A Residue Formula for the Fundamental Hochschild 3-Cocycle for $SU_q(2)$

Ulrich Krähmer, Adam Rennie, and Roger Senior

Communicated by K. Schmückgen

Abstract. An analogue of a spectral triple over $SU_q(2)$ is constructed for which the usual assumption of bounded commutators with the Dirac operator fails. An analytic expression analogous to that for the Hochschild class of the Chern character for spectral triples yields a non-trivial twisted Hochschild 3-cocycle. The problems arising from the unbounded commutators are overcome by defining a residue functional using projections to cut down the Hilbert space.

Mathematics Subject Classification 2000: 19K33, 19K56, 20G42, 46L80, 46L87, 58B32, 58B34, 58J42, 58J20, 81R50.

Key Words and Phrases: Spectral triples, Dirac operators, cyclic cohomology, quantum groups, quantum $SU(2)$, residue formulas, Calabi-Yau algebras.

1. Introduction

This paper studies the homological dimension of the quantum group $SU_q(2)$ from the perspective of Connes’ spectral triples. We use an analogue of a spectral triple to construct, by a residue formula, a non-trivial Hochschild 3-cocycle. Thus we obtain finer dimension information than is provided by the nontriviality of a $K$-homology class, which is sensitive only to dimension modulo 2.

The position of quantum groups within noncommutative geometry has been studied intensively over the last 15 years. In particular, Chakraborty and Pal [ChP1] introduced a spectral triple for $SU_q(2)$, and this construction was subsequently refined in [DLSSV] and generalised by Neshveyev and Tuset in [NT2] to all compact Lie groups $G$. These spectral triples have analytic dimension $\dim G$ and nontrivial $K$-homology class. However, when Connes computed the Chern character for Chakraborty and Pal’s spectral triple [C1], he found that it had cohomological dimension 1 in the sense that the degree $\dim SU(2) = 3$ term in the local index formula is a Hochschild coboundary. Analogous results for the spectral triple from [DLSSV] were obtained in [DLSSV2].

Contrasting these ‘dimension drop’ results, Hadfield and the first author [HK1, HK2] showed that $SU_q(2)$ is a twisted Calabi-Yau algebra of dimension 3 whose twist is the inverse of the modular automorphism for the Haar state on this
compact quantum group, cf. Section 2. They also computed a cocycle representing a generator of the nontrivial degree 3 Hochschild cohomology groups (which we call the fundamental cocycle), and a dual degree 3 Hochschild cycle which we denote \( d_{vol} \).

The starting point of the present paper is the concept of a ‘modular’ spectral triple [CNNR]. These are analogous to ordinary spectral triples except for the use of twisted traces. The examples considered in [CNNR] arise from KMS states of circle actions on \( C^* \)-algebras, and yield nontrivial \( KK \)-classes with 1-dimensional Chern characters in twisted cyclic cohomology. In [KW] it was then shown that they also can be used to obtain the fundamental cocycle of the standard Podleś quantum 2-sphere.

Motivated by this, our construction here extends the modular spectral triple on the Podleś sphere to all of \( SU_q(2) \). This extension is not a modular spectral triple, but as our main theorem shows, still captures the homological dimension 3: we give a residue formula for a twisted Hochschild 3-cocycle which is a nonzero multiple of the fundamental cocycle. This is obtained by analogy with Connes’ formula for the Hochschild class of the Chern character of spectral triples, [C, Theorem 8, IV.2.\( \gamma \)] and [BeF, CPRS1]. A natural question that arises is whether our construction provides a representative of a nontrivial \( K \)-homology class.

The organisation of the paper is as follows. In Section 2 we recall the definitions of \( SU_q(2) \), the Haar state on \( SU_q(2) \) and the associated GNS representation, and finally the modular theory of the Haar state. In Section 3 we recall the homological constructions of [HK1, HK2], and prove some elementary results we will need when we come to show that our residue cocycle does indeed recover the class of the fundamental cocycle.

Section 4 contains all the key analytic results on meromorphic extensions of certain functions that allow us to prove novel summability type results for operators whose eigenvalues have mixed polynomial and exponential growth, see Lemma 4.2.

Section 5 constructs an analogue of a spectral triple \( (\mathcal{A}, \mathcal{H}, \mathcal{D}) \) over the algebra \( \mathcal{A} \) of polynomials in the standard generators of the \( C^* \)-algebra \( SU_q(2) \). The key requirement of bounded commutators fails, and this ‘spectral triple’ fails to be finitely summable in the usual sense (however, it is \( \theta \)-summable). Using an ultraviolet cutoff we can recover finite summability of the operator \( \mathcal{D} \) on a subspace of \( \mathcal{H} \) with respect to a suitable twisted trace. However, our representation of \( \mathcal{A} \) does not restrict to this subspace, and so we are prevented from obtaining a genuine spectral triple.

In Section 6 we define a residue functional \( \tau \). Heuristically, the value of \( \tau \) on an operator \( T \) is given by

\[
\tau(T) = \text{Res}_{s=3} \text{Trace}(\Delta^{-1}PT(1 + D^2)^{-s/2}).
\]

Here \( \Delta \) implements the modular automorphism of the Haar state, \( \mathcal{D} \) is our Dirac operator and \( P \) is a suitable projection that implements the cutoff. The existence, first of the trace, and then the residue, are both nontrivial matters. Also, as the referee has pointed out, there are other choices of projection which may be employed, and we say more about this in our concluding remarks.
The main properties of $\tau$ are described in Theorem 6.3, and in particular we show that the domain of $\tau$ contains the products of commutators $a_0[D,a_1][D,a_2][D,a_3]$ for $a_i \in \mathcal{A}$. In addition, $\tau$ is a twisted trace on a suitable subalgebra of the domain containing these products. The main result, Theorem 6.5, proves that the map $a_0,\ldots,a_3 \mapsto \tau(a_0[D,a_1][D,a_2][D,a_3])$ is a twisted Hochschild 3-cocycle, whose cohomology class is non-trivial and coincides with (a multiple of) the fundamental class.

**Acknowledgements** We would like to thank our colleagues Alan Carey, Victor Gayral, Jens Kaad, Andrzej Sitarz and Joe Várilly for stimulating discussions on these topics. The second and third authors were supported by the Australian Research Council. The first author was supported by the EPSRC fellowship EP/E/043267/1 and partially by the Polish Government Grant N201 1770 33 and the Marie Curie PIRSES-GA-2008-230836 network. Finally we thank the referee for a careful reading of the original manuscript which has led to improvements of the exposition.

2. Background on $SU_q(2)$

The notations and conventions of [KS] will be used throughout for consistency. We recall that $\mathcal{A} := \mathcal{O}(SU_q(2))$, for $q \in (0,1)$, is the unital Hopf $*$-algebra with generators $a,b,c,d$ satisfying the relations

\[
ab = qba, \quad ac = qca, \quad bd = qdb, \quad cd = qdc, \quad bc = cb
\]

\[
ad = 1 + qbc, \quad da = 1 + q^{-1}bc
\]

and carrying the usual Hopf structure, as in e.g. [KS]. The involution is given by

\[
a^* = d, \quad b^* = -qc, \quad c^* = -q^{-1}b, \quad d^* = a.
\]

We choose to view $\mathcal{A}$ as being generated by $a, b, c, d$ explicitly, rather than just $a, b$, in order to make formulae more readable.

**Proposition 2.1** ([KS, Proposition 4.4]). The set

\[\{a^mb^nc^rd^s \mid m,r,s \in \mathbb{N}_0, n \in \mathbb{N}\}\]

is a vector space basis of $\mathcal{A}$. These monomials will be referred to as the polynomial basis.

Recall that for each $l \in \frac{1}{2}\mathbb{N}_0$, there is a unique (up to unitary equivalence) irreducible corepresentation $V_l$ of the coalgebra $\mathcal{A}$ of dimension $2l+1$, and that $\mathcal{A}$ is cosemisimple. That is, if we fix a vector space basis in each of the $V_l$ and denote by $t_{l,j} \in \mathcal{A}$ the corresponding matrix coefficients, then we have the following analogue of the Peter-Weyl theorem.

**Theorem 2.2** ([KS, Theorem 4.13]). Let $I_l := \{-l,-l+1,\ldots,l-1,l\}$. Then the set $\{t_{l,r,s} \mid l \in \frac{1}{2}\mathbb{N}_0, r,s \in I_l\}$ is a vector space basis of $\mathcal{A}$. 
This will be referred to as the Peter-Weyl basis. With a suitable choice of basis in $V_1^2$, one has

$$a = t^{\frac{1}{2}}_{-\frac{1}{2}, -\frac{1}{2}}, \quad b = t^{\frac{1}{2}}_{\frac{1}{2}, -\frac{1}{2}}, \quad c = t^{\frac{1}{2}}_{\frac{1}{2}, \frac{1}{2}}, \quad d = t^{\frac{1}{2}}_{-\frac{1}{2}, \frac{1}{2}}.$$  

The expressions for the Peter-Weyl basis elements as linear combinations of the polynomial basis elements can be found in [KS, Section 4.2.4].

The quantized universal enveloping algebra $U_q(\mathfrak{sl}(2))$ is a Hopf algebra which is generated by $k, k^{-1}, e, f$ with relations

$$kk^{-1} = k^{-1}k = 1, \quad kek^{-1} = qe, \quad kfk^{-1} = q^{-1}f, \quad [e, f] = \frac{k^2 - k^{-2}}{q - q^{-1}}.$$  

Note that in [KS] this algebra is denoted by $\tilde{U}_q(\mathfrak{sl}_2)$ and $U^\text{ext}_q(\mathfrak{sl}_2)$. The algebra $U_q(\mathfrak{sl}(2))$ carries the following Hopf structure

$$\Delta(k) = k \otimes k, \quad \Delta(e) = e \otimes k + k^{-1} \otimes e, \quad \Delta(f) = f \otimes k + k^{-1} \otimes f$$

$$S(k) = k^{-1}, \quad S(e) = -qe, \quad S(f) = -q^{-1}f$$

$$\varepsilon(k) = 1, \quad \varepsilon(e) = \varepsilon(f) = 0.$$  

Adding the following involution

$$k^* = k, \quad e^* = f, \quad f^* = e,$$

we obtain a Hopf ∗-algebra which we denote by $U_q(\mathfrak{su}(2)).$

**Theorem 2.3** ([KS, Theorem 4.21]). There exists a unique dual pairing $\langle \cdot, \cdot \rangle$ of the Hopf algebras $U_q(\mathfrak{sl}(2))$ and $A$ such that

$$\langle k, a \rangle = q^{-\frac{1}{2}}, \quad \langle k, d \rangle = q^{\frac{1}{2}}, \quad \langle e, c \rangle = \langle f, b \rangle = 1$$

$$\langle k, b \rangle = \langle k, c \rangle = \langle e, a \rangle = \langle e, d \rangle = \langle e, b \rangle = \langle e, d \rangle = \langle f, a \rangle = \langle f, c \rangle = \langle f, d \rangle = 0.$$  

This pairing is compatible with the ∗-structures on $U_q(\mathfrak{sl}(2))$ and $A$.

The dual pairing between the Hopf algebras $\langle \cdot, \cdot \rangle : U_q(\mathfrak{sl}(2)) \times A \to \mathbb{C}$ defines left and right actions of $U_q(\mathfrak{sl}(2))$ on $A$. Using Sweedler notation ($\Delta(\alpha) = \sum \alpha_{(1)} \otimes \alpha_{(2)}$) these actions are given by

$$g \triangleright \alpha := \sum x_{(1)} \langle g, x_{(2)} \rangle \alpha \triangleleft g := \sum x_{(2)} \langle g, x_{(1)} \rangle, \quad \text{for all } \alpha \in A, \quad g \in U_q(\mathfrak{sl}(2)).$$

The left and right actions make $A$ a $U_q(\mathfrak{sl}(2))$-bimodule [KS, Proposition 1.16].

