STABILIZATION OF THE CATEGORY OF SIMPLICIAL OBJECTS IN CAT.

AMRANI ILIAS

Abstract. In this article, we define two equivalent new model structures on $s\text{Cat}$ the category of simplicial objects in $\text{Cat}$. Then we construct the corresponding stable model category of spectra $\text{Sp}^N(s\text{Cat})$ and make some links with the algebraic $K$-theory via the mapping space.

Introduction and main results

We start by introducing two Quillen equivalent new model structures on $s\text{Cat}$ (i.e., $[\Delta^{op}, \text{Cat}]$), the category of simplicial objects in $\text{Cat}$, which we will often call them simplicial categories. It is a discrete version of the diagonal model structure defined in [1, theorem 1.2], but we will go further in our investigations, mainly the stabilization process, as we will see later. Equipped with these new model structures, the mapping space map is closely related to the algebraic $K$-theory. In order to get a full analogy, we construct the stable category of spectra $\text{Sp}^N(s\text{Cat})$ following ideas of [7]. Then the mapping space $\text{map}_{\text{Sp}^N(s\text{Cat})}(\Sigma\infty S^0, C_{\bullet})$ is an infinity loop space, where $C_{\bullet}$ is a fibrant object in the model category $\text{Sp}^N(s\text{Cat})$. Roughly speaking $C_{\bullet}$ is a categorical $\Omega$-spectra. We recall, that the $K$-theory of an exact category or more generally a Waldhausen category with isomorphisms produces an $\Omega$-spectra. Let’s $C$ be a Waldhausen category, then the Waldhausen ”suspension” $S_{\bullet}C$, is a simplicial category and the $K$-theory spectra is given by the following sequence [8]:

$$\{\Omega \text{diag}_{\bullet} S_{\bullet}C, \text{diag}_{\bullet} S_{\bullet}C, \ldots, \text{diag}_{\bullet} S_{\bullet}C, \ldots\}$$

which is an $\Omega$-spectra i.e., a fibrant object in the stable model category $\text{Sp}^N(s\text{Set})$.

In section 1 we construct the diagonal model structure on $s\text{Cat}$. We prove the following theorem.

Theorem A: (diagonal model structure [1]) The category of simplicial categories $s\text{Cat}$ is a cofibrantly generated model category where

1. a morphism $f : C_{\bullet} \rightarrow D_{\bullet}$ is a weak equivalence (resp. fibration) if and only if $\text{diag}_{\bullet} \text{iso}(f)$ is a weak equivalence (resp. fibration) in $s\text{Set}$.

2. The generating (acyclic) cofibrations in $s\text{Cat}$ are given by the image of generating (acyclic) cofibration in $s\text{Set}$ via the functor $\pi_{\bullet}d_{\bullet}$.

In section 2 we prove that the new model structure on $s\text{Cat}$ is cellular and proper.
Theorem B: (additional properties\[2.14,2.8\]) The diagonal model structure on $s\text{Cat}$ is left proper and cellular.

In section 3 we equip the category of simplicial categories with a new model category equivalent to the diagonal one (same weak equivalences), but having the advantage to be well tensored and cotensored with respect to the model category $s\text{Set}$. We establish the following theorem:

**Theorem C:** (\$W\$-model structure 3.6) There exists a cofibrantly generated model structure on $s\text{Cat}$ induced by the adjunction 

\[
\begin{array}{ccc}
\text{sSet} & \xrightarrow{\pi \ast} & s\text{Cat} \\
\Downarrow & & \Downarrow \\
W_{N, \text{iso}} & & \\
\end{array}
\]

Moreover, the $\overline{W}$-model structure on $s\text{Cat}$ is Quillen equivalent to the diagonal model structure, left proper and cellular.

In section 4 construct and explicit suspension functor and a loop functor in the pointed $\overline{W}$-model category $s\text{Cat}$.

**Theorem D:** (compatible (co)tensorization) 4.5 If $X \ast$ is a pointed simplicial set, then the functor 

\[- \ast X : s\text{Cat}_\ast \to s\text{Cat}_\ast\]

is a left Quillen functor, where $s\text{Cat}$ is equipped with $\overline{W}$-model structure. Moreover, the functor $- \ast X$ has a right Quillen adjoint.

In the final section 5 we prove our main theorem, roughly speaking we construct a the stable model category of spectra $\text{Sp}^N(s\text{Cat}_\ast)$ and relate the mapping space $\text{map}_{\text{Sp}^N(s\text{Cat}_\ast)}$ to the algebraic $\mathbb{K}$-theory:

**Theorem E:** (stabilization 5.4) There is a cofibrantly generated stable model category structure on $\text{Sp}^N(s\text{Cat}_\ast, \Sigma)$.

As consequence of the last theorem is that any fibrant object $D^\ast$ in $\text{Sp}^N(s\text{Cat}_\ast, \Sigma)$ has the property that $\Omega \text{diag}_N \text{iso} D^{n+1}$ is equivalent to $\text{diag}_N \text{iso} D^n$. It means that $D^{n+1}$ looks like $S \ast D^n$, the Whaldhausen suspension of $D^n$. We express the right formulation in the following corollary:

**Corollary F:** (relation to algebraic $\mathbb{K}$-theory 5.13) For any fibrant object $D^\ast$ in $\text{Sp}^N(s\text{Cat}_\ast, \Sigma)$, we have the following isomorphisms in $\text{Ho}(\text{Set})$:

1. $\text{map}_{s\text{Cat}}(\Sigma S^0, D^{n+1}) \simeq \text{map}_{s\text{Cat}}(S^0, \Omega D^{n+1}) \simeq \text{diag}_N \text{iso} \Omega D^{n+1}$.
2. $\text{map}_{s\text{Cat}}(\Sigma S^0, D^{n+1}) \simeq \Omega \text{diag}_N \text{iso} D^{n+1}$.
3. $\text{map}_{s\text{Cat}}(\Sigma S^0, D^{n+1}) \simeq \text{map}_{s\text{Cat}}(S^0, D^n) \simeq \text{diag}_N \text{iso} D^n$. 
The appendix is about some easy facts about small objects in different categories. We made an effort to treat all technical details in order to establish our results without ambiguity.

Acknowledgment: I would like to express my gratitude to my former supervisor, Professor Kathryn Hess for all her corrections and suggestions.

1. Diagonal model structures on sCat

1.1. framework.

Notation 1.1. (1) Objects of the category Cat are denoted by \( A, B, C, \ldots \).
(2) Objects of the category sSet are denoted by \( X, Y, Z, \ldots \) or simply by \( X, Y, Z, \ldots \) if there is no confusion.
(3) Objects of sCat will be denoted by \( A_\bullet, B_\bullet, C_\bullet, \ldots \).
(4) Generic categories by \( A, B, C, \ldots \).
(5) Finally objects of the category of (non symmetric) spectra \( \text{Sp}^N(\text{sCat}_*) \) are denoted by \( A_\bullet^\bullet, B_\bullet^\bullet, C_\bullet^\bullet, \ldots \).

In all what will follow, we assume that the category of small Cat is equipped with Joyal-Therny model structure. Roughly speaking, the weak equivalences are equivalences of categories, the cofibrations are functors injective on the set of objects and the fibrations are Grothendieck iso-fibrations. This model structure is in fact simplicial monoidal close cofibrantly generated model structure, where all object are fibrant and cofibrant and consequently proper but not cellular.

We use the standard Quillen model structure on the category of simplicial sets sSet. The weak equivalences are morphisms which induce isomorphisms on homotopy groups, cofibrations are monomorphisms and fibrations are Kan fibrations. Equipped with this model structure, the category of simplicial sets is simplicial monoidal closed cofibrantly generated model category, where all objects are cofibrant and Kan complexes are the fibrant objects. This model structure is proper and cellular.

In order to construct a model structure on the category of simplicial categories sCat = [\( \Delta^{op}, \text{Cat} \)] we use the fundamental lemma of transferring model structure via an adjunction.

Lemma 1.2. [\( \text{[10], proposition 3.4.1} \)] Let \( \mathcal{M} \) be a cofibrantly generated model structure and let

\[
\begin{array}{cc}
\mathcal{M} & \xrightarrow{G} \mathcal{C} \\
\xrightarrow{F} &
\end{array}
\]

be an adjunction and define a class of weak equivalences and fibrations as follow:

(1) WE the class of morphisms in \( \mathcal{C} \) such that there image under \( F \) is a weak equivalence in \( \mathcal{M} \).

(2) Fib the class of morphisms in \( \mathcal{C} \) such that there image under \( F \) is a fibration in \( \mathcal{M} \).

Suppose that the following condition are verified:

(1) The domains of \( G(i) \) are small relatively to \( G(I) \) for all \( i \in I \) and the domains of \( G(j) \) are small relatively to \( G(J) \) for all \( j \in J \).
(2) The functor $F$ commutes with directed colimits i.e.,
$$F\text{colim}(\lambda \to C) = \text{colim}F(\lambda \to C).$$

(3) Any transfinite composition of weak equivalences in $\mathcal{M}$ is again a weak equivalence.

