Abstract

Recently, power systems are confronting a lot of challenges. Increasing the dependence on renewable energy sources especially wind energy and its impact on the stability of electrical systems are the most important challenges. Flexible alternating current transmission systems (FACTS) can be used to improve the relationship between wind farms and electrical grids. The performance of these FACTS depends on the parameters of its control system. These parameters can be tuned using modern methods like Artificial Neural Network (ANN). In this paper, ANN is used to improve the performance of static synchronous series compensator (SSSC) integrated into combined wind farm (CWF). This CWF is composed of squirrel cage induction generators (SCIG) and doubly fed induction generators (DFIG) wind turbines. This wind farm is collecting the advantage of SCIG and DFIG wind turbines. To view out the motivation of this paper, a comparison is done among the performances of combined wind farm (CWF) with ANN-SSSC, CWF with ordinary SSSC and CWF with SSSC tune by Multi-objective genetic algorithm (MOGA SSSC). The root mean square Error (RMSE) is used to evaluate the results. The results illustrate that the performance of CWF can be improved using SSSC adjusted by ANN.

Keywords

Squirrel Cage Induction Generator (SCIG), Doubly Fed Induction Generator (DFIG), Combined Wind Farm (CWF), Static Synchronous Series Compensator (SSSC), Artificial Neural Network (ANN).

I. Introduction

Renewable energy is an important source for the power generation. Solar energy, and wind energy are the most famous forms of this technology. Wind energy plays an important role in producing electric power in all the world so that its injection on the grid represents a wide range of studies. This injection depends on the induction generator of the wind turbines. There are two types of induction generator, first type is squirrel cage induction generators (SCIG) which are suitable to fixed speed wind turbines and second type is doubly fed induction generators (DFIG) that are used with variable speed wind turbines. The stability of wind farms is affected by the exchange in the reactive power between the interconnected grid and the wind farms. The compensation devices of the reactive power consider a fundamental element in SCIG wind turbines (SCIG-WT). The flexible alternating current transmission systems (FACTS) were used to damp power oscillation and, enhance power stability. In Ref. [1] a dual STATCOM had been used to damp power oscillations. Tuning parameters of SSSC had been proposed in [2] to damp power oscillations. In Ref [3] a unified power flow controller has been used to damp power oscillations between two areas. The SSSC used to damp power oscillation, enhance power stability and control the power flow of DFIG-WF is studied in [4]-[5]. The effect of FACTS such as Static VAR Compensator (SVC), Static Synchronous Compensator (STATCM) and SSSC on the performance of wind farms were studied in [6]-[10]. The impact of SSSC on the performance of different types of wind farms had been discussed in [11].

The main advantage of Artificial intelligence (AI) is solving complex problems in less time and with high precision, such as using optimization methods to solve the complex control problem. Also, AI can easily predict and take the correct decisions with little margin of error. It can be used for predicting the change in wind speed and its impact on stability of power system. In this paper, AI has been used to predict and determine the optimal value of the control gains of SSSC which can enhance the performance of CWF. On other side, AI represents high technology so that it is storage costly. In last years, Artificial Intelligence (AI) has been used extensively in improving the performance of FACTS and enhancing the performance of wind farms interconnected grid. A genetic algorithm has been implemented to tune different type of FACTS interconnected wind farms and photovoltaic solar plant in [12]. In ref [13] [14] multi-objective genetic algorithm is used to improve the performance of DFIG. Also, multi-objective genetic algorithm is used to find the optimal gains of SSSC in [15]. Adaptive-network-based fuzzy inference system (ANFIS), ANN and genetic algorithm are proposed in [16] to improve the reactive power control of STATCOM. The whale optimization algorithm, genetic algorithm and ANN were used in [17] to determine the optimal parameters of STATCOM integrated with CWF. In Ref [18] particle swarm optimization is used to tune and damp power system oscillation of DFIG wind farms integrated with SSSC. A new control strategy based on ANFIS is proposed in [19] to improve the performance of DFIG wind farm integrated with SSSC.
This paper aims to improve the performance of CWF which is based on SCIG and DFIG using SSSC controlled by ANN (ANN-SSSC). Also, in this paper the control parameters which had been investigated in [15] are used for implementing ANN. Moreover, a comparison is done between the performances of CWF with ordinary SSSC, CWF associated with SSSC tuned by multi-objective genetic algorithm (SSSC MOGA) investigated in [15] and CWF associated with proposed ANN-SSSC during three phase-faults.