Our definition of the $q$-numbers is

$$[z]_q := \frac{q^{-z} - q^z}{q - q^{-1}} = Q(q^{-z} - q^z) \quad \text{for any } z \in \mathbb{C},$$  

where we abbreviated $Q := (q^{-1} - q)^{-1} \in (0, \infty)$. The following lemma recalls the explicit formulas for the action of the generators on the Peter-Weyl basis.
Lemma 2.4. For all $n \in \mathbb{Z}$,
\[
q^n t_{r,s}^l = q^{ns} t_{r,s}^l
\]
\[
e^{\epsilon} t_{r,s}^l = \sqrt{\left[l + \frac{1}{2}\right]q - \left[s + \frac{1}{2}\right]^2} t_{r,s}^{l+1}
\]
\[
f^{\epsilon} t_{r,s}^l = \sqrt{\left[l + \frac{1}{2}\right]q - \left[s - \frac{1}{2}\right]^2} t_{r,s}^{l-1}.
\]

Later we will use the notation
\[
\partial_k := k^{\epsilon}, \quad \partial_e := e^{\epsilon}, \quad \partial_f := f^{\epsilon},
\]
especially when we extend these operators from $A$ to suitable completions. Also observe that $\Delta(k^n) = k^n \otimes k^n$ for all $n \in \mathbb{Z}$, hence $k^n \epsilon$ and $\epsilon \cdot k^n$ are algebra automorphisms on $A$. They are not $\ast$-algebra automorphisms since for $\alpha \in A$ we have $(k \epsilon \alpha)^{\ast} = k^{-1} \epsilon \alpha^{\ast}$, $(\alpha \epsilon k)^{\ast} = \alpha^{\ast} \epsilon k^{-1}$. Finally, we introduce
\[
\partial_H(t_{r,s}^l) = s t_{r,s}^l,
\]
and we note that formally $\partial_k = q^{\partial n}$.

2.1. The GNS representation for the Haar state.

We denote by $A := C^\ast(SU_q(2))$ the universal $C^\ast$-completion of the $\ast$-algebra $A$ [KS, Section 4.3.4]. Let $h$ be the Haar state of $A$ whose values on basis elements are
\[
h(a b^n c^m) = h(d b^n c^m) = \delta_{j,0} \delta_{n,m} (-1)^m [m + 1]^{-1}_q, \quad h(t_{r,s}^l) = \delta_{l,0}.
\]

Let $\mathcal{H}_h$ denote the GNS space $L^2(A, h)$, where the inner product $\langle x, y \rangle = h(x^\ast y)$ is conjugate linear in the first variable. The representation of $A$ on $\mathcal{H}_h$ is induced by left multiplication in $A$. The set $\{t_{r,s}^l \mid l \in \frac{1}{2} \mathbb{N}_0, r, s \in I_l\}$ is an orthogonal basis for $\mathcal{H}_h$ with
\[
\langle t_{r,s}^l, t_{r',s'}^l \rangle = \delta_{l,l'} \delta_{r,r'} \delta_{s,s'} q^{-2r} [2l + 1]^{-1}_q.
\]

2.2. Modular Theory. Following Woronowicz, we call the automorphism
\[
\vartheta(\alpha) := k^{-2} \epsilon \alpha \epsilon k^{-2}, \quad \alpha \in \mathcal{A}
\]
the modular automorphism of $\mathcal{A}$. The action of $\vartheta$ on the generators of $\mathcal{A}$ and the Peter-Weyl basis is given by
\[
\vartheta(a) = q^2 a, \quad \vartheta(b) = b, \quad \vartheta(c) = c, \quad \vartheta(d) = q^{-2}d, \quad \vartheta(t_{r,s}^l) = q^{-2(r+s)} t_{r,s}^l.
\]

The modular automorphism is a (non $\ast$-) algebra automorphism; more precisely for any $\alpha \in \mathcal{A}$
\[
\vartheta(\alpha)^{\ast} = \vartheta^{-1}(\alpha^{\ast}).
\]

The Haar state is related to the modular automorphism by the following proposition.

Proposition 2.5 ([KS, Proposition 4.15]). For $\alpha, \beta \in \mathcal{A}$, we have
\[
h(\alpha \beta) = h(\vartheta(\beta) \alpha).
\]
In fact, \( h \) extends to a KMS state on \( A \) for the strongly continuous one-parameter group \( \vartheta_w, w \in \mathbb{R} \), of \(*\)-automorphisms of \( A \) which is given on the generators by
\[
\vartheta_w(a) := q^{-2iw}a, \quad \vartheta_w(b) := b, \quad \vartheta_w(c) := c, \quad \vartheta_w(d) := q^{2iw}d.
\]

We extend this to an action \( \vartheta : \mathbb{C} \times A \to A \) by algebra (not \(*\)) automorphisms that is defined on generators by
\[
\vartheta_z(a) := q^{-2iz}a, \quad \vartheta_z(b) := b, \quad \vartheta_z(c) := c, \quad \vartheta_z(d) := q^{2iz}d,
\]
so that the modular automorphism \( \vartheta \) is \( \vartheta_i \).

We can implement \( \vartheta_w \) in the GNS representation on \( \mathcal{H}_h \). To do this, we define an unbounded linear operator \( \Delta F \) on \( A \subset \mathcal{H}_h \) by
\[
\Delta F(t_{r,s}) := q^{2r+2s}t_{r,s}
\]
and call this the full modular operator. Then we have
\[
\vartheta_w(x)\xi = \Delta^{iw} F_x \Delta^{-iw} F \xi, \quad \text{for all } x \in A \text{ and } \xi \in \mathcal{H}_h.
\]

The subscript \( F \) denotes that this operator is associated to the full modular automorphism \( \vartheta \). In addition, we define the left and the right modular operators on \( A \subset \mathcal{H}_h \) by
\[
\Delta_L(t_{r,s}) := q^{2s}t_{r,s}, \quad \Delta_R(t_{r,s}) := q^{2r}t_{r,s},
\]
so \( \Delta_F = \Delta_L \Delta_R = \Delta_R \Delta_L \). Just as \( \Delta_F \) implements the modular automorphism group, the left and right modular operators implement one-parameter groups of automorphisms of \( A \):
\[
\sigma_{L,w}(t_{r,s}) = q^{2iws}t_{r,s} = \Delta^{iw}_L t_{r,s} \Delta^{-iw}_L, \quad \sigma_{R,w}(t_{r,s}) = q^{2irw}t_{r,s} = \Delta^{iw}_R t_{r,s} \Delta^{-iw}_R.
\]

As with the full action, the left and right actions are periodic and hence give rise to actions of \( \mathbb{T} \) on \( A \). These may be extended to a complex action on the \(*\)-subalgebra \( A \) which we will denote \( \sigma_{L,z} \) and \( \sigma_{R,z} \). In particular, we obtain for \( z = i \) the algebra automorphisms
\[
\sigma_L := k^{-2} \cdot, \quad \sigma_R := k^{-2} \cdot
\]
\[
\vartheta = \sigma_L \sigma_R = \sigma_R \sigma_L, \quad \vartheta(\alpha)\xi = \Delta^{1}_F \alpha \Delta_F \xi,
\]
\[
\sigma_L(t_{r,s}) = q^{-2s}t_{r,s}, \quad \sigma_R(t_{r,s}) = q^{-2r}t_{r,s},
\]
\[
\sigma_L(\alpha)\xi = \Delta^{-1}_L \alpha \Delta_L \xi, \quad \sigma_R(\alpha)\xi = \Delta^{-1}_R \alpha \Delta_R \xi.
\]

The fixed point algebra for the left action on \( A \) is isomorphic to the standard Podleś quantum 2–sphere \( \mathcal{O}(S^2_q) \). We will denote its \( C^* \)-completion by \( B \). As the left action is periodic, we may define a positive faithful expectation \( \Phi : A \to B \) by
\[
\Phi(x) = \frac{\ln(q^{-2})}{2\pi} \int_0^{2\pi/\ln(q^{-2})} \sigma_{L,w}(x)dw.
\]
More generally, given $n \in \mathbb{Z}$ and $x \in A$ we define
\[
\Phi_n(x) = \frac{\ln(q^{-2})}{2\pi} \int_0^{2\pi/\ln(q^{-2})} q^{-inw} \sigma_{L,w}(x) dw.
\]

Since $\sigma_{L,w}$ is a strongly continuous action on $A$, the $\Phi_n$ are continuous maps on $A$. Observe that $\Phi = \Phi_0$ and
\[
\Phi_n(t_{r,s}^l) = \delta_{n,2s} t_{r,s}^l.
\]

Hence the $\Phi_n$ can be extended to bounded operators on the GNS space $H_h$, and in fact the $\Phi_n$ are projections onto the spectral subspaces of the left circle action. So we make explicit the decomposition of $A$ into the left spectral subspaces by defining
\[
B_n := \Phi_n(A) = \{ \alpha \in A \mid \sigma_{L,w}(\alpha) = q^{2inw} \alpha \} \quad \text{and} \quad H_n := L^2(B_n, h)
\]
where $h$ is the Haar state (restricted to $B_n$). This leads to the following decomposition for the GNS space
\[
H_h = \bigoplus_{n=-\infty}^{\infty} H_n.
\]

The commutation relations for the projections $\Phi_n$ and the operators $\partial_k$, $\partial_e$ and $\partial_f$ are found from the definitions on the Peter-Weyl basis to be
\[
\partial_k \Phi_n = \Phi_n \partial_k = q^{n} \Phi_n \quad \partial_H \Phi_n = \Phi_n \partial_H = \frac{n}{2} \Phi_n \quad \Delta_L \Phi_n = \Phi_n \Delta_L = q^n \Phi_n
\]
\[
\partial_e \Phi_n = \Phi_{n+2} \partial_e \quad \partial_f \Phi_n = \Phi_{n-2} \partial_f.
\]

The left actions of $e$ and $f$ are twisted derivations in the sense that for $\alpha, \beta \in A$ we have
\[
\partial_e(\alpha \beta) = \partial_e(\alpha) \partial_k(\beta) + \partial_k^{-1}(\alpha) \partial_e(\beta),
\]
\[
\partial_f(\alpha \beta) = \partial_f(\alpha) \partial_k(\beta) + \partial_k^{-1}(\alpha) \partial_f(\beta).
\]

More generally, given $\alpha \in A$ and $\xi \in H_h$
\[
\partial_e(\alpha \xi) = \partial_e(\alpha) \Delta^\frac{1}{2}_L \xi + \sigma^\frac{1}{2}_L(\alpha) \partial_e(\xi) \quad \partial_f(\alpha \xi) = \partial_f(\alpha) \Delta^\frac{1}{2}_L \xi + \sigma^\frac{1}{2}_L(\alpha) \partial_f(\xi)
\]
\[
= \partial_e(\alpha) \Delta^\frac{1}{2}_L \xi + \Delta^{-\frac{1}{2}}_L \alpha \Delta^\frac{1}{2}_L \partial_e(\xi) \quad = \partial_f(\alpha) \Delta^\frac{1}{2}_L \xi + \Delta^{-\frac{1}{2}}_L \alpha \Delta^\frac{1}{2}_L \partial_f(\xi).
\]

See e.g. [BHMS] and the references therein for background on the generalisation of this setting in terms of Hopf-Galois extensions.

3. Twisted homology and cohomology

We recall that the algebra $A$ is a $\psi^{-1}$-twisted Calabi-Yau algebra of dimension 3, see [HK2] and the references therein for this result and some background. Since the centre of $A$ consists only of the scalar multiples of $1_A$, this means in particular that
the cochain complex $C^\bullet := \text{Hom}_\mathbb{C}(A^{\otimes \bullet + 1}, \mathbb{C})$, with differential $b_{\vartheta^{-1}} : C^n \to C^{n+1}$ given by

$$(b_{\vartheta^{-1}} \varphi)(a_0, \ldots, a_n, a_{n+1}) = \sum_{i=0}^{n} (-1)^i \varphi(a_0, \ldots, a_i a_{i+1}, \ldots, a_n),$$

is exact in degrees $n > 3$ and has third cohomology $H^3(C, b_{\vartheta^{-1}}) \cong \mathbb{C}$. An explicit cocycle whose cohomology class generates $H^3(C, b_{\vartheta^{-1}})$ can be constructed using the following incarnation of the cup product $\smile$ in Hochschild cohomology:

**Lemma 3.1.** Let $\sigma_0, \ldots, \sigma_3$ be automorphisms of $A$, $\int : A \to \mathbb{C}$ be a $\sigma_0 \circ \vartheta^{-1} \circ \sigma_3^{-1}$-twisted trace, that is,

$$\int \alpha \beta = \int \sigma_0(\vartheta^{-1}(\sigma_3^{-1}(\beta)))\alpha,$$

and $\partial_p : A \to A$, $p = 1, 2, 3$, be $\sigma_{p-1}$-$\sigma_p$-twisted derivations, that is,

$$\partial_p(\alpha \beta) = \sigma_{p-1}(\alpha)\partial_p(\beta) + \partial_p(\alpha)\sigma_p(\beta).$$

Then the functional defined via the cup product by

$$\left( \int \ominus_1 \ominus_2 \ominus_3 \right)(a_0, a_1, a_2, a_3) := \int \sigma_0(a_0)\partial_1(a_1)\partial_2(a_2)\partial_3(a_3)$$

is a $\vartheta^{-1}$-twisted cocycle, $b_{\vartheta^{-1}}(\int \ominus_1 \ominus_2 \ominus_3) = 0$.