(4) The pushout of $G(j)$ along any morphism $f$ in $C$ is an element of $\text{WE}$.

Then $C$ form is model category, where weak equivalences (resp. fibrations) are $\text{WE}$ (resp.$\text{Fib}$), moreover $C$ is cofibrantly generated, where the generating cofibration are $G(1)$ and generating trivial cofibrations are $G(J)$.

1.2. Diagonal model structure.

Definition 1.3. The $\pi : \text{sSet} \to \text{Cat}$ which associate to a simplicial set $K_\bullet$ its fundamental groupoid $\pi(K_\bullet)$, where the objects are 0-simplicies $K_0$, and the generating isomorphisms are $t : d_1x \to d_0x$ for each 1-simplex $t$ in $K_1$. The generators are submitted to the relation $d_0l \circ d_2l = d_1l$ for all 2-simplices $l$ in $K_2$.

The functor $\pi$ admits a right adjoint $N\bullet\text{iso}$ which associates to $C$ the nerve of the underlying groupoid $\text{iso}C$.

The previous adjunction

$$\text{sSet} \xrightarrow{\pi} \text{Cat} \xleftarrow{N\bullet\text{iso}}$$

extends naturally to an adjunction of bisimplicial sets and the category of simplicial objects in $\text{Cat}$.

$$\text{sSet}^2 \xrightarrow{\pi\bullet d_*} \text{Cat} \xleftarrow{N\bullet\text{iso}} \text{sSet}$$

where $\pi\bullet(K_\bullet, n) = \pi(X_\bullet, n)$ and $N\bullet\text{iso}$ is applied level-wise.

Moerdijk proved that there is a model structure on the category of bisimplicial sets Quillen equivalent to the standard model structure on simplicial sets ([4], chapter 4, section 3). This model structure is obtained by the following adjunction:

$$\text{sSet} \xrightarrow{d_*} \text{sSet}^2 \xleftarrow{\text{diag}}$$

Theorem 1.4. The category of simplicial categories $\text{sCat}$ is a cofibrantly generated model category where

1. a morphism $f : C_\bullet \to D_\bullet$ is a weak equivalence (resp. fibration) if and only if $\text{diag}N_\bullet\text{iso}(f)$ is a weak equivalence (resp. fibration) in $\text{sSet}$.
2. The generating (acyclic) cofibrations in $\text{sCat}$ are given by the image of generating (acyclic) cofibration in $\text{sSet}$ via the fonctor $\pi\bullet d_*$.

Lemma 1.5. If $j$ is an generating acyclic cofibration in $\text{sSet}^2$, then $\pi\bullet(j)$ is an equivalence in $\text{sCat}$.

Proof. The generating acyclic cofibrations in $\text{sSet}^2$ equipped with Moerdijk’s model structure are given by

$$d_*\Lambda^n_i \to d_*\Delta^n = \Delta^n, \ i \in \{0, 1, \ldots, n\}.$$ 

More precisely:

$$\bigsqcup_{\beta \in \Lambda^n_i} C_\beta \to \bigsqcup_{\beta \in \Delta^n} \Delta^n,$$
where $C_\beta$ is a contractible subcomplex of $\Lambda^n_i$. Consider the following commutative diagram:

\[
\begin{array}{c}
\bigsqcup_{\beta \in \Lambda^n_i} C_\beta \xrightarrow{pr} \bigsqcup_{\beta \in \Lambda^n_i} * \\
\downarrow d_* j \quad \sim \downarrow j \\
\bigsqcup_{\beta \in \Delta^n} \Delta^n \xrightarrow{pr} \bigsqcup_{\beta \in \Delta^n} *
\end{array}
\]

The projections are weak equivalences of simplicial sets degree by degree, and so diagonal equivalences. Obviously, we have also that $j$ is a diagonal equivalence. We conclude that $d_* j$ is a diagonal equivalence. We apply to the previous diagram the functor $N_\bullet \pi$:

\[
\begin{array}{c}
\bigsqcup_{\beta \in \Lambda^n_i} N_\bullet \pi C_\beta \xrightarrow{pr} \bigsqcup_{\beta \in \Lambda^n_i} * \\
N_\bullet \pi d_* j \quad \sim \downarrow j \\
\bigsqcup_{\beta \in \Delta^n} N_\bullet \pi \Delta^n \xrightarrow{pr} \bigsqcup_{\beta \in \Delta^n} *
\end{array}
\]

Since $C_\beta$ is a connected subcomplex of $\Lambda^n_i$, the canonical projection $\pi C_\beta \to *$ is an equivalence of categories and induces an equivalence of nerves. Consequently, the horizontal arrows are equivalence degree wise, and so diagonal equivalences. We conclude that $N_\bullet \pi d_* (j)$ is also a diagonal equivalence. Finally, $\pi (j)$ is a weak equivalence in $s\text{Cat}$. □

**Definition 1.6.** Let $\mathcal{M}$ be a category with a class of weak equivalences. A commutative square

\[
\begin{array}{c}
A \\
\downarrow \\
B \\
\downarrow \longrightarrow \\
C \\
\downarrow \\
D
\end{array}
\]

in $\mathcal{M}$ is homotopically cocartesian if the universal morphism $B \bigsqcup_A C \to D$ is a weak equivalence in $\mathcal{M}$.

**Lemma 1.7.** Let $f : A \to B$ a fully faithful inclusion of groupoids. Consider the following pushout diagram in $\text{Cat}$:

\[
\begin{array}{c}
A \\
\downarrow f \\
B \\
\downarrow \\
C \\
\downarrow \\
D = B \sqcup_A C.
\end{array}
\]

Then the two diagrams

\[
\begin{array}{c}
A = \text{iso} A \longrightarrow \text{iso} C \\
\downarrow \text{iso} f \\
B = \text{iso} B \longrightarrow \text{iso} D \\
\downarrow \\
N_\bullet \text{iso} A = N_\bullet \text{iso} A \longrightarrow N_\bullet \text{iso} C \\
\downarrow N_\bullet \text{iso} f \\
N_\bullet \text{iso} B = N_\bullet \text{iso} B \longrightarrow N_\bullet \text{iso} D
\end{array}
\]

are homotopically cocartesian in $\text{Cat}$ and respectively in $s\text{Set}$. 
Proof. The hypothesis on the groupoids $A$ and $B$ imply that we can decompose in $B^1 \sqcup B^2$ such $f : A \to B_1$ is a trivial cofibration in $\text{Cat}$. So, $D = (C \sqcup_A B_1) \sqcup B^2$. Let's define $D = B^1 \sqcup C$, then $D = D' \sqcup B^2$. The functor $C \to C \sqcup_A B_1$ is an equivalence of categories, injective on objects. It follows that $\text{iso} C \to \text{iso}(C \sqcup_A B_1)$ is a weak equivalence, consequently, the induced functor $\text{iso} C \sqcup_A B_1 \to \text{iso}(C \sqcup_A B^1)$ is a weak equivalence in $\text{Cat}$. Finally the second induced functor

$$\text{iso} C \sqcup_A B_1 = \text{iso} C \sqcup_A B^1 \sqcup B^2 \to \text{iso}(C \sqcup_A B^1)$$

is an equivalence of categories.

Now, we apply the functor $N_*$ to the initial diagram:

We observe that $N_* B \sqcup_{N_* A} N_* \text{iso} C = (N_* B^1 \sqcup_{N_* A} N_* \text{iso} C) \sqcup N_* B^2$, and $N_* A \to N_* B^1$ is a trivial cofibration by definition of $B^1$. So, the morphism $N_* \text{iso} C \to N_* B^1 \sqcup_{N_* A} N_* \text{iso} C$ is a weak equivalence, since $s\text{Set}$ is a model category. On the other hand, $N_* \text{iso} C \to N_* \text{iso}(B^1 \sqcup_A C)$ is a weak equivalence in $s\text{Set}$, because it is the nerve of an equivalence of categories. Consequently, the induced map $N_* B^1 \sqcup_{N_* A} N_* \text{iso} C \to N_* \text{iso}(B^1 \sqcup_A C)$ is a weak equivalence of simplicial sets. We conclude that morphism of simplicial sets

$$t : N_* B \sqcup_{N_* A} N_* \text{iso} C = N_* B^2 \sqcup N_* B^1 \sqcup_{N_* A} N_* \text{iso} C \to N_* B^2 \sqcup N_* D' = N_* \text{iso} D$$

is a weak equivalence of simplicial sets.

Lemma 1.8. Let $j : A \to B$ be a generating acyclic cofibration in $s\text{Cat}$. Then the pushout of $j$ along any morphism $A \to C$ is a weak equivalence.

