Abstract
We study the condition that the theory is unitary and stable in three-dimensional gravity with the most general quadratic curvature, Lorentz–Chern–Simons and cosmological terms. We provide the complete classification of the unitary theories around flat Minkowski and (anti-)de Sitter spacetimes. The analysis is performed by examining the quadratic fluctuations around these classical vacua. We also discuss how to understand the critical condition for four-dimensional theories at the Lagrangian level.

1. Introduction

The quest for a quantum theory of gravity is one of the long-standing problems in theoretical physics. The usual Einstein gravity suffers from the problem that the theory is non-renormalizable in four and higher dimensions. The addition of higher derivative terms such as Ricci and scalar curvature-squared terms makes the theory renormalizable at the cost of the loss of unitarity [1]. Of course, unitarity is quite important in any physical theory. Otherwise, the theory does not make sense.

Recently, a very interesting proposal has been made that the addition of such higher order terms to three-dimensional gravity makes the theory unitary and possibly renormalizable if the coefficients are chosen appropriately [2]. The usual Einstein gravity does not have any propagating mode, but the addition of these terms introduces propagating massive graviton around flat Minkowski and curved maximally symmetric spacetimes (anti de Sitter (AdS) and de Sitter (dS) spacetimes). The theory of massive graviton with the Lorentz–Chern–Simons (LCS) term has long been known as topologically massive theory [3], but the theory violates parity. In contrast, the new theory is a parity-preserving theory and called new massive gravity. This is very interesting in that we have really dynamical theory of gravity that is unitary even though higher derivative terms are included. Since then, various aspects of the theory have been investigated. Linearized excitations in the field equations were studied in [4]. Unitarity...
In 

and renormalizability are studied in [5], though the issue of renormalizability is not on a firm foundation [6, 7]. Unitarity is proven for Minkowski spacetime in [6, 8], whereas it is discussed in [9] for maximally symmetric spacetimes. Supergravity extension is discussed in [10, 11]. The critical case is studied in [12]. The partial result of a unitarity condition on flat Minkowski spacetime was known for the usual sign of the Einstein theory [13]. A related discussion based on the AdS/CFT correspondence is given in [14].

Although this kind of theories have their own significance, it is also known that such higher order terms are present in the low-energy effective theories of superstrings. There is some ambiguity in such theories due to the field redefinition. If the above approach of requiring unitarity determines the coefficients to a certain extent, it may cast some light on the superstrings themselves.

The theory in question contains Einstein, Ricci tensor-squared, scalar curvature-squared terms as well as the LCS term. The analysis is made that for what range of these parameters, the theory is unitary on flat Minkowski spacetime in [10, 6, 8], and on maximally symmetric spacetimes in [9]. (For the dS case, see also [8].) To understand the problem of unitarity, the analysis of field equations is not enough. We should look at the quadratic fluctuations of the theory around possible vacua in the Lagrangian and check if the physical particles have correct sign for kinetic terms. This off-shell analysis has been made in [6] for the theory around Minkowski vacuum, in [8, 10] for that with the LCS term around Minkowski, and in [9] for that around maximally symmetric spacetimes but without the LCS term and with a particular relation between some coefficients obtained for Minkowski spacetime from the outset. However, whether the theory makes sense or not should be studied for each vacuum; if it is unitary around a vacuum but not on the other, we should simply consider the theory near the sensible vacuum. Thus, the complete classification of the unitary and stable theory (for which range of parameters the theory is unitary and stable) including the LCS term with arbitrary coefficients for the theory on the maximally symmetric spacetimes is lacking. One of the purposes of this paper is to fill this gap and provide a complete classification of possible unitary and stable theory for three-dimensional gravity, with all terms and arbitrary coefficients, by looking at the quadratic fluctuation of the theory around these vacua in the Lagrangian. In this way, we also resolve a problem left unresolved in [12] if the unitarity of the AdS irreps is enough to ensure the unitarity of the field theory; the answer is negative, and we are able to identify which range of the parameters allows unitary and stable theory. This can be done only in the off-shell analysis. We also find that there is a certain parameter region that has not been explored before.

When the theory is considered around maximally symmetric spacetimes (including Minkowski spacetime), it turns out that the theory is unitary and stable for the ‘wrong’ sign of the Einstein term if the Ricci tensor squared is present. This means that the Einstein gravity may not be obtained in the low-energy approximation to the theory in that case. The question then arises if this could be remedied, and also what happens in the four-dimensional case. In this connection, the three-dimensional critical theory was proposed with the usual sign for the Einstein term, LCS and cosmological constant terms [15], and it was argued that the unitarity might be recovered in the critical case with a particular relation between the cosmological constant and the mass term. Motivated by this, an interesting proposal of critical gravity in four and higher dimensions has been made [17, 18]. It has been suggested that in this critical theory, the theory may be unitary by imposing suitable boundary conditions to eliminate some modes. However, there arise additional logarithmic modes [19, 20] and it has been pointed out that there may be a trouble with the unitarity [21]. Also, even if ghost modes can be eliminated by boundary conditions, the question still remains whether the theory makes sense or not at the quantum level. This issue has to be examined further. Much of the study so
far is based on the field equations, but once again we emphasize that the off-shell approach is the most suitable way to study this problem. In view of this situation, we attempt to understand this problem by extending our analysis from three to four dimensions. A related discussion is given in the appendix of [22].

We should mention that some extensions of critical gravity to include further higher order terms [23] and supergravity [24] have been considered. See also [25].