**Proof.** This is a straightforward computation:

$$\left( b_{\vartheta^{-1}} \int \ominus_1 \ominus_2 \ominus_3 \right)(a_0, a_1, a_2, a_3, a_4)$$

$$= \int \sigma_0(a_0 a_1)\partial_1(a_2)\partial_2(a_3)\partial_3(a_4) - \int \sigma_0(a_0)\partial_1(a_1 a_2)\partial_2(a_3)\partial_3(a_4)$$

$$+ \int \sigma_0(a_0)\partial_1(a_1)\partial_2(a_2 a_3)\partial_3(a_4) - \int \sigma_0(a_0)\partial_1(a_1)\partial_2(a_2)\partial_3(a_3 a_4)$$

$$+ \int \sigma_0(\vartheta^{-1}(a_4) a_0)\partial_1(a_1)\partial_2(a_2)\partial_3(a_3)$$

$$= - \int \sigma_0(a_0)\partial_1(a_1)\partial_2(a_2)\partial_3(a_3)\sigma_3(a_4) + \int \sigma_0(\vartheta^{-1}(a_4))\sigma_0(a_0)\partial_1(a_1)\partial_2(a_2)\partial_3(a_3)$$

$$= 0. \quad \blacksquare$$

Less straightforward is that when applying the above result with

$$\sigma_0 = \sigma_1 = k^{-4} \circ \cdots, \quad \sigma_2 = k^{-2} \circ \cdots, \quad \sigma_3 = \text{id},$$

$$\partial_1 = (k^{-4} \circ \cdots) \circ \partial_H, \quad \partial_2 = (k^{-3} \circ \cdots) \circ \partial_e, \quad \partial_3 = (k^{-1} \circ \cdots) \circ \partial_f$$

and a suitable twisted trace, one obtains a cohomologically nontrivial $\vartheta^{-1}$-twisted cocycle.
Lemma 3.2 ([HK2, Corollary 3.8]). Define a linear functional \( f_{[1]} : \mathcal{A} \rightarrow \mathbb{C} \) by
\[
\int_{[1]} a^m b^n c^r := \delta_{m,0} \delta_{n,0} \delta_{r,0}, \quad \int_{[1]} b^m c^r d^s := \delta_{m,0} \delta_{r,0} \delta_{s,0}.
\]
Then \( f_{[1]} \) is a \( \sigma_L^2 \circ \vartheta^{-1} \)-twisted trace, and the cochain \( \varphi \in C^3 \) given by
\[
\varphi(a_0, \ldots, a_3) = \int_{[1]} (k^{-4} \triangleright (a_0 \partial_H(a_1))) (k^{-3} \triangleright \partial_c(a_2)) (k^{-1} \triangleright \partial_f(a_3))
\]
is a cocycle, \( b_{\vartheta^{-1}} \varphi = 0 \), whose cohomology class is nontrivial, \( \varphi \notin \text{im} b_{\vartheta^{-1}} \).

Later, we will also have to consider the cocycles that are obtained by using the (twisted) derivations \( \partial_H, \partial_c, \partial_f \) in a different order. Explicitly, this is handled by the following result.

Lemma 3.3. In the situation of Lemma 3.1, define
\[
\tilde{\delta}_3 = \sigma_1 \circ \sigma_2^{-1} \circ \partial_3, \quad \tilde{\delta}_2 := \partial_2 \circ \sigma_2^{-1} \circ \sigma_3, \quad \tilde{\delta}_2 := \sigma_0 \circ \sigma_1^{-1} \circ \partial_2, \quad \tilde{\delta}_1 := \partial_1 \circ \sigma_1^{-1} \circ \sigma_2.
\]
Then we have
\[
\int \vartheta \partial_1 \vartheta \partial_2 \vartheta \partial_3 + \int \vartheta \partial_1 \vartheta \partial_3 \vartheta \partial_2 = b_{\vartheta^{-1}} \psi_{132},
\]
\[
\int \vartheta \partial_1 \vartheta \partial_2 \vartheta \partial_3 + \int \vartheta \partial_2 \vartheta \partial_1 \vartheta \partial_3 = b_{\vartheta^{-1}} \psi_{213},
\]
where
\[
\psi_{132}(a_0, a_1, a_2) := \int \sigma_0(a_0) \partial_1(a_1) \partial_2(\sigma_2^{-1}(\partial_3(a_2))),
\]
\[
\psi_{213}(a_0, a_1, a_2) := - \int \sigma_0(a_0) \partial_1(\sigma_1^{-1}(\partial_2(a_1))) \partial_3(a_2).
\]

Proof. Straightforward computation.

Applying Lemma 3.3 repeatedly to the cocycle \( \varphi \) from Lemma 3.2 gives cohomologous cocycles.

Corollary 3.4. The cocycle \( \varphi \) from Lemma 3.2 is cohomologous to each of
\[
\varphi_{132}(a_0, a_1, a_2, a_3) := -q^{-2} \int_{[1]} (k^{-4} \triangleright (a_0 \partial_H(a_1))) (k^{-3} \triangleright \partial_f(a_2)) (k^{-1} \triangleright \partial_c(a_3)),
\]
\[
\varphi_{213}(a_0, a_1, a_2, a_3) := - \int_{[1]} (k^{-4} \triangleright a_0) (k^{-3} \triangleright \partial_c(a_1)) (k^{-2} \triangleright \partial_H(a_2)) (k^{-1} \triangleright \partial_f(a_3)),
\]
\[
\varphi_{312}(a_0, a_1, a_2, a_3) := q^{-2} \int_{[1]} (k^{-4} \triangleright a_0) (k^{-3} \triangleright \partial_f(a_1)) (k^{-2} \triangleright \partial_H(a_2)) (k^{-1} \triangleright \partial_c(a_3)),
\]
\[ \varphi_{231}(a_0,a_1,a_2,a_3) := \int_{[1]} (k^{-4} \triangleright a_0) (k^{-3} \triangleright \partial_\epsilon(a_1)) (k^{-1} \triangleright \partial_f(a_2)) (\partial_H(a_3)) \]
and
\[ \varphi_{321}(a_0,a_1,a_2,a_3) := -q^{-2} \int_{[1]} (k^{-4} \triangleright a_0) (k^{-3} \triangleright \partial_f(a_1)) (k^{-1} \triangleright \partial_\epsilon(a_2)) (\partial_H(a_3)). \]

**Proof.** To begin, one applies Lemma 3.3 to \( \varphi \) with
\[ \hat{\partial}_3 = (k^{-3} \triangleright \cdot) \circ \partial_f, \quad \hat{\partial}_2 = (k^{-3} \triangleright \cdot) \circ \partial_\epsilon \circ (k^2 \triangleright \cdot), \]
\[ \hat{\partial}_1 := (k^{-4} \triangleright \cdot) \circ \partial_H(\cdot) \circ (k^2 \triangleright \cdot). \]
The formulae for these derivations can be simplified by commuting \( \partial_\epsilon \) and \( k \triangleright \) to obtain
\[ \tilde{\partial}_3 = (k^{-3} \triangleright \cdot) \circ \partial_f, \quad \tilde{\partial}_2 = q^{-2}(k^{-1} \triangleright \cdot) \circ \partial_\epsilon, \quad \tilde{\partial}_2 = (k^{-3} \triangleright \cdot) \circ \partial_\epsilon, \quad \tilde{\partial}_1 := (k^{-2} \triangleright \cdot) \circ \partial_H(\cdot). \]
This gives \( \varphi_{132} \) and \( \varphi_{213} \). Then we can apply Lemma 3.3 again to \( \varphi_{213} \). Going from \( \varphi_{213} \) to \( \varphi_{312} \) is easy, since it only involves exchanging \( e \) and \( f \). Next we obtain \( \varphi_{231} \) from \( \varphi_{213} \) by applying Lemma 3.3 with
\[ \sigma_0 = k^{-4} \triangleright \cdot, \quad \sigma_1 = \sigma_2 = k^{-2} \triangleright \cdot, \quad \sigma_3 = \text{id}, \]
\[ \partial_1 = (k^{-3} \triangleright \cdot) \circ \partial_\epsilon, \quad \partial_2 = (k^{-2} \triangleright \cdot) \circ \partial_H, \quad \partial_3 = (k^{-1} \triangleright \cdot) \circ \partial_f \]
which gives
\[ \tilde{\partial}_3 = \sigma_1 \circ \sigma_2^{-1} \circ \partial_3 = (k^{-1} \triangleright \cdot) \circ \partial_f, \]
\[ \tilde{\partial}_2 = \partial_2 \circ \sigma_2^{-1} \circ \sigma_3 = (k^{-2} \triangleright \cdot) \circ \partial_H \circ (k^2 \triangleright \cdot) = \partial_H. \]

The last cocycle is obtained analogously from \( \varphi_{312} \).

A homologically nontrivial 3-cycle \( d\text{vol} \) in the (pre)dual chain complex \( C_* := A \otimes \mathcal{C}^{**1} \) (with differential dual to \( b_{\partial-1} \)) has been computed in [HK1, HK2]:

\[
d\text{vol} := d \otimes a \otimes b \otimes c - d \otimes a \otimes c \otimes b + q \, d \otimes c \otimes a \otimes b \\
- q^2 \, d \otimes c \otimes b \otimes a + q^2 \, d \otimes b \otimes c \otimes a - q \, d \otimes b \otimes a \otimes c \\
+ c \otimes b \otimes a \otimes d - c \otimes b \otimes d \otimes a + q \, c \otimes d \otimes b \otimes a \\
- c \otimes d \otimes a \otimes b + c \otimes a \otimes d \otimes b - q^{-1} \, c \otimes a \otimes b \otimes d \\
+ (q^{-1} - q) \, c \otimes b \otimes c \otimes b \tag{2}
\]

With this normalisation, we have \( \varphi(d\text{vol}) = 1 \).
4. Some meromorphic functions

In this section we demonstrate that certain functions have meromorphic continuations. These functions arise in the residue formula for the Hochschild cocycle in the next two sections. We require the following notation. For any \( l \in \frac{1}{2} \mathbb{N}_0 \) and \(-(2l+1) \leq n \leq (2l+1)\) define

\[
\lambda_{l,n} := \sqrt{(\frac{n}{2})^2 + q^n \left( \left( l + \frac{1}{2} \right)_q^2 - \left( \frac{n}{2} \right)_q^2 \right)}.
\] (3)

We also define the finite sets

\[
\mathcal{J}_l := \begin{cases} 
\{0, 2, \ldots, 2l - 1\} & l \in (\mathbb{N}_0 + \frac{1}{2}) \\
\{1, 3, \ldots, 2l - 1\} & l \in \mathbb{N}
\end{cases}
\]

Finally, we remark that in this section we will use \( t \) as a real parameter instead of a Peter-Weyl basis element.

**Lemma 4.1.** The formulas

\[
z \mapsto f_1(z) := \sum_{2l=1}^{\infty} \sum_{r=-l}^{l} \sum_{n \in \mathcal{J}_l} \frac{q^{2l-2r}}{(1 + \lambda_{l,n}^2)^{z/2}}
\]

\[
z \mapsto f_2(z) := \sum_{2l=1}^{\infty} \sum_{r=-l}^{l} \sum_{n \in \mathcal{J}_l} \frac{q^{2l-n}}{(1 + \lambda_{l,n}^2)^{z/2}}
\]

define holomorphic functions on \( \text{Dom}_2 \), where we abbreviate

\[
\text{Dom}_t := \{z \in \mathbb{C} | \text{Re}(z) > t\}, \quad t \in \mathbb{R}.
\]

**Proof.** We will show that the sums converge uniformly on compacta. To begin with, we take \( z = t \in (2, \infty) \), and compute the summation over the \( r \) parameter for \( f_1 \) and \( f_2 \) giving

\[
f_1(t) = \sum_{2l=1}^{\infty} \sum_{n \in \mathcal{J}_l} \frac{q^{2l[2l+1]}_q}{(1 + \lambda_{l,n}^2)^{t/2}}, \quad \quad f_2(t) = \sum_{2l=1}^{\infty} \sum_{n \in \mathcal{J}_l} \frac{(2l + 1)q^{2l-n}}{(1 + \lambda_{l,n}^2)^{t/2}}.
\] (4)

For \( l \in \frac{1}{2} \mathbb{N}_0 \) and \( n \in \mathcal{J}_l \) we have the inequality

\[
\left( l + \frac{1}{2} \right)_q^2 - \left( \frac{n}{2} \right)_q^2 \geq [2l]_q
\]

with equality attained for \( n = 2l - 1 \). This inequality implies

\[
1 + \lambda_{l,n}^2 \geq 1 + \left( \frac{n}{2} \right)_q^2 + q^n[2l]_q \geq 1 + \left( \frac{n}{2} \right)_q^2 + q^{n-2l+1}.
\] (5)
Since the summands in Equation (4) are positive, we may invoke Tonelli’s theorem to rearrange the order of summation

\[ \sum_{2l=1}^{\infty} \sum_{n \in J_l} \to \sum_{n=0}^{\infty} \sum_{l=(n+1)/2}^{\infty}. \]