Proof. First of all, We remark that any acyclic generating cofibration in $s\text{Cat}$ verify degree by degree the hypothesis of lemma 1.7. Consider the following pushout $s\text{Cat}$:

$$\begin{array}{ccc}
A & \to & C \\
\downarrow^{j} & & \downarrow^{j'} \\
B & \to & D
\end{array}$$

Applying the functor $\text{diag}N_* \text{iso}$ to the precedent pushout, we obtain a commutative diagram in $s\text{Set}$:
since the colimits in \( \mathbf{sCat} \) are computed degree wise. Applying lemma 1.7 (degree by degree, we have that \( t \) is a degree wise equivalence in \( \mathbf{sSet} \), and so \( \text{diag}(t) \) is a weak equivalence in \( \mathbf{sSet} \). On the other hand, \( \text{diag}_N \text{iso}(j) \) is a cofibration of simplicial sets, since \( N \text{iso}(j) \) is a degree wise monomorphism and it is a diagonal weak equivalence by [1.5]. Consequently, \( s \) is a weak equivalence. By the property 2 out of 3, we conclude that \( l \) is a weak equivalence.

\[ \square \]

Finally, we can prove that \( \mathbf{sCat} \) is a cofibrantly generated model category

**Proof of the Theorem [1.2]** The lemma [1.2] permits to conclude that \( \mathbf{sCat} \) is a cofibrantly generated model category since,

1. The hypothesis (1) is a consequence of [A.4]
2. The hypothesis (2) is a consequence of [A.3]
3. The hypothesis (3) is a consequence of the fact that in \( \mathbf{sSet} \) a transfinite composition of weak equivalences is again a weak equivalence.
4. The hypothesis (4) is a consequence of [1.8]

\[ \square \]

2. ADDITIONAL PROPERTIES OF THE DIAGONAL MODEL STRUCTURE ON \( \mathbf{sCat} \)

In this section, we will establish some properties of the model structure in \( \mathbf{sCat} \), such that left and right properness and cellularity.

2.1. **Cofibrations in \( \mathbf{sCat} \)**. In this paragraph, we describe some properties of cofibrations in \( \mathbf{sCat} \) in order to prove that new model category is left proper. The simplicial set \( \partial \Delta^n \) is generated by \( (d_i e_n \text{ avec } 0 \leq i \leq n \text{ where } e_n \text{ is the only non degenerated } n-\text{simplex of } \Delta^n) \). The bisimplicial set \( d \partial \Delta^n \) is generated by \( (d_i e_n, d_i e_n) \). Following the same strategy as in ([4], chapter 4, 3.3), \( d \partial \Delta^n \) can be described as

\[ \bigcup_{\sigma \in \partial \Delta^n} C^\sigma, \]

where the simplicial set \( C^\sigma \) is generated by the faces \( d_i e_n \) which contain \( \sigma \). Notice that the number of faces with this property is strictly less than \( n + 1 \), this implies that \( C^\sigma \rightarrow \ast \) is a weak equivalence. Moreover, \( \pi(C^\sigma) \) is a groupoid equivalent to the trivial groupoid \( \ast \), more precisely, between to objects of the category \( \pi(C^\sigma) \) there is exactly one isomorphism.

Now, we give the fundamental property of cofibrations in \( \mathbf{sCat} \)

**Lemma 2.1**. The cofibrations in \( \mathbf{sCat} \) are inclusions of categories i.e., the cofibrations are injective on objects and morphisms.
Proof. Let $i : A_* \to B_*$ be a generating cofibration in $\text{sCat}$. Degreewise, the generating cofibrations in $\text{sCat}$ have the property that they are inclusions of categories. Moreover, we have a decomposition of $B_n$ in $B^1_n \sqcup B^2_n$ such that $i_n : A_n \to B^1_n$ is a trivial cofibration in $\text{Cat}$. But all objects in $\text{Cat}$ are fibrant, this implies that we have a retraction. Consequently the pushout of $i : A_* \to B_*$ along any functor $f : A_* \to C_*$ is an inclusion degree by degree, since the colimits in $\text{sCat}$ are computed degreewise. The transfinite composition of inclusions in $\text{sCat}$ is again an inclusion and the $I - \text{Cell}$ are inclusion of categories. By the same way the retracts of $I - \text{Cell}$ are also inclusion of categories. We conclude that cofibrations in $\text{sCat}$ are inclusions of categories. $\square$

Lemma 2.2. Let $i : A_* \to B_*$ be a cofibration in $\text{sCat}$, and consider the following pushout diagram in $\text{sCat}$:

\[
\begin{array}{ccc}
A_* & \longrightarrow & C_* \\
\downarrow & & \downarrow \\
B_* & \longrightarrow & D_*
\end{array}
\]

Then the functor $N_* \text{iso}$ sends this pushout to a homotopically cocartesian square in $\text{sSet}$ equipped with projective model structure.

Proof. The pushouts in $\text{sCat}$ are computed degreewise. The cofibrations in $\text{sCat}$ verify the same hypothesis of 1.7 degreewise. $\square$

Remark 2.3. Consider a commutative diagram in a category $\mathcal{M}$:

\[
\begin{array}{ccc}
A & \longrightarrow & C \\
\downarrow & & \downarrow \\
B & \longrightarrow & D
\end{array}
\]

where both squares are pushouts. Then the following square

\[
\begin{array}{ccc}
A & \longrightarrow & C' \\
\downarrow & & \downarrow \\
B & \longrightarrow & D'
\end{array}
\]

is also a pushout diagram in $\mathcal{M}$.

Lemma 2.4. With the same notations as in 2.2 and $A \to B$ verifying the same hypothesis as in 1.7 then the natural morphisms

$$
N_* B \sqcup_{N_* A} N_* \text{iso} C \to N_* D \sqcup_{N_* \text{iso} C} N_* \text{iso} C'
$$

and

$$
N_* \text{iso} D \sqcup_{N_* \text{iso} C} N_* \text{iso} C' \to N_* \text{iso} D'
$$

are weak equivalences in $\text{sSet}$.

Proof. By 1.7 the morphism $N_* B \sqcup_{N_* A} N_* \text{iso} C \to N_* \text{iso} D$ is an equivalence. Moreover $N_* \text{iso} C \to N_* B \sqcup_{N_* A} N_* \text{iso} C$ and the morphism $N_* \text{iso} C \to N_* \text{iso} D$ are cofibrations in $\text{sSet}$. Since $\text{sSet}$ is left proper, we conclude that

$$
(N_* B \sqcup_{N_* A} N_* \text{iso} C) \sqcup_{N_* \text{iso} C} N_* \text{iso} C' \to N_* \text{iso} D \sqcup_{N_* \text{iso} C} N_* \text{iso} C'
$$
is a weak equivalence. To show the other equivalence, it is sufficient to remark that
\[(N_*B \sqcup_{N_*A} N_*\text{iso}C) \sqcup_{N_*\text{iso}C} N_*\text{iso}C' = N_*B \sqcup_{N_*A} N_*\text{iso}C' \rightarrow N_*\text{iso}D']

is an equivalence by [1.7] and by the property "2 out of 3"
\[N_*\text{iso}D \sqcup_{N_*\text{iso}C} N_*\text{iso}C' \rightarrow N_*\text{iso}D'

is a weak equivalence. □

**Corollary 2.5.** The simplicial version of lemma [2.4] if we replace \(f : A \rightarrow B\) by \(i : A_* \rightarrow B_*\) in sCat verifying the same hypothesis degrewise, then
\[N_*B_* \sqcup_{N_*A_*} N_*\text{iso}C_*' \rightarrow N_*\text{iso}D_*

and
\[N_*\text{iso}D_* \sqcup_{N_*\text{iso}C_*} N_*\text{iso}C_*' \rightarrow N_*\text{iso}D_*'

are degreewise weak equivalences.

**Proof.** Apply [2.4] degree by degree. □

### 2.2. Properness of sCat.

We prove that sCat equipped with the model structure of [1.3] is left proper.

**Lemma 2.6.** Let \(i : A_* \rightarrow B_*\) an element of I − Cell in sCat. The functor diag\(N_*\text{iso}\) sends the following pushout in sCat:

\[
\begin{array}{ccc}
A_* & \longrightarrow & C_* \\
\downarrow & & \downarrow \\
B_* & \longrightarrow & D_*
\end{array}
\]

to a homotopically cocartesian square in sSet.

**Proof.** First of all, \(A_* \rightarrow B_*\) is a transfinite composition of cofibrations of the form
\[A_* = C^0 \rightarrow \ldots A_*^s \rightarrow A_*^{s+1} \rightarrow A_*^{s+2} \rightarrow \ldots\]

We denote \(A_*^s \sqcup_{A_*} C_*^s\) by \(C_*^s\). By the corollary [2.5]
\[N_*\text{iso}A_*^s \sqcup_{N_*\text{iso}A_*} N_*\text{iso}C_*^s \rightarrow N_*\text{iso}C_*^s\]
is a weak equivalence, moreover, \(N_*\text{iso}C_*^s \rightarrow N_*\text{iso}C_*^{s+1}\) is an inclusion of bisimplicial stes. Knowing that \(N_*\text{iso}\) commutes with directed colimits, and that diag\(N_*\text{iso}C_*^s\) → diag\(N_*\text{iso}C_*^{s+1}\) is a cofibration in sSet, we conclude that :
\[\text{diag}(N_*\text{iso}B_* \sqcup_{N_*\text{iso}A_*} N_*\text{iso}C_*) \rightarrow \text{diag}N_*\text{iso}D_*

is an equivalence in sSet □

**Corollary 2.7.** Let \(i : A'_* \rightarrow B'_*\) be any cofibration in sCat. The functor diag\(N_*\text{iso}\) sends the following pushout in sCat:

\[
\begin{array}{ccc}
A'_* & \longrightarrow & C_* \\
\downarrow & & \downarrow \\
B'_* & \longrightarrow & D_*
\end{array}
\]

to a homotopy cocartesian square.
Proof. The cofibration $i' : A' \to B'$ is a retract of a $I-$cell cofibration $i : A \to B$. We denote $B \sqcup_A C = M$, and $B' \sqcup_A C' = D$. There is an induced retract:

$$
\begin{array}{c}
N \cdot B \cong N \cdot A \sqcup N \cdot C \\
\downarrow i \\
N \cdot M \\
\downarrow g \\
N \cdot D
\end{array}
$$

By lemma 2.6, we have that $\text{diag}(t)$ is an equivalence, so $\text{diag}(g)$ is also an equivalence in $\text{sSet}$. □

Corollary 2.8. The model category $\text{scat}$ is left proper.