The rest of the paper is organized as follows. Section II presents a brief summary of ANN. Section III presents modelling of wind turbines. Section IV explains the construction, operation and control system of SSSC. Section V introduces the proposed ANN control, which is applied to SSSC. The last two sections present the results and conclusion.

II. Artificial Neural Network (ANN)

The artificial neural network is a modest simulation of the effect, form and content of the neural network found in the human brain. It consists of nodes called neurons and connected together by bonds called weights. Each set of neurons forms a single layer; the ANN is composed of different types of layers. From Fig. 1, it can be observed that it consists of input layer, hidden layer (processing element) and output layer. The hidden layer could be single layer or multi-layers. The input signal is passed from input layer to the output layer through the hidden layer. The input is transferred to the neurons through weight matrix W. The output can be given by [20]:

$$Y_{out} = \sum_{j=1}^{n} x_i w_{ij}$$

(1)

Where $Y_{out}$ represents the output of ANN, $x_i$ is input signal which starts from 1 to n inputs and $w_{ij}$ represents the synaptic weights between neurons.

III. Modeling of Wind Turbines

The mathematical model of wind turbines was discussed in several articles on wind energy. Fig. 2 shows the equivalent circuit of induction generator. The direct and quadratic (d-q) illustration of IG with respect to the synchronous frame can be illustrated as flows [21] [22]:

$$\begin{align*}
\psi_{ds} &= p\psi_{ds} - \omega_s \varphi_{qs} + R_s i_{ds} \\
\psi_{qs} &= p\psi_{qs} - \omega_s \varphi_{ds} + R_s i_{qs}
\end{align*}$$

(2)

$$\begin{align*}
\varphi_{dr} &= p\varphi_{dr} - \omega_s \varphi_{qr} + R_r i_{dr} \\
\varphi_{qr} &= p\varphi_{qr} - \omega_s \varphi_{dr} + R_r i_{qr}
\end{align*}$$

(3)

$$\begin{bmatrix}
\dot{i}_{ds} \\
\dot{i}_{qs} \\
\dot{i}_{dr} \\
\dot{i}_{qr}
\end{bmatrix} =
\begin{bmatrix}
(L_{ds} + L_m) & 0 & -L_m & 0 \\
0 & (L_{ds} + L_m) & 0 & -L_m \\
-L_m & 0 & (L_{dr} + L_m) & 0 \\
0 & -L_m & 0 & (L_{dq} + L_m)
\end{bmatrix}
\begin{bmatrix}
i_{ds} \\
i_{qs} \\
i_{dr} \\
i_{dq}
\end{bmatrix} +
\begin{bmatrix}
0 \\
0 \\
L_m \\
0
\end{bmatrix} \varphi_{dr} +
\begin{bmatrix}
0 \\
0 \\
0 \\
0
\end{bmatrix} \varphi_{qr}$$

(4)

$$
\begin{bmatrix}
i_{ds} \\
i_{qs} \\
i_{dr} \\
i_{dq}
\end{bmatrix} =
\frac{1}{(L_{ds}+L_m)\epsilon_0+L_m}\begin{bmatrix}
(L_{dr}+L_m) & 0 & -L_m & 0 \\
0 & (L_{ds}+L_m) & 0 & -L_m \\
-L_m & 0 & (L_{dr}+L_m) & 0 \\
0 & -L_m & 0 & (L_{ds}+L_m)
\end{bmatrix}
\begin{bmatrix}
\psi_{ds} \\
\psi_{qs} \\
\psi_{dr} \\
\psi_{qr}
\end{bmatrix}$$

(5)
The extracted power from the wind by wind farms is given by:

\[ P_{\text{wt}} = \frac{1}{2} \rho A v^3 C_p \]

\[ C_p = 0.517 \left( \frac{116}{\lambda_i} - 0.4\beta - 5 \right) e^{-\frac{\lambda_i}{\lambda_i + 0.08\beta}} + 0.0068\lambda \]

\[ \lambda_i = \frac{1}{116} \left( \frac{1}{\lambda_i + 0.08\beta} - \frac{0.035}{\beta^2 + 1} \right) \]

Where, \( v \) is the wind speed, \( \rho \) is the air density, \( C_p \) is the power coefficient, \( A \) is the area swept by the turbine blades, \( \lambda_i \) is the blade length or rotor radius, \( \omega_r \) is the rotor speed and it is equal to 1.22Kg/m3. \( \lambda \) is a function on the pitch angle \( \beta \) and the tip speed ratio \( \lambda \).

