. $\varphi_\infty$ is $\mathcal{F}_\infty(X) = \sigma\left(\bigcup_{j=0}^\infty \mathcal{F}_j(X)\right)$-measurable, and
3. $\varphi_\infty \in \{\mathbb{E}_\nu [\psi] \mathcal{F}_\infty(X) + \mathcal{F} \mid \mathcal{F} = 0 \forall \rho \in \mathcal{S}(\mathcal{H})\}$.

Furthermore, if either

1. $\mathcal{F}_\infty(X) = \mathcal{O}(X)$, or
2. $\psi$ is $\mathcal{F}_\infty(X)$-measurable,
then $\varphi_\infty \in \{\psi + \Phi \mid \Phi = 0 \forall \rho \in \mathcal{S}(\mathcal{H})\}$.

Proof. For every $\rho \in \mathcal{S}(\mathcal{H})$, since $\varphi_j$ is $\nu$-integrable it follows that $\varphi_{j, \rho}$ is $\mu$-integrable and satisfies

$$\mathbb{E}_\mu [\varphi_{j, \rho}] = \mathbb{E}_\mu [\mathbb{E}_\mu [\psi |F_j(X)|]] \leq \mathbb{E}_\mu [\psi]$$

for all $j$. By the martingale convergence theorem, Theorem 5.1 for every $\rho \in \mathcal{S}(\mathcal{H})$ there exists a $\mu$-integrable $\varphi_{\infty, \rho}$ such that

1. $\varphi_{j, \rho}$ converges to $\varphi_{\infty, \rho}$ almost surely,
2. $\varphi_{\infty, \rho}$ is $\mathcal{F}_\infty(X) = \sigma\left(\bigcup_{j=0}^\infty \mathcal{F}_j(X)\right)$-measurable, and
3. $\varphi_{\infty, \rho} = \mathbb{E}_\mu [\psi |\mathcal{F}_\infty(X)|]$.

But this implies that $\varphi_j$ converges ultraweakly $\mu$-almost surely to some $\varphi_\infty$ with $\varphi_{\infty, \rho} = \varphi_{\infty, \rho}$ for all $\rho \in \mathcal{S}(\mathcal{H})$. By the continuity of quantum expectation, it follows that $\varphi_\infty$ is $\nu$-integrable. Let $\tilde{\varphi} = \mathbb{E}_\nu [\psi |\mathcal{F}_\infty(X)|]$ so that

$$\varphi_{\rho} \equiv \mathbb{E}_\mu [\psi |\mathcal{F}_\infty(X)|] = \varphi_{\infty, \rho} = \varphi_{\infty, \rho}.$$

However, if $\Phi$ is another $\nu$-integrable quantum random variable with $\Phi = 0$ for all $\rho \in \mathcal{S}(\mathcal{H})$, then $(\tilde{\varphi} + \Phi)_\rho = \tilde{\varphi}_\rho + \Phi = \varphi_{\infty, \rho}$ implying

$$\varphi_\infty \in \{\mathbb{E}_\nu [\psi |\mathcal{F}_\infty(X)|] + \Phi \mid \Phi = 0 \forall \rho \in \mathcal{S}(\mathcal{H})\}.$$
as claimed. Finally, if either $\mathcal{F}_\infty(X) = \mathcal{O}(X)$ or $\psi$ is $\mathcal{F}_\infty(X)$-measurable, then $E_\nu [\psi|\mathcal{F}_\infty(X)] = \psi$ so that $\varphi_\infty \in \{\psi + \Phi \mid \Phi_\rho = 0 \ \forall \rho \in S(\mathcal{H})\}$ as required.

We will now study the set of possible limits from our quantum martingale convergence theorem.

**Theorem 5.10.** Let $(X, \mathcal{O}(X), \nu)$ be a quantum probability space and let $\psi : X \to \mathcal{B}(\mathcal{H})_+$ be a $\nu$-integrable quantum random variable. Define the set

$$\Gamma_{\nu,\psi} = \{\Psi \mid \Psi = E_\nu [\psi|\mathcal{F}_\infty(X)] + \Phi \text{ with } \Phi_\rho = 0 \ \forall \rho \in S(\mathcal{H})\}.$$

If $\Psi_1 \in \Gamma_{\nu,\psi}$ then $\Psi_2 \in \Gamma_{\nu,\psi}$ if and only if $(\Psi_2 - \Psi_1) \boxtimes \frac{d\nu}{d\mu} = 0$.

**Proof.** Let $\Psi_1$, $\Psi_2 \in \Gamma_{\nu,\psi}$ so that $\Psi_{1,\rho} = \Psi_{2,\rho}$ for all $\rho \in S(\mathcal{H})$. Therefore,

$$0 = \text{Tr} \left( \rho \left( (\Psi_2 \boxtimes \frac{d\nu}{d\mu}) - \Psi_1 \boxtimes \frac{d\nu}{d\mu} \right) \right) = \text{Tr} \left( \rho \left( (\Psi_2 - \Psi_1) \boxtimes \frac{d\nu}{d\mu} \right) \right).$$

Since this equality holds for all $\rho \in S(\mathcal{H})$, it follows that $(\Psi_2 - \Psi_1) \boxtimes \frac{d\nu}{d\mu} = 0$ as required. Following the same reasoning in reverse gives the theorem. \qed

We can now use our results from Section 4 to study $\Gamma_{\nu,\psi}$. We know that if $\Phi$ is a quantum random variable then $\Phi_\rho = 0$ implies $E_\nu [\Phi] = 0$ whereas the converse is not necessarily true.

**Corollary 5.11.** If $\Sigma_{\nu,\psi} = \{\Psi \mid \Psi = E_\nu [\psi|\mathcal{F}_\infty(X)] + \Phi \text{, } E_\nu [\Phi] = 0\}$, then $\Gamma_{\nu,\psi} \subseteq \Sigma_{\nu,\psi}$.

**Proof.** Suppose that $\Psi \in \Gamma_{\nu,\psi}$. Then $\Psi = E_\nu [\psi|\mathcal{F}_\infty(X)] + \Phi$, where $\Phi_\rho = 0$ for all $\rho \in S(\mathcal{H})$. Then by the earlier remark, it follows that $E_\nu [\Phi] = 0$, so that $\Psi = E_\nu [\psi|\mathcal{F}_\infty(X)] + \Phi$ with $E_\nu [\Phi] = 0$. Hence $\Psi \in \Sigma_{\nu,\psi}$ and $\Gamma_{\nu,\psi} \subseteq \Sigma_{\nu,\psi}$ as required. \qed

ACKNOWLEDGEMENTS

Much of this research was done by the first author in his master’s thesis [5] under the supervision of the second author. The work of the second author is supported, in part, by the Natural Sciences and Engineering Research Council of Canada. The second author also thanks the Isaac Newton Institute for Mathematical Sciences, Cambridge, for its hospitality during the Random Geometry programme in Spring 2015 where the final writing of this paper was done. Finally, special thanks are due to both Doug Farenick and Sarah Plosker for many valuable discussions about this, and related, material.