Combining the elementary inequality \( q^{2l} [2l + 1] q \leq q^{-1} Q \) with Equation (5) gives the inequalities

\[ f_1(t) \leq q^{-1} Q \sum_{n=0}^{\infty} \sum_{l=\frac{n+1}{2}}^{\infty} \frac{1}{(1 + (\frac{n}{2})^2 + q^{n-2l+1})^{1/2}}, \]

\[ f_2(t) \leq \sum_{n=0}^{\infty} \sum_{l=\frac{n+1}{2}}^{\infty} \frac{(2l + 1) q^{2l-n}}{(1 + (\frac{n}{2})^2 + q^{n-2l+1})^{1/2}}. \]

We reparameterise the sums defining \( f_1 \) and \( f_2 \) using \( y = 2l - 1 - n \) with summation range \( y = 0 \) to \( y = \infty \). This yields

\[ f_1(t) \leq q^{-1} Q \sum_{n=0}^{\infty} \sum_{y=0}^{\infty} \frac{1}{(1 + (\frac{n}{2})^2 + q^{-y})^{1/2}}, \]

\[ f_2(t) \leq \sum_{n=0}^{\infty} \sum_{y=0}^{\infty} \frac{(y + n + 2) q^{y+1}}{(1 + (\frac{n}{2})^2 + q^{-y})^{1/2}}. \] (6)

Next we employ the inequality \( \alpha^2 + \beta^2 \geq \alpha \beta \), valid for any positive real numbers \( \alpha \) and \( \beta \), to \( f_1(t) \). This yields

\[ f_1(t) \leq q^{-1} Q \sum_{n=0}^{\infty} \sum_{y=0}^{\infty} q^{yt/4} \left( 1 + \left( \frac{n}{2} \right)^2 \right)^{-t/4} < \infty \quad \text{for all } t > 2. \]

For the function \( f_2(t) \), we evaluate the sums over \( y \) on the right hand side to obtain, for some positive constants \( C_1 \) and \( C_2 \),

\[ f_2(t) \leq \sum_{n=0}^{\infty} \sum_{y=0}^{\infty} \frac{(y + n + 2) q^{y+1}}{(1 + (\frac{n}{2})^2)^{t/2}} = \sum_{n=0}^{\infty} \frac{C_1 + C_2 n}{(1 + (\frac{n}{2})^2)^{t/2}}. \]

This last sum is finite for all \( t > 2 \), and bounded uniformly for \( t \geq 2 + \epsilon \) for any \( \epsilon > 0 \). This establishes that \( f_1, f_2 \) are finite for all \( \Re(z) > 2 \), and the sums defining them converge uniformly on vertical strips, and so on compacta. Finally, to show that \( f_1, f_2 \) are holomorphic in the half-plane \( \Re(z) > 2 \), we invoke the Weierstrass convergence theorem.

\[ \boxed{\text{Lemma 4.2.}} \quad \text{For any positive reals } x, y, w > 0, r \in \mathbb{N}, \text{ and } z \in \text{Dom}_3, \text{ define} \]

\[ G(z) := \sum_{n=1}^{\infty} \sum_{m=r}^{\infty} \frac{e^{wn}}{(x^2 n^2 + y^2 e^{wn})^{z/2}} \]

\[ \text{Then we have:} \]
1. $G$ is a holomorphic function on $\text{Dom}_3$;

2. $G$ has a meromorphic continuation to $\text{Dom}_2$ with a simple pole at $z = 3$;

3. This continuation can be written as

$$G(z) = \frac{\sqrt{\pi}}{2xyz^{-1}} \frac{\Gamma\left(\frac{z-1}{2}\right)}{\Gamma\left(\frac{z}{2}\right)} e^{-rw(z-3)/2} \frac{1}{1 - e^{-w(z-3)/2}} - \frac{1}{2yz} \frac{e^{-rw(z-2)/2}}{1 - e^{-w(z-2)/2}} + \text{err}(z)$$

where $\text{err}$ is a holomorphic function on $\text{Dom}_2$ that satisfies

$$|\text{err}(z)| \leq \frac{1}{2y} \frac{e^{-rw(\Re(z)-2)/2}}{1 - e^{-w(\Re(z)-2)/2}}.$$

**Proof.** Until further notice, we take $z$ real and positive. Later we will extend our results to complex $z$ as in Lemma 4.1. Inserting the Mellin transform of $f(t) = e^{-(x^2n^2 + y^2e^{wm})t}$ gives

$$G(z) = \sum_{n=1}^{\infty} \sum_{m=-r}^{\infty} e^{wm} \int_0^{\infty} t^{\frac{z-1}{2} - 1} e^{-tx^2n^2} e^{-ty^2e^{wm}} dt.$$

For $z$ real, all terms above are positive. Therefore we can apply Tonelli’s theorem to exchange the order of integration with summation. Having done this, we consider the sum $\sum_{n=1}^{\infty} e^{-tx^2n^2}$. The Poisson summation formula provides the identity

$$\sum_{n=1}^{\infty} e^{-tx^2n^2} = \frac{1}{2} \left( \sqrt{\frac{\pi}{tx^2}} \left( 1 + 2 \sum_{n=1}^{\infty} e^{-n^2/tx^2} \right) - 1 \right).$$

Substituting this identity into the expression for $G(z)$ we find

$$G(z) = \frac{1}{2} \sum_{m=-r}^{\infty} \frac{e^{wm}}{(y^2e^{wm})^{\frac{1}{2}}} \left( \sqrt{\frac{\pi}{x}} \frac{\Gamma\left(\frac{z-1}{2}\right)}{\Gamma\left(\frac{z}{2}\right)} (y^2e^{wm})^{\frac{1}{2}} - 1 \right)$$

$$+ \frac{\sqrt{\pi}}{x} \sum_{n=1}^{\infty} \sum_{m=-r}^{\infty} e^{wm} \int_0^{\infty} t^{\frac{z-1}{2} - 1} e^{-n^2/x} e^{-ty^2e^{wm}} dt.$$

To explore the convergence of the double sum we denote

$$g_n(s) := \int_0^{\infty} t^{\frac{z-1}{2} - 1} e^{-n^2/x} e^{-ts} dt.$$

Later we will set $s = y^2e^{wm} > 0$, so we consider only positive, real $s$, making $g_n(s)$ a positive real function. Using [OS, Section 26:14] to evaluate this Laplace transform gives

$$g_n(s) = 2 \left( \frac{n\pi}{x} \sqrt{s} \right)^{\frac{z-1}{2}} K_{\frac{z-1}{2}} \left( \frac{2n\pi \sqrt{s}}{x} \right)$$

where $u \mapsto K_{\nu}(u)$ is the modified Bessel function of the second kind. For $u > 0$ and real $\nu > 1/2$, $u^\nu K_{\nu}(u)$ is positive, as both $u^\nu$ and $K_{\nu}(u)$ are positive. Also, the derivative (referring again to [OS]) is given by

$$\frac{\partial}{\partial u} (u^\nu K_{\nu}(u)) = -u^\nu K_{\nu-1}(u) \leq 0 \quad \text{for all } u \geq 0.$$
Thus the function \( u \mapsto u^\nu K_\nu(u) \) is positive and monotonically decreasing for all \( u > 0 \). Hence for all \( \epsilon > 0 \) we have the bound
\[
\epsilon \sum_{n=1}^{\infty} (en)^\nu K_\nu(en) \leq \int_0^{\infty} u^\nu K_\nu(u) du. \tag{7}
\]
Evaluating the integral (using [OS, Chapter 51]) yields
\[
\sum_{n=1}^{\infty} (en)^\nu K_\nu(en) \leq \frac{1}{\epsilon} 2^\nu - 1 \Gamma(\frac{1}{2}) \Gamma(\nu + \frac{1}{2}).
\]
If we now set \( s = y^2 e^{rm} \), we obtain the bound
\[
s \sum_{n=1}^{\infty} \sum_{m=r}^{\infty} e^{rm} \Gamma(\frac{z}{2}) \int_0^{\infty} t^{\nu - 1} e^{-\frac{n^2 t^2}{4y^2}} e^{-ty^2 e^{rm}} dt \leq \sum_{n=1}^{\infty} \sum_{m=r}^{\infty} e^{rm} \frac{n\pi}{x y e^{rm/2}} \Gamma(\frac{z}{2}) K_{\frac{z}{2}} \left( \frac{2n\pi ye^{rm/2}}{x} \right).
\]
Now estimating the sum over \( n \) on the right using Equation (7) gives us
\[
2 \sum_{n=1}^{\infty} \left( \frac{n\pi}{x \sqrt{s}} \right)^{\frac{z}{2}} K_{\frac{z}{2}} \left( \frac{2n\pi \sqrt{s}}{x} \right) = 2 \left( \frac{1}{2s} \right)^{\frac{z}{2}} \sum_{n=1}^{\infty} \left( \frac{n\pi \sqrt{s}}{x} \right)^{\frac{z}{2}} K_{\frac{z}{2}} \left( \frac{2n\pi \sqrt{s}}{x} \right)
\]
\[
\leq 2 \left( \frac{1}{2s} \right)^{\frac{z}{2}} \frac{x}{2\pi \sqrt{s}} 2^{\frac{z}{2} - 1} \Gamma(\frac{z}{2}) \Gamma(\frac{1}{2})
\]
\[
= \frac{x \Gamma(\frac{1}{2}) \Gamma(\frac{z}{2})}{2\pi} \frac{1}{s^{z/2}} = \frac{x \Gamma(\frac{1}{2}) \Gamma(\frac{z}{2})}{2\pi y^2 e^{rm/2}}.
\]
Hence by summing the remaining geometric series in \( m \) we obtain the bound
\[
\sum_{n=1}^{\infty} \sum_{m=r}^{\infty} e^{rm} \Gamma(\frac{z}{2}) \int_0^{\infty} t^{\nu - 1} e^{-\frac{n^2 t^2}{4y^2}} e^{-ty^2 e^{rm}} dt \leq \frac{\Gamma(\frac{z}{2}) x \Gamma(\frac{1}{2})}{\Gamma(\frac{z}{2}) y^2 2\pi} \sum_{m=r}^{\infty} e^{rm/2} \leq \frac{x \Gamma(\frac{1}{2}) e^{-y^2/2}}{y^2 2\pi} \frac{e^{-r\rho(z-2)/2}}{1 - e^{-w(z-2)/2}}.
\]
Evaluating the remaining geometric series in \( G(z) \) as above, we arrive at
\[
G(z) = \frac{\sqrt{\pi}}{2xy^2 - 1} \frac{\Gamma(\frac{z+1}{2})}{\Gamma(\frac{z}{2})} \frac{e^{-r\rho(z-2)/2}}{1 - e^{-w(z-2)/2}} - \frac{1}{2y^2} \frac{e^{-r\rho(z-2)/2}}{1 - e^{-w(z-2)/2}} + err(z) \tag{8}
\]
where
\[
err(z) := \frac{\sqrt{\pi}}{x} \sum_{n=1}^{\infty} \sum_{m=r}^{\infty} e^{rm} \int_0^{\infty} t^{\nu - 1} e^{-\frac{n^2 t^2}{4x^2}} e^{-ty^2 e^{rm}} dt,
\]
\[
err(z) \leq \frac{1}{2y^2} \frac{e^{-r\rho(z-2)/2}}{1 - e^{-w(z-2)/2}}.
\]
Thus the sum defining the function $err$ converges for all $z > 2$, and this convergence is uniform on compact intervals. Now we observe that for $z \in \mathbb{C}$ we have $|G(z)| \leq G(|z|)$ and similarly $|err(z)| \leq err(|z|)$. Hence the sums defining $G$ converge uniformly on closed vertical strips in the half-plane $\text{Dom}_3$, and so on compacta. Similarly the sums and integral defining $err$ converge uniformly on compact subsets of the half-plane $\text{Dom}_2$.

Hence the Weierstrass convergence theorem implies that $err$ is holomorphic on the half-plane $\text{Dom}_2$ and that $G$ is holomorphic on $\text{Dom}_3$. Moreover the formula for $G$, Equation (8), provides a meromorphic continuation of $G$ to the half-plane $\text{Dom}_2$.

Lemma 4.3. The formula

$$f(z) := \sum_{n=0}^{\infty} \sum_{l=\frac{n}{2}}^{\infty} \frac{q^{n-2l}}{(1 + \lambda_{l,n}^2)^{z/2}}$$

defines a holomorphic function on $\text{Dom}_3$. Moreover $f$ has a meromorphic continuation to $\text{Dom}_2$, a simple pole at $z = 3$ with residue $4qQ^{-2}/\ln(q^{-1})$.

