ABSTRACT
Gelatin is a protein extracted from animal collagen tissues in animal skin, bones, ligaments, or connective tissue. Gelatin is highly digestible, so that it is potentially used as a raw material for making edible films. The edible film is a thin layer made for coating or placed on top or between edible food components or can be consumed. In producing edible films made from hydrocolloids, the quality of the films is often fragile, therefore requiring additives that act as plasticizers. A plasticizer is a liquid with a high boiling point that will give soft and flexible properties when mixed with a polymer. The polyol group, including glycerol, sorbitol, and polyethylene glycol (PEG), is commonly used as plasticizers for edible films. The main research results showed that different plasticizers had a significant effect on the physical characteristics of edible films, namely the water vapor transmission rate, but had no significant effect on the tensile strength, thickness, elongation, and chemical characteristics of edible films, namely water content. The best edible film made from Grouper skin gelatin was obtained at a concentration of 1% glycerol plasticizer with physical and chemical characteristics, including the tensile strength of 12.07 MPa, elongation of 67.33%, the thickness of 0.11 mm, water vapor transmission rate of 167.50 g/m²/day, and water content of 13.22%. The amino acid profile analysis results showed that the highest amino acid content of the edible film was glycine at 185,559.12 mg/kg. In comparison, the lowest amino acid was L-Tyrosine at 2,893.97 mg/kg.

KEY WORDS
Gelatin, edible film, glycerol, sorbitol, polyethylene glycol (PEG).

Optimal utilization of waste with low cost can create additional income, reduce fishery waste and increase the selling value of waste. One alternative that can be taken is to make gelatin from fish skin, one of which is Grouper skin. Fish skin contains collagen that produces gelatin when hydrolyzed (Ismail and Suprayitno, 2019). Gelatin is a protein extracted from animal collagen tissue in animal skin, bones, ligaments, or connective tissue. The addition of gelatin is highly important in diversifying food ingredients because of its high nutritional value, especially protein content, and low amino acids and fat content (Pantow et al., 2016). Gelatin functions as a stabilizer, thickener, emulsifier, gelling agent, edible coating, microencapsulation, foaming agent, and film former (Atma, 2016).

Gelatin is highly digestible, so that it is potentially used as a raw material for making edible films. Edible films can be made from three different types of constituent materials, namely hydrocolloids, lipids, and composites of both. The edible film is a thin layer made for coating or placed on top or between edible food components or can be consumed. In food products, edible films inhibit the transfer of water vapor and gas exchange, prevent loss of aroma and transfer of fat, improve physical characteristics, as a carrier for additives, and are environmentally friendly. The edible film is biodegradable packaging that is environmentally friendly and easy to decompose (Miwada et al., 2015). The manufacture of edible films uses not only the main constituent materials but also plasticizers.

In producing edible films made from hydrocolloids, the quality of the films is often fragile, therefore requiring additives that act as plasticizers to increase the plastic properties when the films are pulled (Mulyadi et al., 2016). A plasticizer is a liquid with a high boiling
point that will give soft and flexible properties when mixed with polymer (Arini et al., 2017). Appropriate types and concentrations of plasticizers will produce good film properties. The polyol group, including glycerol, sorbitol, and polyethylene glycol (PEG), is commonly used as plasticizers for edible films. This research was intended to develop gelatin from Grouper skin as a raw material for making edible films with different plasticizers to make it easier for people to apply it to packaging materials.

**MATERIALS AND METHODS OF RESEARCH**

The materials used in this research consisted of raw materials for the manufacture of gelatin, namely Grouper fish skin, citric acid (C6H8O7), distilled water, and water. Furthermore, the ingredients for making edible films were Grouper skin gelatin, glycerol, sorbitol, and polyethylene glycol (PEG).

This research employed an experimental method divided into two stages. The first stage was preliminary research aimed at finding the optimal concentration at each type of plasticizer, covering glycerol, sorbitol, and polyethylene glycol in the process of making edible films from Grouper skin gelatin. The second stage was the main research aimed at knowing the use of different plasticizers with optimal concentrations to produce edible films from Grouper skin gelatin with the best physical and chemical characteristics. Physical and chemical characteristics tests include thickness, tensile strength, elongation, water vapor transmission rate, water content, and amino acid profile.