The electrical torque of SCIG and DFIG is given by:

\[ T_e = \frac{3P}{2} \left( i_q s \phi_d - i_d s \phi_q s \right) \]

\[ T_e = \frac{3P}{2} \left( i_q s \phi_d - i_d s \phi_q s \right) \]

The pitch angle control method is used to control the rotor speed of wind turbine in order to keep the output power inside permissible limits. Fig. 4 illustrates a schematic diagram of pitch angle control system [23].

**IV. Static Synchronous Series Compensator (SSSC)**

The Static Synchronous Series Compensator (SSSC) belongs to the series devices of FACTS controller [23]. It is a series connected with the transmission line so that it injects a series voltage which is in phase quadrature with the line current. The block diagram of SSSC and its equivalent circuit are shown in Fig. 5. As shown in Fig. 5. The SSSC is connected in series with the transmission line of an electrical grid by a coupling transformer.
V. APPLYING THE ANN METHOD

In this work the ANN is based on multi-layer feed-forward network. The multi-layer is divided into three layers: input, hidden, and output layer. The neural fitting tool (NFTOOL) and the sample range are based on the value of control parameters of SSSC tuned by multi-objective genetic algorithm (SSSC MOGA) investigated in [15]. Also, Fig. 7 illustrates that the input signal is the change in voltage at the point of connection and the output layer represents the control parameters of SSSC (AC voltage regulator (Kp-vac and Ki-vac) and DC voltage regulator (Kp-vdc and Ki-vdc)). In this work, Levenberg-Marquardt algorithm is used for training the value of control parameters of SSSC tuned by multi-objective genetic algorithm (SSSC MOGA) investigated in [15].

The neural fitting tool (NFTOOL) is composed of sets of processes: training, validation, and testing. The application divides input and target into three groups as follows: 70% is applied for training, 15% is applied to validate, and 15% is applied to test. Table I shows the parameters of NFTOOL and illustrates the mean square error (MSE) and regression value (R) of training, validation, and testing.

| Process   | Selected percentage | Number of samples | MES           | R value     |
|-----------|---------------------|-------------------|---------------|-------------|
| training  | 70%                 | 6385              | 4.790e-5      | 1.859e-1    |
| validation| 30%                 | 1362              | 4.8334e-5     | 1.909e-1    |
| testing   | 30%                 | 1362              | 4.8614e-5     | 1.826e-1    |

Type of algorithm: Levenberg-Marquardt and multi-objective genetic algorithm investigated in [15].

In this study NFTOOL is a feedforward network with input, output, and multi-layers. Fig. 8 (a) illustrates the neural network size. Fig. 8 (b) illustrates training, validation, and testing samples. Fig. 8 (c) illustrates results of training operation. Fig. 9 illustrates best validation performance. Fig. 10 illustrates the ANN controller of DC and AC voltage regulators.
Fig. 9. The performance's convergence of the studied system with ANN.

Fig. 10. ANN controller of DC and AC voltage regulators.

VI. STUDIED SYSTEM DESCRIPTION

The studied system contains six wind turbines, each one produces 1.5 MW and 575v. The wind turbines are divided into three SCIG fixed-speed wind turbines and three DFIG variable speed wind turbines. Fig. 11 shows the block diagram of the studied system. A three phase fault is applied at 25 s and removes [e1] the fault after time equal 25.15 s.

VII. SIMULATION RESULTS

The simulation studied the performance of CWF with ANN-SSSC and CWF with ordinary SSSC (PI-SSSC) during three-phase fault. The voltage, reactive power and active power are measured at the point connection between the interconnected grid and wind farms.

The value of the control parameters of ordinary SSSC, MOGA SSSC and the proposed ANN SSSC are shown in Table II.