Proof. First we write

$$1 + \lambda_{l,n}^2 = 1 + \frac{n^2}{q^2} + q^n \left( \left[ l + \frac{1}{2} \right]^2 - \left[ \frac{n}{2} \right]^2 \right) = \frac{1}{4} n^2 + Q^2 q^{-1} q^{-2l} + C_{n,l}$$

where $C_{n,l}$ is uniformly bounded in $n, l$, and is given by

$$C_{n,l} = 1 + Q^2 q^n (q^{2l+1} - 2) - q^n \left[ \frac{n}{2} \right]^2, \quad |C_{n,l}| \leq 1 + 3Q^2.$$ 

Now we reparametrise the summation by letting $m = 2l - n$, yielding

$$f(z) = \sum_{n=0}^{\infty} \sum_{m=1}^{\infty} \frac{q^{-m}}{(\frac{1}{4} n^2 + Q^2 q^{-1} q^{-m} + C_{n,m})^{z/2}}$$

where we understand $C_{n,m} = C_{n,l=(n+m)/2}$. The function

$$z \mapsto \sum_{m=1}^{\infty} \frac{q^{-m}}{(Q^2 q^{-1} q^{-m} + C_{0,m})^{z/2}} = \sum_{m=1}^{\infty} \frac{q^{m(\frac{z}{2}-1)}}{(Q^2 q^{-1} + q^m C_{0,m})^{z/2}}$$

has summands with absolute value bounded by $M q^{m(\frac{z}{2}-1)}$, $M > 0$ constant, and so by the Weierstrass convergence theorem is holomorphic for $\text{Re}(z) > 2$. Hence for some holomorphic function $\text{holo}$ on $\text{Dom}_2$ we have

$$f(z) = \sum_{n,m=1}^{\infty} \frac{q^{-m}}{(\frac{1}{4} n^2 + Q^2 q^{-1} q^{-m} + C_{n,m})^{z/2}} + \text{holo}(z)$$

$$= \sum_{n,m=1}^{\infty} \frac{q^{-m}}{(\frac{1}{4} n^2 + Q^2 q^{-1} q^{-m})^{z/2}} \left( 1 + \frac{C_{n,m}}{\frac{1}{4} n^2 + Q^2 q^{-1} q^{-m}} \right)^{-z/2} + \text{holo}(z). \quad (9)$$
The strategy now is to perform a binomial expansion on
\[
\left( 1 + \frac{C_{n,m}}{n^2 + Q^2 q^{1-m}} \right)^{-z/2}
\]
ending up with a new sum of functions \(\sum_{n,m,k} D_{n,m,k} H(z + 2k)\) where \(H\) is as in Lemma 4.2. The binomial expansion requires the inequality
\[
\frac{C_{n,m}}{n^2 + Q^2 q^{1-m}} < 1
\]
which holds for sufficiently large \(m\). Recall that \(|C_{n,m}| \leq 1 + 3Q^2 =: C\) uniformly in \(n, m\), and so we may choose \(p \in \mathbb{N}\) such that
\[
q^p > qQ^{-2}C \implies \frac{|C_{n,m}|}{n^2 + Q^2 q^{1-m}} < 1 \quad \forall n \geq 1, \ m \geq p.
\]
Now, for any fixed \(p\), sums of the form
\[
\sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \left( \frac{q^{-m}}{n^2 + Q^2 q^{1-m}} \right)^{z/2} \left( 1 + \frac{C_{n,m}}{n^2 + Q^2 q^{1-m}} \right)^{-z/2} + \text{holo}(z).
\]
can immediately be seen to be holomorphic for \(\text{Re}(z) > 2\) as the sum can be bounded by a constant multiple of the Riemann zeta function. Hence for such a choice of \(p \in \mathbb{N}\) and for some holomorphic function \(\text{holo}\) on \(\text{Dom}_2\) we have
\[
f(z) = \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \left( \frac{q^{-m}}{n^2 + Q^2 q^{1-m}} \right)^{z/2} \left( 1 + \frac{C_{n,m}}{n^2 + Q^2 q^{1-m}} \right)^{-z/2} + \text{holo}(z).
\]
Now we perform the binomial expansion, separating the resulting infinite sum \(\sum_{k=0}^{\infty}\) into the \(k = 0\) term and \(\sum_{k=1}^{\infty}\). This gives
\[
f(z) = \sum_{n=1}^{\infty} \sum_{m=p}^{\infty} \left( \frac{q^{-m}}{n^2 + Q^2 q^{1-m}} \right)^{z/2} \left( 1 + \frac{C_{n,m}}{n^2 + Q^2 q^{1-m}} \right)^{-z/2} + \text{holo}(z)
\]
which is as in Lemma 4.2, with \(x = 1/2, y = q^{-1/2}Q, w = \ln(q^{-1})\) and \(r = p\). Our aim now is to show that \(f - G\) is a holomorphic function on \(\text{Dom}_2\). We need to show that the remaining summation converges to such a function. This remaining sum is bounded by
\[
\left| \sum_{k=1}^{\infty} \left( \frac{-\frac{1}{2}}{k^2} \right) \sum_{n=1}^{\infty} \sum_{m=p}^{\infty} \frac{q^{-m}(C_{n,m})^k}{n^2 + Q^2 q^{1-m} + 2k} \right|
\]
which implies
\[
\leq \sum_{k=1}^{\infty} \left| \left( \frac{-\frac{1}{2}}{k^2} \right) \right| C^k \sum_{n=1}^{\infty} \sum_{m=p}^{\infty} \frac{q^{-m}}{n^2 + Q^2 q^{1-m} + 2k}
\]
and
\[
= \sum_{k=1}^{\infty} \left| \left( \frac{-\frac{1}{2}}{k^2} \right) \right| C^k h(\text{Re}(z) + 2k).
\]
To estimate this sum of functions, we infer from Lemma 4.2 that there exists a positive function $M$ which is defined for $\text{Re}(z) > 3$ and such that

$$|h(z)| \leq M(z) \frac{e^{-\text{Re}(z)p/2}}{y \text{Re}(z)} = M(z)(q^{\frac{1}{2}(p+1)}Q^{-1})^{\text{Re}(z)}.$$  

Hence

$$\left| \sum_{k=1}^{\infty} \left( \begin{array}{c} -\frac{z}{2} \\ k \end{array} \right) \sum_{n=1}^{\infty} \sum_{m=p}^{\infty} \frac{q^{-m}(C_{n,m})^k}{n^2 + Q^2 q^{-m} - \frac{z^2}{4}} \right| \leq \sum_{k=1}^{\infty} \left| \begin{array}{c} -\frac{z}{2} \\ k \end{array} \right| C^k M(z+2k)(q^{\frac{1}{2}(p+1)}Q^{-1})^{\text{Re}(z)+2k}.$$  

Recall that $p$ was chosen such that $q^{-p} > qQ^{-2}C$. Also the function $z \mapsto M(z)$ is uniformly bounded for $\text{Re}(z) \geq 4$. Hence, for all $z$ with $\text{Re}(z) \geq 2$, the function $k \mapsto M(z+2k)$ is uniformly bounded in $k$, by $M$ say. It thus follows that the sum

$$\sum_{k=1}^{\infty} \left| \begin{array}{c} -\frac{z}{2} \\ k \end{array} \right| C^k M(z+2k)(q^{\frac{1}{2}(p+1)}Q^{-1})^{\text{Re}(z)+2k} \leq M \sum_{k=1}^{\infty} \left| \begin{array}{c} -\frac{z}{2} \\ k \end{array} \right| (q^{p+1}Q^{-2}C)^k$$

converges for $\text{Re}(z) > 2$, by comparing with the binomial expansion on the right hand side. The convergence is again uniform on compacta, so invoking Weierstrass’ convergence theorem we conclude that $f(z) - G(z)$ is holomorphic for $\text{Re}(z) > 2$. Hence there exists a function $\text{holo}$ which is defined and holomorphic for $\text{Re}(z) > 2$ such that

$$f(z) = \frac{\sqrt{\pi} \Gamma(z-1/2)}{(q^{-3/2}Q)^{z-1}} \frac{\Gamma(z-3/2)}{\Gamma(z-1/2)} - q^{(z-3/2)} + \text{holo}(z).$$

So we see $f(z)$ is holomorphic for $\text{Re}(z) > 3$, meromorphic for $\text{Re}(z) > 2$ and has a a simple pole at $z = 3$ with residue $4qQ^{-2}/\ln(q^{-1})$.

5. An analogue of a spectral triple

We now introduce an analogue of a spectral triple over $\mathcal{A}$. Let $\mathcal{H} := \mathcal{H}_h \oplus \mathcal{H}_h$ be the Hilbert space given by two copies of the GNS space $\mathcal{H}_h = L^2(A, h)$. We define a grading on $\mathcal{H}$ by $\Gamma = \left( \begin{array}{cc} 1 & 0 \\ 0 & -1 \end{array} \right)$. For any operator $\omega$ on $\mathcal{H}$ we abbreviate

$$\omega^+ := \frac{1+\Gamma}{2} \omega \frac{1+\Gamma}{2}, \quad \omega^- := \frac{1-\Gamma}{2} \omega \frac{1-\Gamma}{2}. \quad (10)$$

The algebra $\mathcal{A}$ is represented on $\mathcal{H}$ by

$$\alpha \mapsto \left( \begin{array}{cc} \pi_h(\alpha) & 0 \\ 0 & \pi_h(\alpha) \end{array} \right)$$

for $\alpha \in \mathcal{A}$. Here $\pi_h$ denotes the GNS representation by left multiplication on each copy of the space. In the sequel we will omit the symbol $\pi_h$. We now introduce
some unbounded operators and projections
\[
\hat{\Delta}_R = \begin{pmatrix} \Delta_R & 0 \\ 0 & \Delta_R \end{pmatrix}, \quad \hat{\Delta}_L = \begin{pmatrix} q^{-1} \Delta_L & 0 \\ 0 & q \Delta_L \end{pmatrix}, \quad \Psi_n = \begin{pmatrix} \Phi_{n+1} & 0 \\ 0 & \Phi_{n-1} \end{pmatrix}
\]
on \mathcal{A} \oplus \mathcal{A} \subset \mathcal{H} and use them to define (on the same domain)
\[
\mathcal{D} = \frac{1}{2} \sum_{n=-\infty}^{\infty} \Psi_n \begin{pmatrix} n & 0 \\ 0 & -n \end{pmatrix} + \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e \\ \partial_f & 0 \end{pmatrix}.
\]

Recall from Section 4 the numbers
\[
\lambda_{l,n} := \sqrt{\left( \frac{n}{2} \right)^2 + q^n \left( \left[ l + \frac{1}{2} \right]^2 - \left[ \frac{n}{2} \right]^2 \right)},
\]
where \( l \in \frac{1}{2} \mathbb{N}_0 \) and \( -(2l+1) \leq n \leq (2l+1) \). Also recall that
\[
I_l := \{-l, -l+1, \ldots, l-1, l\}.
\]

We will see in the following Proposition that the commutators \([\mathcal{D}, \alpha]\) of \( \mathcal{D} \) with algebra elements are not necessarily bounded, yet are unbounded in a very controlled manner. Even though \((\mathcal{A}, \mathcal{H}, \mathcal{D})\) thus fails to be a spectral triple, we will still be able to construct an analytic expression for a residue Hochschild cocycle from the commutators.