Proof. Let $A \to B$ be a cofibration and let $f : A \to C$ be an equivalence in $\text{scat}$. It is sufficient to consider the following pushout :

$$
\begin{array}{c}
\text{diag}(N \cdot A) \\
\downarrow i \\
\text{diag}(N \cdot C)
\end{array}
\quad \text{and} \quad
\begin{array}{c}
\text{diag}(N \cdot B) \\
\downarrow g \\
\text{diag}(N \cdot M)
\end{array}
\quad \text{and} \quad
\begin{array}{c}
\text{diag}(N \cdot D) \\
\downarrow h \\
\text{diag}(N \cdot A)
\end{array}
$$

We have that $i$ is a cofibration in $\text{Set}$ since $N \cdot A \to N \cdot B$ is injective in $\text{Set}$. But $f$ is an equivalence and $\text{Set}$ is proper, this implies that $g$ is an equivalence. By the corollary 2.7, $t$ is a weak equivalence, this implies that $h$ is a weak equivalence and finally that $\text{scat}$ is left proper. □

Lemma 2.9. The model category $\text{scat}$ is right proper.

Proof. This fact is much more easier that the left properness. Consider the pullback diagram in $\text{scat}$:

$$
\begin{array}{c}
C \times_A D \\
\downarrow f \\
A
\end{array}
$$

Our goal is to show that $i$ is a weak equivalence. Applying the functor $\text{diag} N \cdot$ which commutes with limits, we obtain a pullback diagram in $\text{Set}$, such that $\text{diag} N \cdot (f)$ is a fibration by definition of model structure on $\text{scat}$. Since $\text{Set}$ is right proper, we conclude that $\text{diag} N \cdot (i)$ is also a weak equivalence, and so $\text{scat}$ is right proper. □

2.3. Cellularity of $\text{scat}$. This paragraph is an other step of our comprehension of cofibrations in the model category $\text{scat}$. We will prove the cellularity property. This step is crucial in order to consider the left Bousfield localization and stabilization of the model category $\text{scat}$.

Definition 2.10. A cofibrantly generated model category is cellular if it verifies the following conditions:
The domains and codomains of I are compact (cf \cite{5} 11.4.1);
the domain of the generating acyclic cofibrations J are small with respect
to I (cf \cite{5} 10.5.12); and
the cofibrations are effective monomorphisms (cf \cite{5} 10.9.1).

Lemma 2.11. The cofibrations and acyclic cofibrations of $s\text{Cat}$ verify the first
hypothesis of the definition 2.10.

Proof. Let $C_\bullet$ a domain (codomain) of an element in I. By definition $C_\bullet$ has the
form $\pi d_.X_\bullet$, where $d_.$ is the left adjoint to $\text{diag}$. Let $f : D_\bullet \to D_\bullet'$ be a I-cell complex. We have to show that any morphism $g : C_\bullet \to D_\bullet'$ is factorized through a sub complex of $f$ for a certain cardinal $\gamma$. The morphism $f$ is a transfinite composition of elements of $I$-cell which are inclusions categories degree by degree

$$D_\bullet \to D_1 \to \ldots \to D_\beta \to D_{\beta+1} \to \ldots \to D_\bullet'.$$

The factorization $g$ by a sub complex of $f$ is equivalent to factorization of the
adjoint of $g$, denoted by, $g' : d_\cdot X_\bullet \to N\cdot isod_\bullet$ by a sub complex of

$$N\cdot isod_\bullet \to N\cdot isod_1 \to \ldots \to N\cdot isod_\beta \to N\cdot isod_{\beta+1} \to \ldots.$$  

By the same argument, a factorization of $g'$ is equivalent to factorization of the
adjoint map $g'' : X_\bullet \to \text{diag}N\cdot isod_\bullet$ by a sub complex

$$\text{diag}N\cdot isod_\bullet \to \text{diag}N\cdot isod_1 \to \ldots \to \text{diag}N\cdot isod_\beta \to \text{diag}N\cdot isod_{\beta+1} \to \ldots$$

which is a transfinite composition of monomorphisms in $s\text{Set}$, since by \cite{6} the
cofibrations in $s\text{Cat}$ are inclusions of categories degree by degree. But the objects $\Delta^n$ and $\partial\Delta^n$ are compact in $s\text{Set}$. We conclude that $g$ has a factorization through a sub complex of $f$.

Lemma 2.12. The cofibrations and acyclic cofibrations in $s\text{Cat}$ the second hypo-
thesis of the definition 2.10.

Proof. Let $\pi d_\cdot X_\bullet$ be a domain of an element of J. We have to show that this
domain is small relatively to I-cell for a certain cardinal $\lambda$. We have the following
isomorphisms:

$$\colim_{\beta<\lambda} \text{hom}_{s\text{Cat}}(\pi d_\cdot X_\bullet, D_\beta) \to \colim_{\beta<\lambda} \text{hom}_{s\text{Set}}(X_\bullet, \text{diag}N\cdot isod_\beta)$$

$$\colim_{\beta<\lambda} \text{hom}_{s\text{Set}}(X_\bullet, \text{diag}N\cdot isod_\beta) \to \text{hom}_{s\text{Set}}(X_\bullet, \text{diag}N\cdot isod_{\beta+1})$$

The first isomorphism is by adjunction, the second isomorphism is a consequence
of the fact that all object in $s\text{Set}$ are small for a $\lambda$ (cf \cite{6} lemme 3.1.1), and the
functor $\text{diag}$ commutes with colimits and that the functor $N\cdot isod$ commutes with
directed colimits.

Lemma 2.13. The cofibrations in $s\text{Cat}$ are effective monomorphisms.

Proof. Let $C_\bullet \hookrightarrow D_\bullet$ be a cofibration in $s\text{Cat}$ (in particular an inclusion
of categories). Now, we compute the equalizer of the following diagram:

$$D_\bullet \to D_\bullet \sqcup_{C_\bullet} D_\bullet.$$
where both morphisms are inclusion of categories coming from the pushout diagram:

\[
\begin{array}{ccc}
C & \xrightarrow{i} & D \\
\downarrow \scriptstyle{\iota} & & \downarrow \scriptstyle{\iota} \\
D & \xrightarrow{i} & D \cup_C D
\end{array}
\]

We affirm that the equalizer is given exactly by

\[
C \xrightarrow{i} D \xrightarrow{\iota D} D \cup_C D.
\]

First of all, it is a commutative diagram. Suppose that \(C'\) is an other candidate for the equalizer. Since the functor \(\text{Ob} : \text{sCat} \rightarrow \text{sSet}\) commutes with limits and colimits, there exists a unique morphism \(t\) making the following diagram commuting:

\[
\begin{array}{ccc}
\text{Ob}C' & \xrightarrow{\iota C'} & \text{Ob}(D) \\
\downarrow \scriptstyle{\iota} & & \downarrow \scriptstyle{\iota} \\
\text{Ob}C & \xrightarrow{\iota C} & \text{Ob}(D) \cup_{\text{Ob}C} \text{Ob}D.
\end{array}
\]

In fact, the cofibrations in \(\text{sCat}\) are injective on objects\(^2\) and \(\text{sSet}\) is cellular\(^5\). Suppose now \(\gamma\) a morphism in the category \(C'\) such that \(i_1 F(\gamma) = i_2 F(\gamma)\). Since \(i_1 : C \rightarrow D \cup_C D\) and \(i_2 : C \rightarrow D \cup_C D\) are injections of categories, it implies that \(F(\gamma)\) is, in fact, a morphism in \(C\). We conclude that any morphism \(F : C' \rightarrow D\) in \(\text{sCat}\) such that \(i_1 F = i_2 F\) has a unique factorization as a composition

\[
C' \rightarrow C \rightarrow D.
\]

\[
\square
\]

**Corollary 2.14.** Equipped with the model structure \(^1\), The category \(\text{sCat}\) is cellular.

**Remark 2.15.** At this stage, we should remark that the model category on \(\text{Cat}\) constructed by A. Joyal and refined by C. Rezk is not a cellular. In order to show the non cellularity of \(\text{Cat}\), we consider the following example where \(C \rightarrow D\) is a cofibration in \(\text{Cat}\) i.e.,

\[
a \rightarrow b
\]

and \(D\) the category with two objects

\[
a \rightarrow b
\]

In this case, the equalizer

\[
D \rightarrow D \cup_C D
\]

is \(D\) and not \(C\), since \(D \cup_C D = D\).

