Malignant transformation of mature cystic teratoma is uncommon, and occurs in approximately 2%–4% of cases.1 The most common tumor is squamous cell carcinoma, followed by mucinous carcinoma, carcinoid tumor, thyroid carcinoma, etc.; however, any of the tissues in mature teratoma may undergo malignant transformation.1

Goblet cell carcinoid (mucinous carcinoid) is a distinctive neoplasm with features of both carcinoid tumor and adenocarcinoma. Most cases described in the literature have occurred in the appendix and rarely, in the ovary. Although mature cystic teratomas occur in many extragonadal areas including the mesentery2 and greater omentum, occurrence of goblet cell carcinoid arising in extragonadal teratoma has been rarely described, with only a single case in mediastinum being reported in the English literature.3 Moreover, a combination of mucinous adenocarcinoma, goblet cell carcinoid, carcinoid tumor, and mature teratoma in an extragenital organ has not been reported.

Herein, we present a rare case of combined mucinous adenocarcinoma and goblet cell and typical carcinoid tumor arising in mature cystic teratoma of the mesentery in a 48-year-old woman.

CASE REPORT

A 48-year-old woman presented with a palpable abdominal mass in the periumbilical area with a vague abdominal pain of one month duration. Past medical history was unremarkable. She had no symptoms of carcinoid syndrome. On physical examination, the abdomen was markedly distended due to a solid movable mass. Abdominal and pelvic computed tomography scans revealed a huge heterogeneously enhanced mass in the abdominal cavity, which was associated with multiple smaller nodules throughout the entire abdominal and pelvic cavities and the right lobe of the liver. Bilateral ovaries were diffusely enlarged to form a semisolid mass. Laboratory findings demonstrated increased serum levels of carcinoembryonic antigen (264 ng/mL; normal < 6 ng/mL) and carbohydrate antigen 125 (294 U/mL, normal < 35 U/ml). Alpha-fetoprotein, beta-subunit of human chorionic gonadotropin and carcinohydate antigen-19-9 were within normal range.

Exploratory laparotomy revealed a huge mass in the mesentery of the small intestine (Fig. 1A), measuring 20×18×11 cm, with coexisting multiple outbulging hepatic masses, bilateral ovarian masses, and diffusely seeding nodules on the peritoneal surface and omentum. On cut section, the mesenteric mass had solid and cystic portions. The cystic portion, occupying approximately 60% of the tumor, was filled with yellow-tan sebum-like materials, hair, mucoid and gelatinous substances, while the solid portion (40%) was composed of loose myxoid tissue (Fig. 1B). Bilateral ovaries were enlarged, measuring 12.5×8×6 cm in the right ovary and 10×6×3 cm in the left ovary, and multiple gelatious tumor nodules were observed on both ovarian surfaces and parenchyma (Fig. 1C). The cut surface of the ovarian masses was greyish white and gelatious. The seeding nodules of the peritoneal surface and omentum had myxoid and gelatinous appearances. Excision of the mesenteric mass, bilateral salpingo-oophorectomy, total omentectomy and appendectomy were undertaken. Intraoperative frozen sections were per-
formed for the ovarian mass, and the diagnosis was mucinous adenocarcinoma.

On microscopic examinations, the mesenteric tumor was encapsulated by thick fibrous tissue. The cystic portion of the mesenteric mass showed characteristic histologic features of mature teratoma containing various mature tissues derived from all three germ layers, including skin and its appendages, salivary glands, cartilage, adipose tissue, and smooth muscle bundles (Fig. 2A). The adjacent solid portion showed various histologic features of carcinoïd tumors; a 1.5-cm sized well-circumscribed nodule showing insular, small glandular, rosetted, and solid tubular patterns similar to those of midgut (insular) carcinoïd tumors, thin cord-like or anastomosing trabecular patterns resembling hindgut (trabecular) carcinoïd tumors, and dissecting mucin pools containing floating tumor cells (Fig. 2A, B), suggesting goblet cell carcinoïd tumor. The insular and trabecular carcinoïd tumor cells were composed of uniformly small and round nuclei with finely stippled chromatin, and abundant cytoplasm with eosinophilic granules. Mitotic figures were rare in insular and trabecular carcinoïd areas (Ki-67 labeling index was less than 2%). The tumor cells within mucin pools were individually scattered or formed small nests having signet ring cell-like or goblet cell appearances, abundant foamy cytoplasm, low nuclear cytoplasmic ratio, and flattened nuclei pushed to the periphery (Fig. 2B). There was mild variation in nuclear sizes, mitotic figures were rarely identified, and Ki-67 labeling index was low (less than 2%) (Fig. 2B). On immunohistochemical stains, the trabecular and insular carcinoïd tumor components showed strong and diffuse immunoreactivity for synaptophysin (Fig. 2C) and focal immunoreactivity for chromogranin. The tumor cells within mucin pools showed multifocal immunoreactivity for synaptophysin (Fig. 2B inset).

In the vicinity of the carcinoïd tumors, there were mucin pools containing signet ring cell-like or goblet cells showing significantly enlarged nuclei with high nuclear cytoplasmic ratio, marked nuclear pleomorphism, prominent nucleoli, and frequent mitotic figures (Fig. 2D). Immunohistochemical stain for synaptophysin was completely lost in the malignant signet ring cell-like tumor cells, and proliferating cells defined by Ki-67 immunohistochemical stains were significantly increased, up to 20%,
in those malignant cells. The two areas containing the signet ring cell-like appearance with and without nuclear pleomorphism were intermingled with each other and the border could not be clearly delineated.