**Proposition 5.1.** The triple \((\mathcal{A}, \mathcal{H}, \mathcal{D})\) has the following properties:

1. The unbounded operator \( \mathcal{D} \) is essentially self-adjoint
2. The eigenvalues of \( \mathcal{D} \) are \( \{-(l + \frac{1}{2}), \pm \lambda_{l,2j-1} : l \in \frac{1}{2} \mathbb{N}_0, j \in I_l \\setminus \{-l\}\} \). The eigenvalue \(-(l + \frac{1}{2})\) has multiplicity 2 and \( \pm \lambda_{l,2j-1} \) has multiplicity \(2(2l+1)\).
3. The commutator \([\mathcal{D}, \alpha]\) is given by \( \hat{S}(\alpha) + \hat{T}(\alpha) \hat{\Delta}_L \), where the linear maps \( \hat{S}, \hat{T} : \mathcal{A} \to B(\mathcal{H}) \) are given by
\[
\hat{S}(\alpha) = \partial_{H}(\alpha) \Gamma, \quad \hat{T}(\alpha) = \begin{pmatrix} 0 & q^{-\frac{1}{2}} \partial_e(\sigma_L^{-\frac{1}{2}}(\alpha)) \\ q^{\frac{1}{2}} \partial_f(\sigma_L^{-\frac{1}{2}}(\alpha)) & 0 \end{pmatrix}.
\]

**Proof.** The set
\[
\left\{ \begin{pmatrix} 0 \\ l_{r,l} \end{pmatrix}, \begin{pmatrix} l_{r,s}^l \end{pmatrix}, \begin{pmatrix} C_{s,\pm}^l \end{pmatrix} : l \in \frac{1}{2} \mathbb{N}_0, r \in I_l, s \in I_l \setminus \{-l\} \right\},
\]
where \( C_{s,\pm}^l = \pm \lambda_{l,2s-1} - (s - \frac{1}{2}) \)
\[
\frac{1}{q^{-\frac{1}{2}}} \sqrt{\left[ l + \frac{1}{2} \right]^2 - \left[ s - \frac{1}{2} \right]^2}
\]
is an orthogonal basis for \( \mathcal{H} \) comprised of eigenvectors of \( \mathcal{D} \). The corresponding eigenvalues are \(-l + \frac{1}{2}), -(l + \frac{1}{2})\) and \( \pm \lambda_{l,2s-1} \) respectively. This spectral representation establishes that \( \mathcal{D} \) is essentially self-adjoint.
Next, the commutator of $\mathcal{D}$ with a homogeneous algebra element $\alpha = \Phi_p(\alpha)$, for some $p \in \mathbb{Z}$, is computed directly. It is sufficient to consider just this case, because $\mathcal{A}$ consists of finite linear combinations of homogeneous elements (the generators are homogeneous). For such an element $\alpha$ we have

$$
[\mathcal{D}, \alpha] = \frac{1}{2} \sum_{n=-\infty}^{\infty} \Psi_n \alpha \begin{pmatrix} n & 0 \\ 0 & -n \end{pmatrix} + \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e \\ \partial_f & 0 \end{pmatrix} \alpha \\
- \frac{1}{2} \sum_{n=-\infty}^{\infty} \alpha \Psi_n \begin{pmatrix} n & 0 \\ 0 & -n \end{pmatrix} - \alpha \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e \\ \partial_f & 0 \end{pmatrix}.
$$

It follows from the definition of the projections $\Phi_n$, now regarded as a linear operator on $\mathcal{H}_h$, that $\alpha \Phi_n = \Phi_{n+p} \alpha$ for any $n \in \mathbb{Z}$. Using this, together with the definition of the derivations $\partial_e$ and $\partial_f$ in Equation 1, the commutator simplifies to

$$
[\mathcal{D}, \alpha] = \frac{1}{2} \alpha \sum_{n=-\infty}^{\infty} \Psi_n \left( \begin{pmatrix} n + p & 0 \\ 0 & -n - p \end{pmatrix} - \begin{pmatrix} n & 0 \\ 0 & -n \end{pmatrix} \right) \\
+ \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & (\partial_e(\alpha) \Delta_L^{\frac{1}{2}} + \sigma_L^{\frac{1}{2}}(\alpha) \partial_e) \\ (\partial_f(\alpha) \Delta_L^{\frac{1}{2}} + \sigma_L^{\frac{1}{2}}(\alpha) \partial_f) & 0 \end{pmatrix} \\
- \alpha \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e \\ \partial_f & 0 \end{pmatrix}.
$$

Since $\sigma_L^{\frac{1}{2}}(\alpha) = \Delta_L^{\frac{1}{2}} \alpha \Delta_L^{\frac{1}{2}}$ as operators on $\mathcal{A} \oplus \mathcal{A} \subset \mathcal{H}$, the last expression for the commutator simplifies to

$$
\hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \sigma_L^{\frac{1}{2}}(\alpha) \partial_e \\ \sigma_L^{\frac{1}{2}}(\alpha) \partial_f & 0 \end{pmatrix} = \alpha \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e \\ \partial_f & 0 \end{pmatrix}.
$$

and hence

$$
[\mathcal{D}, \alpha] = \frac{p}{2} \alpha \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} + \hat{\Delta}_L^{\frac{1}{2}} \begin{pmatrix} 0 & \partial_e(\alpha) \Delta_L^{\frac{1}{2}} \\ (\partial_f(\alpha) \Delta_L^{\frac{1}{2}}) & 0 \end{pmatrix} \\
= \partial_H(\alpha) \Gamma + \begin{pmatrix} 0 & q^{-\frac{1}{2}} \partial_e(\sigma_L^{-\frac{1}{2}}(\alpha)) \\ q^{\frac{1}{2}} \partial_f(\sigma_L^{-\frac{1}{2}}(\alpha)) & 0 \end{pmatrix} \hat{\Delta}_L.
$$

6. The residue Hochschild cocycle

The main step in the definition of the residue cocycle is the construction of a functional that plays the role of an integral. In the situations considered in the literature thus far, [C, BeF, GVF, CNNR, CPRS1, KW], functionals of the form

$$
T \mapsto \tau(T(1 + \mathcal{D}^2)^{-z/2})
$$
Lemma 6.1. For each preserving the subspace $A \oplus A \subset H$ continues to make sense for possibly unbounded positive operators defined on and where $\hat{\Delta}$ von Neumann algebra is just were used, where $z \in \mathbb{C}$ and $\tau$ is a faithful normal semifinite trace, or at worst a weight, on a von Neumann algebra containing the algebra of interest. Often, the von Neumann algebra is just $\mathcal{B}(H)$, and the functional $\tau$ is the operator trace.

In this example, we need to apply our functional to products of commutators $[D, \alpha] \sim \hat{\Delta}_L$ with $\alpha \in \mathcal{A}$, so it has to be defined on an algebra of unbounded operators. We will deal with this using a cutoff that is defined by the projections

$$L_m := \hat{L}_m \oplus \check{L}_m, \quad \check{L}_m(t_{r,s}) := \begin{cases} t_{r,s}^l & l \leq m \\ 0 & \text{otherwise} \end{cases}$$

and

$$P_1 = \sum_{n=0}^{\infty} \Psi_n, \quad P_2 \left( \begin{array}{c} t_{r,s}^l \\ 0 \end{array} \right) = (1 - \delta_{s,-l}) \left( \begin{array}{c} t_{r,s}^l \\ 0 \end{array} \right), \quad P_2 \left( \begin{array}{c} 0 \\ t_{r,s}^l \end{array} \right) = (1 - \delta_{s,l}) \left( \begin{array}{c} 0 \\ t_{r,s}^l \end{array} \right).$$

Observe $P_2$ is the projection onto $\left( \ker \left( \begin{array}{cc} 0 & \partial_x \\ \partial_x & 0 \end{array} \right) \right) \perp$, and that the projections $L_m$ converge strongly to the identity in $\mathcal{B}(H)$.

For $w \in \mathbb{R}^+$ we now define a functional $\Upsilon_w$ on positive operators $\rho \in \mathcal{B}(H)$ in the following way:

$$\Upsilon_w(\rho) := \sup_{m \in \mathbb{N}} \operatorname{Tr} \left( P_1 P_2 L_m (1 + \mathcal{D}^2)^{-w/4} \hat{\Delta}^{-\frac{1}{2}} \rho \hat{\Delta}^{-\frac{1}{2}} (1 + \mathcal{D}^2)^{-w/4} P_1 P_2 L_m \right),$$

where $\hat{\Delta}_F = \hat{\Delta}_F^L$ and $\operatorname{Tr}$ is the operator trace on $\mathcal{B}(H)$. This expression continues to make sense for possibly unbounded positive operators defined on and preserving the subspace $\mathcal{A} \oplus \mathcal{A} \subset H$.

**Lemma 6.1.** For each $w \in \mathbb{R}^+$ the functional $\Upsilon_w$ is positive and normal on $\mathcal{B}(H)_+$. It is faithful and semifinite on $P_1 P_2 \mathcal{B}(H)_+ P_1 P_2$.

**Proof.** We will compute the operator trace using the Peter-Weyl basis

$$\left\{ \left( \begin{array}{c} t_{r,s}^l \\ 0 \end{array} \right), \left( \begin{array}{c} 0 \\ t_{r,s}^l \end{array} \right) \right\}$$

for $\mathcal{H}$. The operators $(1 + \mathcal{D}^2)$, $\hat{\Delta}_F$, $P_1$, $P_2$ and $L_m$ are all positive and diagonal in this basis. By using the definition of the operator trace, the value of the operators $\hat{\Delta}^{-1}_F$ and $(1 + \mathcal{D}^2)^{-w/4}$ on this basis, and the symmetry property for self-adjoint operators, we compute $\Upsilon_w(\rho)$ for $\rho \in \mathcal{B}(H)_+$ (or even $\rho \geq 0$ and affiliated to $\mathcal{B}(H)$) by

$$\operatorname{Tr} \left( P_1 P_2 L_m (1 + \mathcal{D}^2)^{-w/4} \hat{\Delta}^{-\frac{1}{2}} \rho \hat{\Delta}^{-\frac{1}{2}} (1 + \mathcal{D}^2)^{-w/4} P_1 P_2 L_m \right) =$$

$$= \sum_{2l=0}^{\infty} \sum_{r=-l}^{l} \sum_{s=-l}^{l} q^{-2r-(2s-1)} \frac{\langle P_1^+ P_2^+ L_m t_{r,s}^l, \rho^+ P_1^+ P_2^+ L_m t_{r,s}^l \rangle}{\langle t_{r,s}^l, t_{r,s}^l \rangle}$$

$$+ \sum_{2l=0}^{\infty} \sum_{r=-l}^{l} \sum_{s=-l}^{l} q^{-2r-(2s+1)} \frac{\langle P_1^+ P_2^+ L_m t_{r,s}^l, \rho^- P_1^+ P_2^+ L_m t_{r,s}^l \rangle}{\langle t_{r,s}^l, t_{r,s}^l \rangle},$$

where $q^{2r-(2s-1)} = q^{2s-(2r+1)}$, and $\langle \cdot, \cdot \rangle$ is the inner product on $\mathcal{H}$. The summations are over all $2l$ and $r, s$ with $-l \leq r, s \leq l$, where $l = \sqrt{(r^2 + s^2)}$. The terms involving $q$ are non-negative, and the terms involving $\langle \cdot, \cdot \rangle$ are positive definite. Therefore, the sum is non-negative and converges for all $\rho \in \mathcal{B}(H)_+$.

This completes the proof of Lemma 6.1.
where \( \rho^+ \) and \( \rho^- \) are as in Equation (10). Now,

\[
P_1^+ P_2^+ L_m t^l_{r,s} = \begin{cases} t^l_{r,s} & \frac{1}{2} \leq s \leq l, \frac{1}{2} \leq l \leq m \\ 0 & \text{otherwise} \end{cases}
\]

\[
P_1^- P_2^- L_m t^l_{r,s} = \begin{cases} t^l_{r,s} & -\frac{1}{2} \leq s \leq l - 1, \frac{1}{2} \leq l \leq m \\ 0 & \text{otherwise.} \end{cases}
\]

So if we set \( n = 2s \pm 1 \) and recall the sets

\[
\mathcal{J}_l := \begin{cases} \{0, 2, \ldots, 2l - 1\} & l \in \mathbb{N}_0 + \frac{1}{2} \\ \{1, 3, \ldots, 2l - 1\} & l \in \mathbb{N} \end{cases}
\]

we may express the trace as

\[
\text{Tr} \left( P_1 P_2 L_m (1 + \mathcal{D}^2)^{-w/4} \hat{\Delta}_F^{-\frac{1}{2}} \rho \hat{\Delta}_F^{-\frac{1}{2}} (1 + \mathcal{D}^2)^{-w/4} P_1 P_2 L_m \right) = \sum_{2l=1}^{2k} \sum_{r=-l}^{l} \sum_{n \in J_l} q^{-2r-n} \frac{(1 + \lambda^2_{l,n})^{w/2}}{2l} \left( \frac{\left\langle t^l_{r,s + \frac{1}{2}}, \rho t^l_{r,s + \frac{1}{2}} \right\rangle}{\left\langle t^l_{r,s + \frac{1}{2}}, t^l_{r,s + \frac{1}{2}} \right\rangle} + \frac{\left\langle t^l_{r,s - \frac{1}{2}}, \rho t^l_{r,s - \frac{1}{2}} \right\rangle}{\left\langle t^l_{r,s - \frac{1}{2}}, t^l_{r,s - \frac{1}{2}} \right\rangle} \right). \tag{12}
\]

This shows that \( \Upsilon_w \) is a supremum of a sum of positive vector states and so automatically positive and normal. To see that it is faithful on \( P_1 P_2 \mathcal{B}(\mathcal{H}) P_1 P_2 \) we observe that the operator trace is faithful and that \( P_1 P_2 \hat{\Delta}_F^{-1/2} (1 + \mathcal{D}^2)^{-w/4} \) is injective on \( P_1 P_2 \mathcal{H} \). The semifiniteness comes from the fact that finite rank operators are in the domain of \( \Upsilon_w \). \( \blacksquare \)

We extend \( \Upsilon_w \) to an unbounded positive normal linear functional on \( \mathcal{B}(\mathcal{H}) \) as usual. In fact, we extend it also to unbounded operators \( \rho \) defined on and preserving \( \mathcal{A} \oplus \mathcal{A} \) by decomposing \( L_k \omega L_k \) for each \( k \) into a linear combination of positive bounded operators.