The gelatin production began with preparing the raw material of Grouper fish skin and soaking it in warm water at 50° C for 30 minutes. The clean fish skin (100 g) was then weighed and cut into 1 cm² size. Furthermore, the fish skin was soaked again using a 1% concentration of citric acid with a ratio of 1:3 (w/v) for 24 hours. After finished, the fish skin was washed with running water until the pH was neutral, then extracted with a water bath at 60-70° C for 6 hours. The ratio between Grouper skin and distilled water was 1:3 (w/v). The next process was filtering the gelatin solution using a calico cloth. The filtered gelatin solution was poured into a baking tray to be dried using an oven at a temperature of 60° C for 48 hours. The obtained gelatin was then mashed using a blender and stored in a desiccator for further analysis.

The first stage in the collagen production was to prepare the Grouper skin gelatin obtained in this research. Then, 5 grams of gelatin was weighed and then dissolved using 100 mL of distilled water until dissolved. The gelatin solution was heated on a hot plate at 60° C for 15 minutes and stirred using a magnetic stirrer. Furthermore, variations in the concentration of plasticizers were added, namely 1% glycerol, 1.2% sorbitol, and 1% polyethylene glycol (PEG). All the ingredients mixed were stirred using a magnetic stirrer and reheated on a hot plate at a temperature of 60° C for 15 minutes until being homogenous. The mixture was then poured into an 18x8 cm baking tray to be dried using an oven at a temperature of 65° C for 18 hours. The next stage was to conduct the peeling process to release the films. The films were stored in a desiccator and ready for testing.

Thickness was measured using a micrometer with an accuracy of 0.01 mm. The measurement was carried out by placing the film between the jaws of the micrometer. The thickness measurement was made at 5 different points in each sample to get the average thickness of the edible film sample.

Tensile strength was measured using a Texture Analyzer. The thickness of the edible film specimen was measured using a micrometer and then affixed between the grips with an initial distance of 50 mm/ minute. The tensile strength was calculated by dividing the maximum force (F) applied to the film to tear (N) per unit area of the film (m). The tensile strength was calculated using the following formula:

\[
Tensile \, Strength \, (kgf/cm²) = \frac{F}{N}
\]
The edible film samples were attached firmly to the ends of the two clamps. The measuring area was set to the appropriate weight, and the recorder was set to zero (default). The test of edible film samples was done until they broke. Elongation is determined and calculated at the time the film breaks (expressed as a percentage). The formula for calculating elongation is as follows:

\[
\text{Elongation} \, (\%) = \frac{\text{Elongation of edible film} \, (cm)}{\text{The initial length of the edible film} \, (cm)} \times 100\%
\]

The rate of water vapor transmission to the film was measured by the gravimetric method. The first step was to cut the film samples to be tested according to size affixed to a container containing silica gel. Before that, the silica gel was dried at 105° C for 2 hours. The measurement was taken every day for one week using the following formula:

\[
\text{WVTR} = \frac{G}{1 \times A}
\]

Water content was analyzed using an oven. The porcelain cup was dried in the oven for 30 minutes, and then cooled in a desiccator for 15 minutes. Then, 5 grams of the sample was weighed in a cup and dried in an oven at 100° C under a pressure of not more than 10 mmHg for 5 hours or until the weight was constant. The cup and its content were then cooled in a desiccator and weighed. The water content was calculated using the following formula:

\[
\text{Water Content} \, (\%) = \frac{B - C}{B - A} \times 100\%
\]

Amino acid profile was analyzed using the UPLC method. 0.1 grams of the sample was weighed in a closed test tube, and then added with 5 mL of HCl 6 N and vortexed. The sample was flown with nitrogen gas. Furthermore, the tube containing the sample was put in an oven at 110° C for 22 hours. After cooling, the sample was transferred to a 50 mL volumetric flask and added with aquabidest (double-distilled water) to the border mark. The sample was filtered with a 0.45 μm filter membrane. The amino acid concentration was calculated using the following formula:

\[
\mu\text{mol AA} = \frac{\text{peak area of sample} \times \text{standard concentration} \times \text{volume}}{\text{standard peak area}}
\]

\[
\% \text{AA} = \frac{\mu\text{mol AA} \times Mr \text{AA} \times 100}{\mu\text{g sample}}
\]

**RESULTS AND DISCUSSION**

Based on Figure 1, the tensile strength values with the additions of 1% glycerol plasticizer (G(1)), 1.2% sorbitol plasticizer (S(1.2)), and 1% PEG plasticizer (P(1)) were 12.07 MPa, 9.29 MPa, and 8.07 MPa respectively. The addition of 1% glycerol plasticizer (G(1)) resulted in the highest tensile strength, while the addition of 1% PEG plasticizer (P(1)) resulted in the lowest tensile strength. The higher the concentration of plasticizer added, the lower the tensile strength. The addition of plasticizers caused plasticizer molecules to interact by forming hydrogen bonds in the chains between polymers, thereby reducing interactions between biopolymer molecules (Tanjung et al., 2020).