Both ovaries were mostly replaced by tumor tissue with a multinodular appearance. Each nodule was well-circumscribed and was composed of a mucin pool containing signet ring cells identical to those in the mesenteric mass (Fig. 3A). Extraovarian mucin pools were also noted in the omentum and serosal surfaces of the pelvic organs, forming pseudomyxoma peritonei (Fig. 3B). There were no insular or trabecular carcinoid areas in either ovarian tumor.

The patient received five cycles of adjuvant chemotherapy with paclitaxel and cisplatin, but she died of multiorgan metastasis eight months postoperatively.

**DISCUSSION**

Historically, a tumor describing mixed glandular and neuroendocrine neoplasm has had many synonyms, including goblet cell carcinoid, mucinous carcinoid, adenocarcinoid, microglandular carcinoma, intermediate cell carcinoid, amphicrine neoplasia, and composite tumor. There remains confusion and debate regarding the terminologies amongst pathologists and clinicians. In the appendix and ovaries, intimately admixed glandular and neuroendocrine neoplasm composed of goblet cells, neuroendocrine cells, or hybrid cells containing both mucin and neuroendocrine granules floating in pools of mucin are designated as goblet cell carcinoid. Goblet cell carcinoid tumors in the appendix present in four types: 1) pure and uniform tubules composed entirely of goblet cells; 2) goblet cell carcinoid with...
adenocarcinomatous area (adenocarcinoma ex goblet cell carcinoid); 3) goblet cell carcinoid with mucinous cystadenoma; and 4) the combined classical carcinoid with goblet cell carcinoid tumor. In our case, goblet cell carcinoid was combined with mucinous adenocarcinoma and additional typical insular and trabecular carcinoid tumor. Histologically, it is not easy to distinguish the pure goblet cell carcinoid from mucinous adenocarcinoma arising in goblet cell carcinoid tumors because of the same goblet cell morphology in mucin pools in both tumors and intimately admixed tumor components in most cases. Goblet cell carcinoid tumors have more aggressive clinical behaviors, showing metastasis in 20% of cases, compared to the classic type of carcinoid tumor, but the tumors have relatively favorable prognosis compared to the mucinous adenocarcinoma ex goblet cell carcinoid. Pools of mucin are usually small in goblet cell carcinoid and they usually lie within the glands or in the periglandular stroma. The nuclear atypia is not significant in goblet cell carcinoid; however, mucinous adenocarcinoma ex goblet cell carcinoid has greater nuclear pleomorphism, higher mitotic rate, and Ki-67 proliferating activity, which can lead to a diagnosis of mucinous adenocarcinoma ex goblet cell carcinoid.

Histogenetically, two neoplasms in adjacent but separate areas are designated as a collision tumor of a biclonal derivation, while composite tumors having intimate admixture of the two components are believed to result from bidirectional differentiation of a single neoplasm. A molecular study suggested that goblet cell carcinoid has similar expression patterns of genes for secretory and Paneth cell differentiation to those of mucinous cystadenomas and colonic adenocarcinomas; thus, goblet cell carcinoids are closer to colonic adenocarcinomas than to classical carcinoids, implicating that the goblet cell carcinoid probably arises in progenitor cells of the epithelial crypt.

Rarely, mature cystic teratomas have been described in the mesentery and greater omentum. The pathogenetic origin is explained as primitive germ cells entrapped during embryonic development, a supernumerary (ectopic) ovary located in the omentum, or secondary implantation of a teratomatous component to the omentum following the torsion and rupture of ovarian teratoma.

The diagnosis of extra-appendiceal and extraovarian goblet cell carcinoid should be determined after thorough examination of the two organs and exclusion of appendiceal or ovarian origins. The patient in our case received an appendectomy at the same time, which was thoroughly examined, but only serosal tumor implants were identified. Mucinous adenocarcinoma involved bilateral ovaries in our case; however, the ovaries were thought to be metastatic sites because of their bilateral multinodular appearance, and involvement of the ovarian surface and superficial cortex of the ovary only. A significant amount of mucin pools dissecting the ovarian stroma and signet ring cell-like morphology are extremely rare in primary mucinous adenocarcinoma of the ovary. Moreover, the existence of mesenteric mature teratoma and significantly larger extraovarian mucin pools forming pseudomyxoma peritonei are supporting features of extraovarian origin.

This case had combined features of several rare findings: primary mesenteric mature teratoma associated with carcinoid tu-
mor, coexistence of all three types of carcinoid tumors including insular, trabecular and goblet cell carcinoid, overgrown mucinous adenocarcinoma of goblet cell morphology in the background of goblet cell carcinoid, metastasis of extragonadal goblet cell carcinoid to the ovaries, and formation of pseudomyxoma peritonei from extra-appendiceal neoplasm, but the clinical course followed those of mucinous adenocarcinoma and high grade pseudomyxoma peritonei. Recognition of mucinous adenocarcinoma components seems to be closely correlated with the patient’s prognosis. Thus, careful histological observation is required to make a clinically relevant diagnosis.