If for an operator \( \rho \) (not necessarily bounded) the function \( w \mapsto \Upsilon_w(\rho) \) has a meromorphic continuation to \( \text{Dom}_{3-\delta} \) for some \( \delta > 0 \), then we define

\[
\tau(\rho) := \text{Res}_{z=3} \Upsilon_z(\rho). \tag{13}
\]

**Lemma 6.2.** The functional \( \tau \) is defined on the positive operator \( c^* c \), and \( \tau(c^* c) = 0 \). Indeed, for all \( m \geq 1 \),

\[
\tau \left( \begin{pmatrix} (c^* c)^m & 0 \\ 0 & 0 \end{pmatrix} \right) = \tau \left( \begin{pmatrix} 0 & (c^* c)^m \\ 0 & 0 \end{pmatrix} \right) = 0.
\]

**Proof.** The action of the operator \( c = c^+ + c^- \) may be described using the Clebsch-Gordan coefficients (see for example [DLSSV], [KS]): we have

\[
c^+ t^l_{r,s} = c^+_{r,s} t^{l+\frac{1}{2}}_{r+\frac{1}{2}, s-\frac{1}{2}} \quad \quad c^- t^l_{r,s} = c^-_{r,s} t^{l-\frac{1}{2}}_{r+\frac{1}{2}, s-\frac{1}{2}},
\]

where \( c^+ \) and \( c^- \) are as in Equation (10). Now,
appearing in the formula for $\Upsilon_z$ 

The definition of $C$ means that the limits as $p \to \infty$ of the two sums above exist for $z > 2$. Hence 

$$z \mapsto \Upsilon_z \left( \begin{pmatrix} c^*c & 0 \\ 0 & 0 \end{pmatrix} \right), \quad z \mapsto \Upsilon_z \left( \begin{pmatrix} 0 & 0 \\ 0 & c^*c \end{pmatrix} \right)$$
are well-defined functions for $z > 2$. Indeed the arguments of Lemma 4.1, together with the Weierstrass convergence theorem, show that these functions extend to holomorphic functions on $\text{Dom}_2$. In particular, these functions are holomorphic at $z = 3$ and hence
\[
\tau\left(\begin{pmatrix} c^*c & 0 \\ 0 & 0 \end{pmatrix}\right) = \tau\left(\begin{pmatrix} 0 & 0 \\ 0 & c^*c \end{pmatrix}\right) = 0.
\]

By linearity it follows that $\tau(c^*c) = 0$ also. Using the normality of $c$, for any operator $X$ we have the operator inequality
\[
X^*(c^*c)^m X \leq \|c^*c\|^{m-1} X^* c^*c X,
\]
and so for $z > 2$ real, we have $\Upsilon_z((c^*c)^m) \leq \|c\|^{2m-2} \Upsilon_z(c^*c)$. Thus for $z > 2$, the sum defining $\Upsilon_z((c^*c)^m)$ converges. Once more invoking the Weierstrass convergence theorem shows that $z \mapsto \Upsilon_z((c^*c)^m)$ extends to a holomorphic function for $\Re(z) > 2$. Similar estimates now show that
\[
\tau\left(\begin{pmatrix} (c^*c)^m & 0 \\ 0 & 0 \end{pmatrix}\right) = \tau\left(\begin{pmatrix} 0 & 0 \\ 0 & (c^*c)^m \end{pmatrix}\right) = 0.
\]

**Theorem 6.3.** Let $\alpha \in \mathcal{A}$ and $X, Y$ be any closed linear operators on $\mathcal{H}_h$ which are defined on and preserve $\mathcal{A}$. Then we have the following well-defined evaluations of $\tau$:

1. $\tau\left(\begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix}\right) = \tau\left(\begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix}\right) = 0$
2. $\tau(\alpha \Gamma) = 0$
3. $\tau\left(\hat{\Delta}_L^2 \begin{pmatrix} \alpha & 0 \\ 0 & 0 \end{pmatrix}\right) = \tau\left(\hat{\Delta}_L^2 \begin{pmatrix} 0 & 0 \\ 0 & \alpha \end{pmatrix}\right) = R \int_{[1]} \alpha$

where $\int_{[1]} : \mathcal{A} \to \mathbb{C}$ is the functional defined in Lemma 3.2 and
\[
R := 4(q^{-1} - q)/\ln(q^{-1}).
\]

**Proof.** Throughout this proof we assume without loss of generality that any element of $\mathcal{A}$ is homogeneous with respect to both the left and right actions (that is $\sigma_L(\alpha) = q^p \alpha$, $\sigma_R(\alpha) = q^{p'} \alpha$ for some $p, p'$). This is because finite linear combinations of homogeneous elements span $\mathcal{A}$ (cf. Theorem 2.2).

Indeed, if $\alpha \in \mathcal{A}$ is homogeneous of a non-zero degree for either the left or right action, then $\langle t_{t,s}, \alpha t_{t,s} \rangle = 0$ and so for any linear operator $C$ that is diagonal in the Peter-Weyl basis, $T_w(C\alpha) = 0$ for all $w \in \mathbb{R}_+$. Hence, we need only consider those elements of $\mathcal{A}$ that are homogeneous of degree zero for the left and right actions. A convenient spanning set for these algebra elements is $\{1_{\mathcal{A}}, (c^*c)^m : m \in \mathbb{N}\}$. 

1. By definition of $\Upsilon$, we have

$$
\Upsilon_w \left( \begin{pmatrix} 0 & X \\ 0 & 0 \end{pmatrix} \right) = \Upsilon_w \left( \begin{pmatrix} 0 & 0 \\ Y & 0 \end{pmatrix} \right) = 0
$$

for all $w > 0$.

2.Lemma 6.2 has established that for all $m \geq 1$,

$$
\tau \left( \begin{pmatrix} (c^*c)^m & 0 \\ 0 & 0 \end{pmatrix} \right) = \tau \left( \begin{pmatrix} 0 & 0 \\ (c^*c)^m \end{pmatrix} \right) = 0.
$$

By linearity we can extend this to conclude that $\tau((c^*c)^m \Gamma) = 0$. Finally, for $z$ large and real we compute $\Upsilon_z(\Gamma)$ using the proof of Lemma 6.1. Now

$$
\text{Tr} \left( P_1 P_2 L_p (1 + D^2)^{-z/4} \hat{\Delta}^{-\frac{1}{2}}_F \hat{\Delta}^{-\frac{1}{2}}_L (1 + D^2)^{-z/4} P_1 P_2 L_p \right)
$$

$$
= \sum_{2l=1}^{2p} \sum_{r=-l}^{l} \sum_{n \in J_l} \frac{q^{-2r-n}}{(1 + \lambda_{l,n}^2)^{z/2}} - \sum_{2l=1}^{2k} \sum_{r=-l}^{l} \sum_{n \in J_l} \frac{q^{-2r-n}}{(1 + \lambda_{l,n}^2)^{z/2}},
$$

and for each $p$ the summands above are finite and hence subtract to give zero. Hence $\Upsilon_z(\Gamma) = 0$ for all $z$ and so $\tau(\Gamma) = 0$.

3. For $z$ large and real, the evaluation of $\Upsilon_z$ as sums of positive real numbers (as in the proof of Lemma 6.1) implies the numerical inequality

$$
\Upsilon_z(\hat{\Delta}^2_L((c^*c)^m)) \leq \Upsilon_z((c^*c)^m).
$$

This is because the introduction of $\hat{\Delta}^2_L$ multiplies each summand by $q^{2n} \leq 1$ (cf. Equation (12)). Lemma 6.2 demonstrates that $\Upsilon_z((c^*c)^m)$ extends to a function that is holomorphic in a neighbourhood of $z = 3$, and together with the Weierstrass convergence theorem result follows.

Finally we analyse $\Upsilon_z \left( \hat{\Delta}^2_L \left( \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \right) \right)$ and $\Upsilon_z \left( \hat{\Delta}^2_L \left( \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right) \right)$. Again using the proof of Lemma 6.1 we find

$$
\text{Tr} \left( P_1 P_2 L_p (1 + D^2)^{-z/4} \hat{\Delta}^{-\frac{1}{2}}_F \hat{\Delta}^{-\frac{1}{2}}_L (1 + D^2)^{-z/4} P_1 P_2 L_p \right)
$$

$$
= \text{Tr} \left( P_1 P_2 L_p (1 + D^2)^{-z/4} \hat{\Delta}^{-\frac{1}{2}}_F \hat{\Delta}^{-\frac{1}{2}}_L \left( \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \right) \hat{\Delta}^{-\frac{1}{2}}_F (1 + D^2)^{-z/4} P_1 P_2 L_p \right)
$$

$$
= \sum_{2l=1}^{2p} \sum_{r=-l}^{l} \sum_{n \in J_l} \frac{q^{-2r+n}}{(1 + \lambda_{l,n}^2)^{z/2}} - Qq \sum_{2l=1}^{2k} \sum_{r=-l}^{l} \sum_{n \in J_l} \frac{q^{n+2l}}{(1 + \lambda_{l,n}^2)^{z/2}}.
$$

For $z$ real, the sum $\sum_{2l=1}^{2k} \sum_{n \in J_l} q^{n+2l}/(1 + \lambda_{l,n}^2)^{z/2}$ is bounded above by $f_2(z)$ from Lemma 4.1 for all $p$. By the Weierstrass convergence theorem we conclude that as $p \to \infty$, this sum converges to a function with a holomorphic
extension about $z = 3$. Next, when considering the sum $\sum_{2l=1}^{2k} \sum_{n \in J_l} q^{n-2l}/(1 + \lambda_{l,n}^2)^{z/2}$, observe by rearranging the order of summation

$$\sum_{2l=1}^{2k} \sum_{n \in J_l} \Rightarrow \sum_{n=0}^{2k} \sum_{l=(n+1)/2}^k,$$

that Lemma 4.3 proves that the sum has a limit as $k \to \infty$ and the corresponding function of $z$ extends to a meromorphic function with a simple pole at $z = 3$. The residue at $z = 3$ is $4qQ^{-2}/\ln(q^{-1})$ and from the definition of $\tau$ we conclude that for $R = 4(q^{-1} - q)/\ln(q^{-1})$,

$$\tau \left( \hat{\Delta}_L^2 \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \right) = \tau \left( \hat{\Delta}_L^2 \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right) = R.$$

Finally, we compare the definition of $R \int_{[1]}$ in Lemma 3.2 to the evaluation of $\tau$ on $A$ derived here and observe that they agree on $A$.

**Lemma 6.4.** Given any matrix $M \in M_2(A)$ and any $\alpha \in A$ we have

$$\tau(M\hat{\Delta}_L^2 \alpha) = \tau(\vartheta^{-1}(\alpha)M\hat{\Delta}_L^2).$$

**Proof.** From Lemma 3.2, the linear functional $\int_{[1]}$ is a $\sigma_L^2 \circ \vartheta^{-1}$-twisted trace. That is, given any $\alpha, \beta \in A$

$$\int_{[1]} \alpha \beta = \int_{[1]} \sigma_L^2(\vartheta^{-1}(\beta))\alpha.$$

Now we separate the matrix $M = M_d + M_o$ into diagonal and off-diagonal matrices respectively. Then by Theorem 6.3, $\tau(M_d\hat{\Delta}_L^2 \alpha)$ and $\tau(M_o\hat{\Delta}_L^2 \alpha)$ are both well-defined, so by linearity

$$\tau(M\hat{\Delta}_L^2 \alpha) = \tau(M_d\hat{\Delta}_L^2 \alpha) + \tau(M_o\hat{\Delta}_L^2 \alpha) = \tau(M_d\hat{\Delta}_L^2 \alpha) + 0.$$

Since $M_d$ is diagonal, we may write

$$M_d\hat{\Delta}_L^2 = \hat{\Delta}_L^2 \sigma_L^2(M_d)$$

where $\sigma_L$ acts componentwise on the matrix. Using the value of $\tau(\hat{\Delta}_L^2 \sigma_L^2(M_d)\alpha)$ from Theorem 6.3, we have

$$\tau(M\hat{\Delta}_L^2 \alpha) = \tau(\hat{\Delta}_L^2 \sigma_L^2(M_d)\alpha) = R \int_{[1]} \sigma_L^2(M_d^+)\alpha + R \int_{[1]} \sigma_L^2(M_d^-)\alpha$$

$$= R \int_{[1]} \sigma_L^2(\vartheta^{-1}(\alpha))\sigma_L^2(M_d^+) + R \int_{[1]} \sigma_L^2(\vartheta^{-1}(\alpha))\sigma_L^2(M_d^-),$$

by the twisted trace property of $\int_{[1]}$. Recombining these two terms yields

$$\tau(\hat{\Delta}_L^2 \sigma_L^2(M_d)\alpha) = \tau(\hat{\Delta}_L^2 \sigma_L^2(\vartheta^{-1}(\alpha))\sigma_L^2(M_d)) = \tau(\vartheta^{-1}(\alpha)\hat{\Delta}_L^2 \sigma_L^2(M_d)) = \tau(\vartheta^{-1}(\alpha)M_d\hat{\Delta}_L^2).$$