Figure 2 shows that the elongation values of the edible film with the additions of 1% glycerol plasticizer (G(1)), 1.2% sorbitol plasticizer (S(1.2)), and 1% PEG plasticizer (P(1)) were 67.33± 67.47%, 59.59±50.64%, and 1.14 ± 0.49% respectively. The addition of 1% glycerol plasticizer (G(1)) resulted in the highest elongation value, while the addition of 1% PEG plasticizer (P(1)) resulted in the lowest elongation value. The high elongation value indicates that the edible film produced is not easily broken because of its ability to maintain the given
load and tensile strength. The use of hydrocolloids can increase the breaking force and elongation because it produces a lubricating effect making edible film emulsion more elastic, flexible, and strong (Shinta et al., 2016).

Figure 3 shows that the thickness values of the edible film with the additions of 1% glycerol plasticizer (G(1), 1.2% sorbitol plasticizer (S(1.2), and 1% PEG plasticizer (P(1) were 0.11 ± 0.02 mm, 0.10 ±0.01 mm, and 0.09 ± 0.01 mm respectively. The addition of 1% glycerol plasticizer (G(1)) resulted in the highest thickness value, while the addition of 1% PEG plasticizer (P(1)) resulted in the lowest thickness value. The thickness of the edible film is influenced by the plasticizer used because plasticizers have hydrophilic properties that can increase the solubility and water vapor absorption ability of the edible film. Besides, plasticizer molecules play a role in destroying and restructuring intermolecular polymer tissues, causing a lot of space. Plasticizer molecules placed in the edible film matrix cavities will thicken the edible film (Suryadri et al., 2020).
Figure 4 shows that the water vapor transmission rates of the edible film with the additions of 1% glycerol plasticizer (G(1), 1.2% sorbitol plasticizer (S(1.2), and 1% PEG plasticizer (P(1) were 167.50 ± 22.46 g/m²/day, 38.57±22.07 g/m²/day, and 144.17 ± 22.60 g/m²/day respectively. The addition of 1% glycerol plasticizer (G(1) resulted in the highest water vapor transmission rate, while the addition of 1.2% sorbitol plasticizer (S(1.2) resulted in the lowest water vapor transmission rate. The Water Vapor Transmission Rate (WVTR) of edible films are significantly influenced by the properties of the polymer used. The more hydrophilic and cationic a polymer, the higher the WVTR of the film (Ningrum et al., 2020).

Based on Figure 5, the water content values of the edible film with the additions of 1% glycerol plasticizer (G(1), 1.2% sorbitol plasticizer (S(1.2), and 1% PEG plasticizer (P(1) were 13.22 ± 0.78%, 12.16 ± 1.90%, and 14.20 ± 1.70% respectively. The addition of 1% PEG plasticizer (P(1) resulted in the highest water content value, while the addition of 1.2% sorbitol plasticizer (S(1.2) resulted in the lowest water content value. The levels of water content in edible films are influenced by several factors, including basic ingredients and additives used in the film production process (Salimah et al., 2016).

Amino acid profile was analyzed to determine the amino acid composition contained in food ingredients. Amino acids can be found in foods containing protein. Amino acid content is influenced by the type, the observed organ, the age of harvest, and the physiological processes of the organism (Niccy et al., 2020).

As seen in the table 1, there were 15 amino acid types ranging from 4,200 mg/kg to 210,700 mg/kg. The highest amino acid result was Glycine (210,700 mg/kg), and the lowest amino acid result was L-Tyrosine (4,200 mg/kg). Meanwhile, the result of L-Proline amino acid reached 102,300 mg/kg. The main amino acid making up gelatin are glycine, proline, and hydroxyproline. According to Nasution et al. (2018), glycine and proline are the two main amino acids in gelatin, almost a quarter of the total amino acids in gelatin. Gelatin is made by partial hydrolysis of collagen. The alpha chain in collagen generally has a glycine-X-Y
repeating sequence. Proline often occurs in the X position. Therefore, these two amino acids are most abundant in gelatin. Grouper skin gelatin is then often used as a raw material in producing edible films.