More over the suspension functor in \(\text{Cat}\) is trivial (equivalent to the identity functor). For all this reasons, it is not interesting to consider the category of spectra \(\text{Sp}^\text{h}(\text{Cat})\).
The goal of this section is to introduce a second new model structure on the category \textit{sCat} Quillen equivalent to the previous. The second new model structure has all the good properties (proper, cellular) and more over it is (co)tensored over the model category of simplicial sets in a compatible way with the model structure. Our main inspiration come from the technical artical \cite{2}. Roughly speaking, the authors use a new adjunction between \textit{sSet} and \textit{sSet}^2 in order to transfer the model structure to the category of bisimplicial sets, it is denoted by \textit{W}-Model structure. The class of weak equivalences are the same as in the Moerdijk model structure on \textit{sSet}^2 but there is less cofibration and more fibrations. The left adjoint functor \textit{Dec} : \textit{sSet} \to \textit{sSet}^2 used for defining \textit{W}-Model structure is cartesian i.e., \textit{Dec}(X \times Y) = \textit{Dec}(X) \times \textit{Dec}(Y). This observation is crucial for our propose. We will explain the consequence of such observation for the \textit{W}-Model structure on \textit{sCat}.

\textbf{Definition 3.1.} The Illusie functor \textit{Dec} : \textit{sSet} \to \textit{sSet}^2 is defined for all simplicial sets \(Y\) by

\[
\text{Dec}(Y)_{p,q} = Y_{p+q+1} \forall p,q.
\]

The horizontal faces are given by \(d^h_i : Y_{p+q+1} \to Y_{p+q}\), in the same way the degeneracies are \(s^h_i = s_i\). The vertical faces are given by \(d^v_j : Y_{p+1+q} \to Y_{p+q}\) and the vertical degeneracies \(s^v_j = s_{p+1+j}\).

\textbf{Lemma 3.2.} The functor \textit{Dec} has a right adjoint \textit{W} : \textit{sSet}^2 \to \textit{sSet} defined as follow:

\[
\text{W}(X)_n = \{(x_{0,n}, \ldots, x_{n,0}) \in \prod_{p=0}^{n} X_{p,n-p} | d^b_0 x_{p,n-p} = d^b_{p+1} x_{p+1,n-p-1}, 0 \leq p < n\}
\]

For the definition of degeneracies and faces of the simplicial set \textit{W}(X) we refer to \cite{2}.

\textbf{Corollary 3.3.} The functor \textit{W} commutes with directed colimites.

\textit{Proof.} Let \(\text{colim}_\lambda X\) be a directed colimit of objets in \textit{sSet}^2, the equality

\[
\text{W}(\text{colim}_\lambda X)_n = \text{colim}_\lambda \text{W}(X)_n
\]

is a consequence of the fact that a finite products commutes with directed colimites in \textit{sSet}^2. \qed

\textbf{Theorem 3.4.} \cite{2} The category of bisimplicial sets \textit{sSet}^2 admits a structure of cofibrantly generated model category, denoted by \textit{W}-structure, where a morphism \(f\) is a fibration (weak equivalence) if \textit{W}(f) is a fibration (weak equivalence) of simplicial sets. Moreover:

\begin{enumerate}
\item any Moerdijk fibration is a \textit{W}-fibration;
\item any \textit{W}-cofibration is a Moerdijk-cofibration;
\item a morphism of bisimplicial sets is a Moerdijk weak equivalence (i.e., diagonal equivalence) if and only if it is a \textit{W}-equivalence.
\end{enumerate}

Moreover, the new \textit{W}-model structure on bisimplicial sets is cofibrantly generated, where

\begin{enumerate}
\item the generating cofibrations are given by \(\text{Dec} \partial \Delta^n \to \text{Dec} \Delta^n, n \in \mathbb{N}\).
\end{enumerate}
(2) the generating acyclic cofibrations are given by $\text{Dec } \Lambda^n_i \to \text{Dec } \Delta^n$, $n \in \mathbb{N}$, $0 \leq i \leq n$.

Remark 3.5. The $\overline{W}$-structure and Moerdijk model structure on bisimplicial sets are Quillen equivalent, the equivalence is given by the functor identity. Since the functor $\text{Dec}$ is cartesian, the $\overline{W}$-model structure on simplicial sets is (co)tensored (in a compatible way) over the model category $\text{sSet}$.

Theorem 3.6. There exists a $\overline{W}$-model structure on $\text{sCat}$ equivalent to the diagonal model structure $\text{1.4}$ induced by the adjunction

\[
\begin{array}{ccc}
\text{sSet} & \xrightarrow{\pi_* \text{Dec}} & \text{sCat} \\
\overline{W}_N \text{ iso} & \xleftarrow{\pi_* \text{Dec}} & \\
\end{array}
\]

(1) A morphism $f : C_* \to D_*$ is a weak equivalence (resp. fibration) if $\overline{W}_N \text{ iso}(f)$ is a weak equivalence (resp. fibration) of simplicial sets.

(2) The generating cofibrations are given by $\pi_* \text{Dec}(\partial \Delta^n) \to \pi_* \text{Dec}(\Delta^n)$ for all $n \in \mathbb{N}$.

(3) The generating acyclic cofibrations are given by $\pi_* \text{Dec}(\Lambda^n_i) \to \pi_* \text{Dec}(\Delta^n)$ for all $n \in \mathbb{N}$ and $0 \leq i \leq n$.

Moreover, the $\overline{W}$-model structure on $\text{sCat}$ is left proper and cellular.

Proof. The generating cofibrations are given by $\pi_* \text{Dec } \partial \Delta^n \to \pi_* \text{Dec } \Delta^n$, $n \in \mathbb{N}$. The generating acyclic cofibrations are given by $\pi_* \text{Dec } \Lambda^n_i \to \pi_* \text{Dec } \Delta^n$, $n \in \mathbb{N}$, $0 \leq i \leq n$. In order to show that this choice of (acyclic) cofibrations determines a model structure, it is sufficient to show the hypothesis (2) and (4) from lemma $\text{1.2}$. The point (2) is a direct consequence of $\text{3.3}$. Let $j : \text{Dec } \Lambda^n_i \to \text{Dec } \Delta^n$ be generating acyclic cofibration in $\overline{W}$-model structure $\text{sSet}^2$. We know by $\text{3.4}$ that $j$ is an acyclic cofibration in the Moerdijk diagonal model structure on $\text{sSet}^2$. Consequently, $\pi_*(j)$ is an acyclic cofibration in the diagonal model structure on $\text{sCat}$ $\text{1.3}$. So, the pushout of $\pi_*(j)$ along a morphism $f : \pi_* \text{Dec } \Lambda^n_i \to C_*$ in $\text{sCat}$:

\[
\begin{array}{ccc}
\pi_* \text{Dec } \Lambda^n_i & \xrightarrow{f} & C_* \\
\downarrow \pi_*(j) & & \downarrow \\
\pi_* \text{Dec } \Delta^n & \xrightarrow{} & D_* \\
\end{array}
\]

is a weak diagonal equivalence i.e., $\text{diagN}_* \text{ iso } C_* \to \text{diagN}_* \text{ iso } D_*$ is a weak equivalence in $\text{sSet}$. By $\text{3.4}$ we conclude that $\overline{W}_N \text{ iso } C_* \to \overline{W}_N \text{ iso } D_*$ is an equivalence in $\text{sSet}$.

To show that $\overline{W}$-model structure on $\text{sCat}$ is left proper and cellular, we remark that cofibrations in $\overline{W}$-model structure on $\text{sCat}$ are also cofibrations in the diagonal model structure on $\text{sCat}$. Consequently, we have less cofibrations in $\overline{W}$-model structure $\text{sCat}$ than in the diagonal model structure on $\text{sCat}$, but in the same time the class of weak equivalences are the same in both model structures, it implies that $\overline{W}$-model structure on $\text{sCat}$ is left proper, cellular and Quillen equivalent to $\text{1.4}$.
Remark 3.7. We should remark at this stage that the $W$-model structure on $s\text{Cat}$ is deduced from the diagonal model structure on $s\text{Cat}$. It seems that a direct proof of $W$-model structure is quite hard. The following section we will see why it is better to consider $W$-structure than the diagonal one.

Remark 3.8. The diagonal model structure (resp. the $W$-model structure) on $s\text{Cat}$ can be restricted in a natural way to the diagonal model structure (resp. $W$-model structure) on $s\text{Grp}$, the category of simplicial groupoids.