Now, $\tau(\vartheta^{-1}(\alpha)M_d\hat{\Delta}_L^2)$ is well defined and has value zero, so we can write

$$\tau(M\hat{\Delta}_L^2 \alpha) = \tau(\vartheta^{-1}(\alpha)M_d\hat{\Delta}_L^2) + \tau(\vartheta^{-1}(\alpha)M_o\hat{\Delta}_L^2) = \tau(\vartheta^{-1}(\alpha)M\hat{\Delta}_L^2).$$

$\blacksquare$
Theorem 6.5. Given any $a_0, \ldots, a_3 \in \mathcal{A}$, the map

$$\phi_{\text{res}} : a_0, \ldots, a_3 \mapsto \tau(a_0[D, a_1][D, a_2][D, a_3])$$

is a $\vartheta^{-1}$-twisted Hochschild 3-cocycle, whose cohomology class is non-trivial. The cocycle $\phi_{\text{res}}$ has non-zero pairing with the $\vartheta^{-1}$-twisted 3-cycle $\text{dvol}$ defined in (2), giving

$$\langle \phi_{\text{res}}, \text{dvol} \rangle = 3R(q^{-1} + q) = 4! q^{-1} + q \frac{q^{-1} - q}{\ln(q^{-1})}.$$ 

The cocycle may be written as

$$\phi_{\text{res}} = q^2 R(\varphi + \varphi_{213} + \varphi_{231}) + R(\varphi_{132} + \varphi_{312} + \varphi_{321})$$

where $\varphi$ and $\varphi_{ijk}$ are the cocycles described in Lemma 3.2 and Corollary 3.4.

Proof. First consider $\pi_D(a_0, a_1, a_2, a_3) = a_0[D, a_1][D, a_2][D, a_3]$ as an unbounded operator on $\mathcal{A} \oplus \mathcal{A} \subset \mathcal{H}$. Using the equality $[D, a] = S(\alpha) + T(\alpha)\hat{\Delta}_L$, we see that $\pi_D(a_0, a_1, a_2, a_3)$ can be expanded into 8 terms. Recall that by Theorem 6.3 the functional $\tau$ vanishes on off-diagonal operators. Four of the eight terms in the expansion of $\pi_D(a_0, a_1, a_2, a_3)$ are off-diagonal, since for all $\alpha \in \mathcal{A}$, $S(\alpha)$ is diagonal and $T(\alpha)$ is off-diagonal. Thus

$$\tau \left( a_0 \left( \hat{T}(a_1)\hat{\Delta}_L \hat{S}(a_2)\hat{S}(a_3) + \hat{S}(a_1)\hat{T}(a_2)\hat{\Delta}_L \hat{S}(a_3) \\
+ \hat{S}(a_1)\hat{S}(a_2)\hat{T}(a_3)\hat{\Delta}_L + \hat{T}(a_1)\hat{\Delta}_L \hat{T}(a_2)\hat{\Delta}_L \hat{T}(a_3)\hat{\Delta}_L \right) \right) = 0.$$

Therefore, $\phi_{\text{res}}(a_0, a_1, a_2, a_3)$ reduces to

$$\phi_{\text{res}}(a_0, a_1, a_2, a_3) = \tau \left( a_0 \left( \hat{S}(a_1)\hat{S}(a_2)\hat{S}(a_3) + \hat{S}(a_1)\hat{T}(a_2)\hat{\Delta}_L \hat{T}(a_3)\hat{\Delta}_L \\
+ \hat{T}(a_1)\hat{\Delta}_L \hat{S}(a_2)\hat{T}(a_3)\hat{\Delta}_L + \hat{T}(a_1)\hat{\Delta}_L \hat{T}(a_2)\hat{\Delta}_L \hat{S}(a_3) \right) \right). \quad (14)$$

From Proposition 5.1 it follows that

$$a_0\hat{S}(a_1)\hat{S}(a_2)\hat{S}(a_3) = a_0 \partial_H(a_1) \partial_H(a_2) \partial_H(a_3) \Gamma$$

and recall that from Theorem 6.3 we know $\tau(\alpha \Gamma) = 0$ for all $\alpha \in \mathcal{A}$. Since $a_0 \partial_H(a_1) \partial_H(a_2) \partial_H(a_3) \in \mathcal{A}$ we have

$$\tau(a_0 \hat{S}(a_1)\hat{S}(a_2)\hat{S}(a_3)) = 0.$$

We now move all the $\hat{\Delta}_L$’s to the right in the remaining terms in Equation (14). For $\alpha \in \mathcal{A}$, we use $\hat{\Delta}_L \hat{S}(\alpha) = \hat{S}(\sigma_L^{-1}(\alpha))\hat{\Delta}_L$, and

$$\hat{\Delta}_L \hat{T}(\alpha) = \left( \begin{array}{cc} 0 & q^{-1}\Delta_L q^{-\frac{1}{2}} \partial_e(\sigma_L^{-\frac{1}{2}}(\alpha)) \\ q\Delta_L q^{\frac{1}{2}} \partial_f(\sigma_L^{-\frac{1}{2}}(\alpha)) & 0 \end{array} \right) \hat{\Delta}_L$$

$$= \left( \begin{array}{cc} 0 & q^{-2}\Delta_L^{-1}(\partial_e(\sigma_L^{-\frac{1}{2}}(\alpha))) \\ q^{2} q^{\frac{1}{2}} \sigma_L^{-1}(\partial_f(\sigma_L^{-\frac{1}{2}}(\alpha))) & 0 \end{array} \right) \hat{\Delta}_L$$

$$= \left( \begin{array}{cc} 0 & q^{-\frac{1}{2}} \partial_e(\sigma_L^{-\frac{1}{2}}(\alpha)) \\ q^{\frac{1}{2}} \partial_f(\sigma_L^{-\frac{1}{2}}(\alpha)) & 0 \end{array} \right) \hat{\Delta}_L$$

$$= \hat{T}(\sigma_L^{-1}(\alpha)) \hat{\Delta}_L.$$
This yields

\[ \phi_{\text{res}}(a_0, a_1, a_2, a_3) = \tau \left( a_0 \left( \tilde{S}(a_1) \tilde{T}(a_2) \tilde{T}(\sigma_L^{-1}(a_3)) + \tilde{T}(a_1) \tilde{S}(\sigma_L^{-1}(a_2)) \tilde{T}(\sigma_L^{-1}(a_3)) + \tilde{T}(a_1) \tilde{T}(\sigma_L^{-1}(a_2)) \tilde{S}(\sigma_L^{-2}(a_3)) \right) \right). \]

In this form Theorem 6.3 tells us that \( \phi_{\text{res}} \) is a well-defined, multilinear functional on \( \mathcal{A}^{\otimes 4} \). In order to demonstrate that this cochain is indeed a twisted Hochschild cocycle, it remains only to show that the boundary operator maps the cochain to zero. This result follows from the Leibniz property of the commutators together with Lemma 6.4. Explicitly,

\[
(b_3^{\varrho^{-1}} \phi_{\text{res}})(a_0, \ldots, a_4) = \tau(a_0 a_1 [\mathcal{D}, a_2] [\mathcal{D}, a_3][\mathcal{D}, a_4]) - \tau(a_0 [\mathcal{D}, a_1 a_2][\mathcal{D}, a_3][\mathcal{D}, a_4]) + \tau(a_0 [\mathcal{D}, a_1][\mathcal{D}, a_2 a_3][\mathcal{D}, a_4]) - \tau(a_0 [\mathcal{D}, a_1][\mathcal{D}, a_2][\mathcal{D}, a_3 a_4]) + \tau(\varrho^{-1}(a_4) a_0 [\mathcal{D}, a_1][\mathcal{D}, a_2][\mathcal{D}, a_3]) = -\tau(a_0 [\mathcal{D}, a_1][\mathcal{D}, a_2][\mathcal{D}, a_3]a_4) + \tau(\varrho^{-1}(a_4) a_0 [\mathcal{D}, a_1][\mathcal{D}, a_2][\mathcal{D}, a_3]) = 0,
\]

where the last equality follows from Lemma 6.4.

In order to identify \( \phi_{\text{res}} \), we use Proposition 5.1 to write, for \( a_0, \ldots, a_3 \in \mathcal{A} \),

\[
a_0 \left( \tilde{S}(a_1) \tilde{T}(a_2) \tilde{T}(\sigma_L^{-1}(a_3)) + \tilde{T}(a_1) \tilde{S}(\sigma_L^{-1}(a_2)) \tilde{T}(\sigma_L^{-1}(a_3)) + \tilde{T}(a_1) \tilde{T}(\sigma_L^{-1}(a_2)) \tilde{S}(\sigma_L^{-2}(a_3)) \right) = \begin{pmatrix} \pi_1(a_0, \ldots, a_3) & 0 \\ 0 & \pi_2(a_0, \ldots, a_3) \end{pmatrix}
\]

for some multi-linear maps \( \pi_1, \pi_2: \mathcal{A}^{\otimes 4} \rightarrow \mathcal{A} \). Again using Proposition 5.1, we have

\[
\pi_1(a_0, \ldots, a_3) = a_0 \partial_H(a_1) \partial_e(\sigma_L^{-\frac{1}{2}}(a_2)) \partial_f(\sigma_L^{-\frac{3}{2}}(a_3)) - a_0 \partial_e(\sigma_L^{-\frac{1}{2}}(a_1)) \partial_H(\sigma_L^{-1}(a_2)) \partial_f(\sigma_L^{-\frac{3}{2}}(a_3)) + a_0 \partial_e(\sigma_L^{-\frac{1}{2}}(a_1)) \partial_f(\sigma_L^{-\frac{3}{2}}(a_2)) \partial_H(\sigma_L^{-2}(a_3)),
\]

and

\[
\pi_2(a_0, \ldots, a_3) = -a_0 \partial_H(a_1) \partial_f(\sigma_L^{-\frac{1}{2}}(a_2)) \partial_e(\sigma_L^{-\frac{3}{2}}(a_3)) + a_0 \partial_f(\sigma_L^{-\frac{1}{2}}(a_1)) \partial_H(\sigma_L^{-1}(a_2)) \partial_e(\sigma_L^{-\frac{3}{2}}(a_3)) - a_0 \partial_f(\sigma_L^{-\frac{1}{2}}(a_1)) \partial_e(\sigma_L^{-\frac{3}{2}}(a_2)) \partial_H(\sigma_L^{-2}(a_3)).
\]

Then by Theorem 6.3, and the \( \sigma_L \) invariance of \( \int_{[1]} \), we have

\[
\phi_{\text{res}}(a_0, a_1, a_2, a_3) = R \int_{[1]} \pi_1(a_0, \ldots, a_3) + R \int_{[1]} \pi_2(a_0, \ldots, a_3). \tag{15}
\]
Comparing Equations (15), (15), (15) with the expressions for the cocycles identified in Lemma 3.2 and Corollary 3.4 we find

$$\phi_{\text{res}} = q^2 R(\varphi + \varphi_{213} + \varphi_{231}) + R(\varphi_{132} + \varphi_{312} + \varphi_{321}).$$

The evaluation of this cocycle on the cycle $d\text{vol}$ (see Equation (2)) is a straightforward computation using the explicit expressions obtained. The result is

$$\langle \phi_{\text{res}}, d\text{vol} \rangle = 3R(q^{-1} + q).$$

**Concluding remark.** Recall that our residue functional $\tau$ was defined, via the functional $\Upsilon_w$, using the ultraviolet cutoff projection $P_1P_2$. There are other choices of cutoff projection that could be used to define a residue functional, and we thank the referee for their remarks on this point.

Indeed, the operator $D$ restricted to $\Psi_0\mathcal{H}$ coincides with the Dirac operator used in [KW]. Employing the cutoff projection $\Psi_0$ yields a new residue functional $\tau'$. Following the computations contained in [KW], $\tau'$ coincides with a multiple of the functional $\tau$ on products $a_0[D, a_1][D, a_2][D, a_3]$, albeit taking the residue in Equation (13) at $w = 2$ not $w = 3$. Our aim was, however, to attempt to reconcile the spectral and homological dimensions. Whether or not this is a fruitful strategy in a more general context has to be tested on further examples.