TABLE II. THE VALUE OF GAINS OF AC VOLTAGE, DC VOLTAGE REGULATORS OF ORDINARY SSSC, MOGA SSSC AND ANN SSSC

| Type of SSSC | Regulator | Gain value |
|-------------|-----------|------------|
| ordinary SSSC | AC voltage | Kp_Vac, 3.75e-3 |
|              | Ki_Vac, 0.1875 |
|              | DC voltage | Kp_Vdc, 0.1e-3 |
|              | Ki_Vdc, 20e-3 |
| MOGA SSSC | AC voltage | Kp_Vac, 0.24742 |
|            | Ki_Vac, 0.98783 |
|            | Kp_Vdc, 0.06939 |
|            | Ki_Vdc, 0.95957 |
| proposed ANN SSSC | AC voltage | Kp_Vac, 0.1107 |
|                  | Ki_Vac, 0.8665 |
|                  | Kp_Vdc, 0.0753 |
|                  | Ki_Vdc, 0.8686 |

A. Impact of Three Fault

As illustrated in Fig. 12 the voltage with ANN-SSSC is 0.81 pu while the voltage with ordinary SSSC is 0.73 pu and the voltage with MOGA-SSSC is 0.75 pu. This means that the voltage of CWF has been improved with ANN-SSSC more than with the ordinary SSSC.

As illustrated in Fig. 14, the injected voltage of SSSC has been increased when it is controlled by ANN specially at the begging of fault period. This will decrease the reactive power absorbed by the CWF with ANN SSSC during fault.

As illustrated in Fig. 14, the injected voltage of SSSC has been increased when it is controlled by ANN specially at the begging of fault period. This will decrease the reactive power absorbed by the CWF with ANN SSSC during fault.

As illustrated in Fig. 14, the injected voltage of SSSC has been increased when it is controlled by ANN specially at the begging of fault period. This will decrease the reactive power absorbed by the CWF with ANN SSSC during fault.

As illustrated in Fig. 14, the injected voltage of SSSC has been increased when it is controlled by ANN specially at the begging of fault period. This will decrease the reactive power absorbed by the CWF with ANN SSSC during fault.
As illustrated in Fig. 15 the active power of CWF with ANN-SSSC has the highest value of output power especially at the beginning of fault period.

In order to justify the good performance of the proposed method, root mean square Error (RMSE) is used to measure the impact of ordinary SSSC, MOGA SSSC, and ANN SSSC on the performance of CWF during the fault. RMSE is used to measure the error between the reference voltage (Vref = 1 pu) and the actual voltage at the point of common connection during the fault condition. Table III shows the RMSE of the three cases during fault period and after fault clearance.

| Period                      | Ordinary SSSC | MOGA SSSC | ANN SSSC |
|-----------------------------|--------------|-----------|----------|
| RMSE during fault period    | 0.2063       | 0.1959    | 0.1805   |
| RMSE after fault clearance  | 0.1918       | 0.1721    | 0.1405   |

From Table III, it can be observed that the CWF with ANN SSSC has the lowest RMSE. This means that the ANN managed to tune SSSC and gives the best result.

VIII. CONCLUSIONS

This paper has presented the design of a CWF which consists of two types of induction generator, the first one is SCIG fixed speed wind turbines and the second one is DFIG variable speed wind turbines. ANN has been used in order to adjust SSSC’s parameters to enhance the performance of combined wind farm (CWF). In addition, this paper includes a comparison among the performances of combined wind farm (CWF) with ANN-SSSC, with performances of CWF with ordinary SSSC and performances of CWF with SSSC tune by Multi-objective genetic algorithm (MOGA SSSC). The performances of CWF with ANN-SSSC, ordinary and SSSC MOGA SSSC have been studied during the three-phase fault. The obtained results showed that the adjusted SSSC using ANN has enhanced the active power, the voltage and the reactive power of CWF, particularly during the three-phase fault.

IX. FUTURE WORK

This paper opens the door for many future works, for example:
1. Using ANN hybrid with different methods of optimization to determine optimal values for different types of FACTS to improve the performance of wind stations.
2. Use different types of ANN like ANFIS with different methods of optimization to determine optimal values for different types of FACTS to improve wind station performance.

ACKNOWLEDGMENT