4. Pointed model structure $s\text{Cat}_*$

The main goal of this section is to define the suspension and loop functor in the model category $s\text{Cat}$. In order to construct such functors we need a pointed model version of $s\text{Cat}$. We denote the pointed category by $s\text{Cat}_*$ or by $\ast \downarrow s\text{Cat}$ (§, chapter 6).

Definition 4.1. A pointed category $C$ is equipped with a functor $\ast \rightarrow C$ where $\ast$ is the terminal object in $s\text{Cat}$.

Recall the the tensorization of $\text{Cat}$ by $s\text{Set}$ is defined by

$$X_\ast \otimes C = \pi X_\ast \times C$$

similarly, the cotensorization is given by

$$C^{X_\ast} = \text{HOM}_{\text{Cat}}(\pi X_\ast, C)$$

We construct a (co)tensorization of $s\text{Cat}_*$ by $s\text{Set}_*$ following the same procedures as before but in more general context. Suppose that we have an adjunction between $s\text{Set}$ and $s\text{Cat}$ such that the left adjoint is cartesian $\rho : s\text{Set} \rightarrow s\text{Cat}$ i.e.,

$$\rho(X_\ast) \times \rho(Y_\ast) = \rho(X_\ast \times Y_\ast).$$

The tensorization is defined by $C_\ast \otimes_{\rho} X_\ast = C \times \rho X_\ast$ and the cotensorization by $C^{X_\ast} = \text{HOM}_{s\text{Cat}}(\rho X_\ast, C_\ast)$.

Definition 4.2. Let $C_\ast$ an object of $s\text{Cat}_*$. In order to construct the tensorization,

$$- \otimes - : s\text{Cat}_* \times s\text{Set}_* \rightarrow s\text{Cat}_*$$

we start by defining the tensor product with $\Delta^n$ then for all simplicial sets $s\text{Set}$ by left Kan extension. In particular, $C_\ast \otimes \Delta^n$ is given by the pushout:

$$\begin{array}{ccc}
\ast \otimes_{\rho} \Delta^n & \rightarrow & C_\ast \otimes_{\rho} \Delta^n \\
\downarrow & & \downarrow \\
\ast & \rightarrow & C_\ast \otimes_{\rho} \Delta^n.
\end{array}$$

Definition 4.3. The smash product $- \wedge_{\rho} - : s\text{Set}_* \times s\text{Cat}_* \rightarrow s\text{Cat}_*$ is defined first for $\Delta^n$ by the formula

$$C_\ast \wedge_{\rho} \Delta^n = C_\ast \odot_{\rho} \Delta^n$$

and then extended to $s\text{Set}_*$ by left Kan extension.

Lemma 4.4. The functor $- \odot_{\rho} X_\ast : s\text{Cat}_* \rightarrow s\text{Cat}_*$ admits a right adjoint which is denoted by $(-)^{X_\ast} : s\text{Cat}_* \rightarrow s\text{Cat}_*$. 

Proof. First of all, we construct the adjoint for $- \odot \Delta^n$. The functor
\[ \text{HOM}_{\text{sCat}}(\rho \Delta^n, -) : \text{sCat} \to \text{sCat} \]
which is the right adjoint to the cartesian product for $\text{sCat}$, it sends a pointed category $C$ to a pointed category $\text{HOM}_{\text{sCat}}(\rho \Delta^n, C)$, where the point is given by the constant functor $0 : \rho \Delta^n \to C$. We have to verify that it is an adjoint of $- \odot \rho \Delta^n$ in $\text{sCat}$. Giving a (simplicial) functor $f : C \odot \rho \Delta^n \to D$ is equivalent to give a functor $\tilde{f} : C \times \rho \Delta^n \to D$ which sends the sub category $\ast \odot \rho \Delta^n$ to the base point in $D$, by the same way, it is equivalent to give a pointed functor $g : C \to \text{HOM}_{\text{sCat}}(\rho \Delta^n, D) := D \Delta^n$. So, in order to prove the adjunction for any simplicial set $X$, we remark that
\[ C \odot \rho (\text{colim} \Delta^n \to X) = \text{colim} \Delta^n \to X((C \odot \rho \Delta^n)). \]
\[ \square \]

Taking our inspiration from $\text{sSet}$, we construct a new model structure on $\text{sCat}$ using the adjunction induced by the forgetful functor and left adjoint which adds a base point. We will show that the new model structure on $\text{sCat}$ is (co)tensored over the model category of simplicial sets $\text{sSet}$. The adjunction
\[ \text{sCat} \xrightarrow{(-)_{+}} U \xleftarrow{} \text{sCat}_\ast \]
defines a model structure on $\text{sCat}_\ast$, the weak equivalences and fibrations are simply those in the underlying model category $\text{sCat}$. For more details see [6].

In this paragraph, we show that for any pointed simplicial set $X$, the functors $- \wedge X$ and $(-)^X$ form a Quillen pair. First of all, that a simplicial pointed set $p : \Delta^0 \to X$ by the following pushout diagram:

\[ \begin{array}{ccc}
\Delta^0 & \xrightarrow{p} & X \\
\downarrow & & \downarrow \\
\ast & \to & X
\end{array} \]

**Theorem 4.5.** If $X$ is a pointed simplicial set, then the functor
\[ - \wedge X : \text{sCat} \to \text{sCat}_\ast \]
is a left Quillen functor, where $\text{sCat}$ is equipped with $\overline{W}$-model structure. Moreover, the functor $- \wedge X$ has a right Quillen adjoint.

**Proof.** First, we simplify our notation, a simplicial set $X$ will be denoted by $X$. Let $C$ an object of $\text{sCat}$, then $C_\ast \wedge X_+ = (C_\ast \odot X)_+$. In order to show that $X \wedge -$ is a left Quillen functor, it is sufficient to show that the image of generating (acyclic) of $\text{sCat}$ are (acyclic) cofibrations. We start with the case where $X$ has
a disjoint base point. Consider the following pushout diagram:

\[
\begin{array}{c}
\pi_* \text{Dec}\Delta^0_+ \wedge \pi_* \text{Dec}A_+ \rightarrow \pi_* \text{Dec}X_+ \wedge \pi_* \text{Dec}A_+ \\
\pi_* \text{Dec}\Delta^0_+ \wedge \pi_* \text{Dec}B_+ \rightarrow P_+ \\
\pi_* \text{Dec}X_+ \wedge \pi_* \text{Dec}B_+
\end{array}
\]

where \(A \rightarrow B\) is an generating (acyclic) cofibration in \(\text{sSet}\). The previous diagram is equivalent to the pushout diagram:

\[
\begin{array}{c}
\pi_* \text{Dec}(\Delta^0 \times A)_+ \rightarrow \pi_* \text{Dec}(X \times A)_+ \\
\pi_* \text{Dec}(\Delta^0 \times B)_+ \rightarrow P_* \\
\pi_* \text{Dec}(X \times B)_+
\end{array}
\]

We have \(P_* = \pi_* \text{Dec}(\Delta^0 \times B \uplus \Delta^0 \times A \times X \times A)\), since \(\pi_* \text{Dec}\) and \((-)_+\) commutes with colimits, and the unique morphism \(\pi_* \text{Dec}(\Delta^0 \times B \uplus \Delta^0 \times A \times X \times A) \rightarrow \pi_* \text{Dec}(X \times B)\) is obviously an (acyclic) cofibration in \(\text{sCat}_*\) since \(\text{sSet}\) is monoidal model category, and \(\pi_*\), \((-)_+, \text{Dec}\) are left Quillen functors. Now, we have to show that \(\pi_* \text{Dec}(X \wedge A_+) \rightarrow \pi_* \text{Dec}(X \wedge B_+)\) is a cofibration (acyclic cofibration) in \(\text{sCat}_*\) i.e., has a lifting property with respect to the acyclic fibrations (resp. fibrations).

\[
C_* \rightarrow D_*
\]

The following diagram summarize the situation:

\[
\begin{array}{c}
\pi_* \text{Dec}(\Delta^0 \times A)_+ \rightarrow \pi_* \text{Dec}(X \times A)_+ \\
\pi_* \text{Dec}(\Delta^0 \times B)_+ \rightarrow P_* \\
\pi_* \text{Dec}(X \times B)_+ \rightarrow \pi_* \text{Dec}(X \wedge A_+) \rightarrow C_+ \\
\pi_* \text{Dec}(X \wedge B_+) \rightarrow \pi_* \text{Dec}(X \wedge B_+) \rightarrow D_*
\end{array}
\]

The morphism \((0) : \pi_* \text{Dec}(\Delta^0 \times B)_+ \rightarrow C_*\) is the obvious morphism which sends everything to the base point of \(C\). The arrow \((1) : P_* \rightarrow C_*\) is constructed by the universal property of the pushout

\[
\begin{array}{c}
\pi_* \text{Dec}\Delta^0_+ \wedge \pi_* \text{Dec}A_+ \rightarrow \pi_* \text{Dec}X_+ \wedge \pi_* \text{Dec}A_+ \\
\pi_* \text{Dec}\Delta^0_+ \wedge \pi_* \text{Dec}B_+ \rightarrow P_* \\
\pi_* \text{Dec}\Delta^0_+ \wedge \pi_* \text{Dec}B_+ \rightarrow C_*
\end{array}
\]