Table 1 – The Analysis Results of the Gelatin Amino Acid Profile

| No. | Parameter       | Unit  | Result   |
|-----|----------------|-------|----------|
| 1   | L-Serine       | mg/kg | 26,300   |
| 2   | L-Glutamic Acid| mg/kg | 75,700   |
| 3   | L-Phenylalanine| mg/kg | 21,200   |
| 4   | L-Isoleucine   | mg/kg | 7,900    |
| 5   | L-Valine       | mg/kg | 16,700   |
| 6   | L-Alanine      | mg/kg | 86,000   |
| 7   | L-Arginine     | mg/kg | 80,600   |
| 8   | Glycine        | mg/kg | 210,700  |
| 9   | L-Lysine       | mg/kg | 25,800   |
| 10  | L-Aspartic Acid| mg/kg | 41,100   |
| 11  | L-Leucine      | mg/kg | 19,200   |
| 12  | L-Tyrosine     | mg/kg | 4,200    |
| 13  | L-Proline      | mg/kg | 102,300  |
| 14  | L-Threonine    | mg/kg | 23,700   |
| 15  | L-Histidine    | mg/kg | 7,100    |

Table 2 – The Results of the Amino Acid Profile of Edible Films

| No. | Parameter       | Unit  | Result   |
|-----|----------------|-------|----------|
| 1   | L-Serine       | mg/kg | 26,313.71|
| 2   | L-Glutamic Acid| mg/kg | 60,250.76|
| 3   | L-Phenylalanine| mg/kg | 21,897.08|
| 4   | L-Isoleucine   | mg/kg | 9,635.56 |
| 5   | L-Valine       | mg/kg | 15,646.85|
| 6   | L-Alanine      | mg/kg | 58,052.78|
| 7   | L-Arginine     | mg/kg | 67,279.30|
| 8   | Glycine        | mg/kg | 185,559.12|
| 9   | L-Lysine       | mg/kg | 18,128.10|
| 10  | L-Aspartic Acid| mg/kg | 31,193.59|
| 11  | L-Leucine      | mg/kg | 21,069.50|
| 12  | L-Tyrosine     | mg/kg | 2,893.97 |
| 13  | L-Proline      | mg/kg | 84,613.99|
| 14  | L-Threonine    | mg/kg | 15,861.99|
| 15  | L-Histidine    | mg/kg | 5,904.01 |

As seen in the table of the amino acid profile of the edible films made from Grouper skin gelatin above, there were 15 amino acid types ranging from 2,893.97 mg/kg to 185,559.12 mg/kg. The highest amino acid result was Glycine (185,559.12 mg/kg), and the lowest amino acid result was L-Tyrosine (2,893.97 mg/kg). The high content of glycine and L-Proline in edible films is due to the high content of glycine and L-Proline owned by gelatin. The gelatin structure in fish skin is dominated by amino acids, including 14% hydroxyproline, 16% proline, and 26% glycine. It depends on the composition of the collagen in the raw material. The triple helix collagen structure is assembled from specific polypeptides with the glycine-X-Y position, where the X position is filled with the proline amino acid, and the Y position is filled with the hydroxyproline amino acid (Firdayanti and Suprayitno, 2019). Gelatin with a high glycine and proline amino acids will have a higher gel strength. Both amino acids also have an important role in the physical properties of gelatin. The glycine content in gelatin is highly important in binding water when applied to products (Utomo and Suprayitno, 2019).

CONCLUSION

The best edible film made from Grouper skin gelatin is obtained at a concentration of 1% glycerol plasticizer with physical and chemical characteristics, including the tensile strength of 12.07 MPa, elongation of 67.33%, thickness of 0.11 mm, water vapor transmission rate of 167.50 g/m²/day, and water content of 13.22%. The results of amino acid profile analysis showed that the highest amino acid content of edible films was glycine at 185,559.12 mg/kg, while the lowest amino acid was L-Tyrosine at 2,893.97 mg/kg.