Than, the arrow \((2)\) is a lifting of the (acyclic) cofibration \(f\).
Finally, we construct the third arrow (3) \( \pi_\ast \text{Dec}(X \wedge B_+) \rightarrow C_\ast \) which makes the diagram commutes by the universal property of colimits. In fact, the following diagram is a pushout in \( \text{sCat} \).

\[
\begin{array}{ccc}
\pi_\ast \text{Dec}(\Delta^0 \times B)_+ & \rightarrow & \pi_\ast \text{Dec}(X \times B)_+ \\
\downarrow & & \downarrow \\
\ast & \rightarrow & \pi_\ast \text{Dec}(X \wedge B_+)_+
\end{array}
\]

because the functor \( \pi_\ast \text{Dec} \) commutes with colimits.

we conclude that \( X_\ast \wedge - \) is a left Quillen functor, consequently \( (-)^X \) is a right Quillen functor. \( \square \)

5. Spectra \( \text{Sp}^N(\text{sCat}_\ast) \) and Algebraic K-theory

This section is the outcome of this article. We define categories which look like Waldhausen categories and we will suggest a new definition of algebraic K-theory for pointed simplicial categories. In what follow, \( \mathcal{M} \) is a cofibrantly generated model category, cellular and left proper, equipped with a left Quillen endofunctor \( T : \mathcal{M} \rightarrow \mathcal{M} \) with a corresponding right Quillen adjoint \( U \).

**Definition 5.1.** Objects of \( \text{Sp}^N(\mathcal{M}, T) \) are sequences \( \mathcal{X} = \{X_0, X_1, \ldots, X_n, \ldots\} \) of objects in \( \mathcal{M} \), equipped with sequence of compatible structural morphisms \( \sigma^n_X : TX_n \rightarrow X_{n+1} \) for all \( n \in \mathbb{N} \). Morphisms in \( \text{Sp}^N(\mathcal{M}, T) \) between \( \mathcal{X} = \{X_0, X_1, \ldots, X_n, \ldots\} \) and \( \mathcal{Y} = \{Y_0, Y_1, \ldots, Y_n, \ldots\} \) are degree wise morphisms in \( \mathcal{M} \) which commutes with the structural morphisms i.e., we have commutative diagrams for each natural number \( n \):

\[
\begin{array}{ccc}
TX_n & \xrightarrow{Tf_n} & TY_n \\
\downarrow{\sigma^n_X} & & \downarrow{\sigma^n_Y} \\
X_{n+1} & \xrightarrow{f_{n+1}} & Y_{n+1}.
\end{array}
\]

**Definition 5.2.** A U-spectra in \( \text{Sp}^N(\mathcal{M}, T) \) is a sequence \( \mathcal{X} = \{X_0, X_1, \ldots, X_n, \ldots\} \) such that \( X_n \) is fibrant in \( \mathcal{M} \) for all \( n \) and the adjoint map of \( \sigma_X : TX_n \rightarrow X_{n+1} \) i.e., \( \tau_X : X_n \rightarrow UX_{n+1} \) is a weak equivalence in \( \mathcal{M} \) for all \( n \).

**Theorem 5.3.** There exists a stable model structure on the category of spectra \( \text{Sp}^N(\mathcal{M}, T) \) where fibrant objects are U-spectres.

**Proof.** See [7] Theorem 3.4. \( \square \)

In the model structure \( \text{Sp}^N(\mathcal{M}, T) \), the left Quillen functor \( T : \mathcal{M} \rightarrow \mathcal{M} \) is extended to a left Quillen functor \( T : \text{Sp}^N(\mathcal{M}, T) \rightarrow \text{Sp}^N(\mathcal{M}, T) \) which admits a right adjoint denotes by \( s_- \) such that \( (s_-X)_n = X_{n+1} \) for \( n > 0 \). The adjunction \( (T, s_-) \) is a Quillen equivalence (cf [7] Theorem 3.9). We should remark that the derived functor \( LT \) became an invertible endofunctor in the homotopy category \( \text{HoSp}^N(\mathcal{M}, T) \).
We have also a Quillen adjunction between $\mathcal{M}$ and $\text{Sp}^N(\mathcal{M}, T)$ given by:

$$
\mathcal{M} \xrightarrow{T^\infty} \text{Sp}^N(\mathcal{M}, T)
$$

where $T^\infty (X) = \{X, TX, TTX, \ldots \}$ and $\sigma^n_X = \text{id}_{T^{n+1} X}$. The functor $(-)_0$ associates to each spectra $X = \{X_0, X_1, \ldots, X_n, \ldots \}$ the object $X_0$.

**Theorem 5.4.** There is a cofibrantly generated stable model category structure on $\text{Sp}^N(s\text{Cat}_*, \Sigma)$.

**Proof.** The category $s\text{Cat}_*$ verify the hypothesis of [5.3] (cellular, left proper, cofibrantly generated), and the functor $\Sigma = - \wedge S^1 : s\text{Cat}_* \to s\text{Cat}_*$, where $S^1$ is a simplicial model for a circle, is a left Quillen functor [4.5] with a right adjoint denoted by $\Omega$. We conclude the stable model structure on $\text{Sp}^N(s\text{Cat}_*, \Sigma)$ exists. □

**Definition 5.5.** A simplicial category is called a weak complete Wladhausen category if it is equivalent to a 0-object of some $\Omega$-spectre in the stable category of spectra $\text{Sp}^N(s\text{Cat}_*, \Sigma)$.

In some sense, a weak Wladhausen category is an infinite loop space in the category of spectra $s\text{Cat}_*$. In order to justify this definition we compute the mapping space $\text{map}_*$ of the model category $\text{Sp}^N(s\text{Cat}_*, \Sigma)$. The following equivalences are a direct consequence of 5.6.

**Theorem 5.6.** ([3], Theorem 2.12.) Let the following Quillen adjunction between two model categories:

$$
\mathcal{C} \xleftarrow{G} \mathcal{M}
$$

then we have a natural isomorphism

$$
\text{map}_\mathcal{C}(a, RFb) \to \text{map}_\mathcal{M}(LGa, b)
$$

in the category $\text{Ho}(s\text{Set})$.

A consequence of theorem 5.6 in the case of $s\text{Cat}$ where we consider the Quillen adjunction between $s\text{Set}$, $s\text{Set}^2$ and $s\text{Cat}$ gives us the following result:

**Corollary 5.7.** Let $C_\bullet$ be a fibrant object in $s\text{Cat}$ and $X \in s\text{Set}$. We have a natural isomorphism $\text{Ho}(s\text{Set})$:

$$
\text{map}_{s\text{Cat}}(\pi d_* X, C_\bullet) \to \text{Map}(X, \text{diag}N_\bullet \text{iso}C_\bullet),
$$

where $\text{Map}$ is the right adjoint to the cartesian product in $s\text{Set}$.

**Proof.** The isomorphism $\text{map}_{s\text{Cat}}(\pi d_* X, C_\bullet) \to \text{map}_{s\text{Set}}(X, \text{diag}N_\bullet \text{iso}C_\bullet)$ is a direct consequence of 5.6. Since $s\text{Set}$ is a simplicial model category we have that

$$
\text{map}_{s\text{Set}}(X, \text{diag}N_\bullet \text{iso}C_\bullet) \simeq \text{Map}(X, \text{diag}N_\bullet \text{iso}C_\bullet)
$$
in $\text{Ho}(s\text{Set})$. □
There is a natural transformation between diag and the functor \( W \) which is a weak equivalence i.e., \( \text{diag}(X) \to W(X) \) is a weak equivalence in \( \text{sSet} \), for any simplicial set \( X \).

Let \( D^\bullet_\ast = \{ D^0_\ast, D^1_\ast, \ldots, D^n_\ast, \ldots \} \) be an \( \Omega \)-spectra in \( \text{Sp}^\Omega_\ast(\text{sCat}_\ast, \Sigma) \). We have a the following corollaries:

**Corollary 5.8.** Let \( C^\bullet \) be a simplicial (pointed) category in \( \text{sCat} \) equipped with the \( \overline{W} \)-model structure. The adjunction

\[
\text{sSet} \xrightarrow{\pi_\ast} \text{sCat}
\]

\[
\text{diag} \overset{\text{iso}}{\Rightarrow} \text{sCat}.
\]

gives us the isomorphism \( \text{map}_{\text{sCat}}(*, C^\bullet) \sim \text{diag} \text{iso} C^\bullet \) in \( \text{Ho}(\text{sSet}) \).

**Corollary 5.9.** If we denote by \( S^0 \) the constant simplicial category \(* \sqcup *\), then the adjunction:

\[
\text{sCat} \xrightarrow{(-)^+} \text{sCat}^\ast
\]

\[
\text{diag} \overset{\text{iso}}{\Rightarrow} \text{sCat}^\ast
\]

gives us the isomorphism \( \text{map}_{\text{sCat}}(S^0, C^\bullet) \sim \text{map}_{\text{sCat}}(*, C^\bullet) \sim \text{diag} \text{iso} C^\bullet \) in \( \text{Ho}(\text{sSet}) \).

**Corollary 5.10.** The adjunction

\[
\text{sCat} \xrightarrow{\Sigma^\infty} \text{Sp}^\Omega(\text{sCat}_\ast, \Sigma)
\]

\[
\text{diag} \overset{\text{iso}}{\Rightarrow} \text{Sp}^\Omega(\text{sCat}_\ast, \Sigma)
\]

gives us the isomorphism \( \text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(\Sigma^\infty S^0, D^\bullet_\ast) \sim \text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(S^0, D^\bullet_\ast) \sim \text{diag} \text{iso} D^\bullet_\ast \),

**Corollary 5.11.** The adjunction

\[
\text{Sp}^\Omega(\text{sCat}_\ast, \Sigma) \xrightarrow{\Sigma} \text{Sp}^\Omega(\text{sCat}_\ast, \Sigma)
\]

induces an isomorphism

\[
\text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(\Sigma^\infty S^0, D^\bullet_\ast) \sim \text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(\Sigma^\infty s^\ast, D^\bullet_\ast) \sim \text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(S^0, D^\bullet_\ast) \sim \text{diag} \text{iso} D^\bullet_\ast
\]

and more generally

\[
\text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(\Sigma^\infty S^0, D^\bullet_\ast) \sim \text{map}_{\text{Sp}^\Omega(\text{sCat}_\ast)}(S^0, D^\bullet_\ast) \sim \text{diag} \text{iso} D^\bullet_\ast
\]

**Remark 5.12.** Let \( S^n \) be a simplicial model for the sphere of dimension \( n \), then \( \pi_\ast d_\ast S^n \) is a simplicial category and \( \Sigma(\pi_\ast d_\ast S^n) \sim \pi_\ast d_\ast S^{n+1} \).

By definition of \( \text{map}_{\text{sCat}_\ast} \) and the fact that \( D^\bullet_\ast \to \Omega D^\bullet_{n+1} \) is an equivalence in \( \text{sCat}_\ast \) between fibrant objects, we deduce the following corollary.

**Corollary 5.13.** Using the precedent Quillen adjunctions and \( 5.6 \), we have the following isomorphisms in \( \text{Ho}(\text{sSet}) \):

1. \( \text{map}_{\text{sCat}}(\Sigma S^0, D^\bullet_{n+1}) \sim \text{map}_{\text{sCat}}(S^0, \Omega D^\bullet_{n+1}) \sim \text{diag} \text{iso} D^\bullet_{n+1} \).
2. \( \text{map}_{\text{sCat}}(\Sigma S^0, D^\bullet_1) \sim \text{map}_{\text{sCat}}(\pi_\ast d_\ast S^1, D^\bullet_1) \sim \Omega \text{diag} \text{iso} D^\bullet_1 \).
3. \( \text{map}_{\text{sCat}}(\Sigma S^0, D^\bullet_1) \sim \text{map}_{\text{sCat}}(S^0, \Omega D^\bullet_{n+1}) \sim \text{map}_{\text{sCat}}(S^0, D^\bullet_0) \sim \text{diag} \text{iso} D^\bullet_0 \).
5.1. **Algebraic $\mathbb{K}$-theory.** As before, we suppose that $D^\bullet = \{D^0, D^1, \ldots \}$ is an $\Omega$-spectra in $\text{Sp}^N(s\text{Cat}_*, \Sigma)$. In general the sequence of simplicial sets

$\{\text{map}_{s\text{Cat}_*}(S^0, D^0), \text{map}_{s\text{Cat}_*}(S^0, D^1), \ldots \}$

does not form a spectra in $\text{Sp}^N(s\text{Set}_*, \Sigma)$. This sequence is not an element of $\text{Sp}^N(s\text{Set}_*, \Sigma)$ but it has the property of an $\Omega$-spectra, i.e.,

$\text{map}_{s\text{Cat}_*}(S^0, D^n) \simeq \Omega \text{map}_{s\text{Cat}_*}(S^0, D^{n+1}), \forall n \in \mathbb{N}$.

In some sense, an $\Omega$-spectra $D^\bullet$ has the property that $D^{n+1}$ is a model for the Waldhausen $S_\bullet$-construction for $D^n$, i.e., $D^{n+1}$ is a model for $S_\bullet D^n$. Or equivalently, $D^{n+1}$ is a categorical delooping for $D^n$.

**Definition 5.14.** Let $C^\bullet$ be a simplicial category (i.e., an objet of $s\text{Cat}_*$) which is a weak complete Waldhausen category \[5.5\] we define the algebraic $\mathbb{K}$-theory of $C^\bullet$ by the simplicial set $\text{map}_{s\text{Cat}_*}(S^0, C^\bullet)$, so $K_i(C^\bullet) = \pi_i \text{map}_{s\text{Cat}_*}(S^0, C^\bullet)$.

**Appendix A.**

**Lemma A.1.** Let $\mathcal{C} \xrightarrow{G} \mathcal{D}$ be an adjunction, such that $F$ commutes with directed colimits. If $C \in \mathcal{C}$ is a small object for a certain ordinal $\beta$, then $G(C)$ is small in $\mathcal{D}$.

**Proof.** Suppose that we have a directed colimit $\text{colim}_{\alpha < \beta} T_\alpha$ in $\mathcal{D}$. We have the following sequence of isomorphisms

$\text{hom}_\mathcal{D}(G(C), \text{colim}_{\alpha < \beta} T_\alpha) \simeq \text{hom}_\mathcal{C}(C, F\text{colim}_{\alpha < \beta} T_\alpha)$

$\simeq \text{hom}_\mathcal{C}(C, \text{colim}_{\alpha < \beta} F(T_\alpha))$

$\simeq \text{colim}_{\alpha < \beta} \text{hom}_\mathcal{C}(C, F(T_\alpha))$

$\simeq \text{colim}_{\alpha < \beta} \text{hom}_\mathcal{D}(G(C), T_\alpha)$

The sequence isomorphism, is a consequence of the fact that $F$ commutes with directed colimits. The rest of isomorphisms are obvious because $C$ is $\beta$-small by definition.

**Lemma A.2.** In Moerdijk’s model category on bisimplicial sets, domains and codomains of generating (acyclic) cofibrations I (J) are small.

**Proof.** The generating (acyclic) cofibration in $s\text{Set}^2$ are the image of generating (acyclic) cofibration via the fonctor $d_*$ of generating (acyclic) cofibration $s\text{Set}$.

$s\text{Set} \xrightarrow{d_*} s\text{Set}^2$

We recall that diag admits also a right adjoint denoted by $d^*$, so diag commutes with colimits. Moreover objects in $s\text{Set}$ are small for a certain ordinal. Let $A$ be a (co)domain of a generating acyclic cofibration in $s\text{Set}$, then $d_* A$ is small in $s\text{Set}^2$ by the lemma [A.1]

**Lemma A.3.** The functor $\text{diag}_N \text{iso} : s\text{Cat} \to s\text{Set}$ commutes with directed colimits.
Proof. Let $\text{colim}_\lambda C^\lambda$ be a directed colimit in $\mathbf{sCat}$, for a certain ordinal $\lambda$.

\[
\left(\text{diag}\mathbb{N}\text{iso}(\text{colim}_\lambda C^\lambda)\right)_n = \text{hom}_{\mathbf{sSet}}(\Delta^n, \text{diag}\mathbb{N}\text{iso}(\text{colim}_\lambda C^\lambda)) \\
= \text{hom}_{\mathbf{sCat}}(\pi_n d_\ast(\Delta^n), \text{colim}_\lambda C^\lambda_n) \\
= \text{hom}_{\mathbf{sCat}}(\pi_n(\sqcup\Delta^n \Delta^n), \text{colim}_\lambda C^\lambda_n) \\
= \text{hom}_{\mathbf{sCat}}(\pi(\Delta^n), \text{colim}_\lambda C^\lambda) \\
= \text{hom}_{\mathbf{Cat}}(\pi\Delta^n, \text{colim}_\lambda C^\lambda_n) \\
= \text{colim}_\lambda \text{hom}_{\mathbf{Cat}}(\pi\Delta^n, C^\lambda_n) \\
= \text{colim}_\lambda \text{hom}_{\mathbf{sCat}}(\pi_n d_\ast(\Delta^n), C^\lambda_n) \\
= \text{colim}_\lambda \text{hom}_{\mathbf{sSet}}(\Delta^n, \text{diag}\mathbb{N}\text{iso}C^\lambda_n) \\
= \text{colim}_\lambda \left(\text{diag}\mathbb{N}\text{iso}C^\lambda_n\right)_n.
\]

All the isomorphisms are consequence of adjunctions. The fifth isomorphism is due to the fact that $\pi\Delta^n$ is a small object in $\mathbf{Cat}$. \qed

Lemma A.4. The domains and codomains of generating (acyclic) cofibrations in $\mathbf{sCat}$ are small.

Proof. It is a consequence of [A.1, A.3] and the fact that all objects in $\mathbf{sSet}$ are small for a certain ordinal. \qed