This paper is organized as follows. In section 2, we present the general theory that we study in this paper with Einstein, scalar curvature-squared, Ricci squared, cosmological and topological mass terms with arbitrary coefficients. We then proceed to the study of the condition for the unitarity and stability around flat Minkowski spacetime in section 3 and that around maximally symmetric spacetimes in section 4 by examining the quadratic fluctuations in the Lagrangian. We find the complete conditions for each case and also examine the critical conditions. In section 4, we present some formulae for studying the quadratic fluctuations in general dimensions and use them to discuss the critical conditions in four dimensions. In this way, we get some new view on the criticality in gravitational theory. Section 5 is devoted to our conclusions and discussions. The appendix collects some useful formulae necessary in the text.

2. The most general theory

We consider the action

\[ S = \frac{1}{\kappa^2} \int d^3x \sqrt{-g} \left\{ \sigma R - 2\Lambda_0 + \alpha R^2 + \beta R_{\mu\nu}^2 \right\} + L_{\text{LCS}}, \]

(2.1)

where \( \kappa^2 \) is the three-dimensional gravitational constant, \( \alpha, \beta, \mu, \sigma(= 0, \pm 1) \) are constants, \( \Lambda_0 \) is a cosmological constant and the last term is the LCS term:

\[ L_{\text{LCS}} = \frac{1}{2\mu} \epsilon^{\mu\nu\rho} \left( \Gamma^\alpha_{\mu\beta} \partial_\nu \Gamma^\beta_{\rho\alpha} + \frac{2}{3} \Gamma^\alpha_{\mu\gamma} \Gamma^\gamma_{\nu\beta} \Gamma^\beta_{\rho\alpha} \right). \]

(2.2)

Here, \( \Gamma \) is the usual Levi-Civita connection for the spacetime metric \( g \). Our conventions are summarized in the appendix.

The variation of each term gives the field equations:

\[ \sigma G_{\mu\nu} + \Lambda_0 g_{\mu\nu} + \alpha E^{(1)}_{\mu\nu} + \beta E^{(2)}_{\mu\nu} + \frac{1}{\mu} C_{\mu\nu} = 0, \]

(2.3)

where

\[ G_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu}, \]
\[ E^{(1)}_{\mu\nu} = 2R g_{\mu\nu} - 2 \nabla_\mu \nabla_\nu R + g_{\mu\nu} \left( 2 \Box R - \frac{1}{2} R^2 \right), \]
\[ E^{(2)}_{\mu\nu} = 2R_{\mu\lambda} R^{\lambda}_{\nu} - 2 \nabla_\mu \nabla_\nu R + 2 \nabla_\mu (\Box R) g_{\nu\lambda} + \frac{1}{2} (\Box R - R^2) \Box g_{\mu\nu}, \]
\[ C_{\mu\nu} = \epsilon^{\alpha\beta\gamma} \nabla_\alpha (R_{\beta\gamma} - \frac{1}{4} g_{\beta\gamma} R). \]

(2.4)

Here, \( G_{\mu\nu} \) and \( C_{\mu\nu} \) are known as Einstein and Cotton tensors, respectively.

There are two possible vacua in the theory: Minkowski and maximally symmetric spacetimes of (A)dS. Here, we wish to study the range of the coefficients for which the theory is unitary (no ghost) and stable. There have been several studies, but as far as we are aware, there is no study of the system with the most general parameters.

We consider the action up to second order around the background spacetime

\[ g_{\mu\nu} = \bar{g}_{\mu\nu} + \kappa h_{\mu\nu}, \]

(2.5)
where the background $\bar{g}_{\mu\nu}$ is chosen to be a maximally symmetric spacetime with the Riemann curvature
\[
\bar{R}^\alpha_{\beta\mu\nu} = \Lambda \left( \bar{g}^\alpha_{\mu\nu} \bar{g}_{\rho\sigma} - \bar{g}^\mu_{\rho} \bar{g}^\nu_{\sigma} \right),
\] (2.6)
with the Minkowski spacetime corresponding to $\Lambda = 0$. We define
\[
h \equiv \bar{g}^{\mu\nu} h_{\mu\nu}, \quad h_{\mu} \equiv \nabla^{\mu} h_{\mu\nu}.
\] (2.7)
Here, and in what follows, bar indicates that the quantity stands for the background, the indices are raised and lowered by the background metric $\bar{g}$, the covariant derivative $\nabla$ is constructed with the background metric, and the contraction is also understood by that. This is a solution of the system (2.1) provided that
\[
\Lambda_0 = \sigma \Lambda - 2(3\alpha + \beta) \Lambda^2.
\] (2.8)
We see that the cosmological constant $\Lambda_0$ should be zero in order to have a Minkowski spacetime.

3. Theory around Minkowski spacetime

In this section, we consider the theory in flat Minkowski spacetime which is realized for $\Lambda_0 = 0$. We study that in what ranges of the parameters, the theory (2.1) becomes unitary and stable setting $\bar{g}_{\mu\nu} = \eta_{\mu\nu}$.

For this purpose, we decompose $h_{\mu\nu}$ into their orthogonal parts [6]:
\[
h_{ij} = 2\partial_i h_j + \epsilon_i^j \phi_{kl}, \quad h_{0i} = \eta_i + \epsilon_i^j \psi_j, \quad h_{00} = n.
\] (3.1)
Subscripts on the indexless variables $(\phi, \eta, \psi)$ denote normalized spatial derivatives $\partial_i/\sqrt{-\bar{g}}$, where $\partial_i^2 = \partial_i^2 + \partial_j^2$ is the two-dimensional Laplacian. Gauge invariance of the action (2.1) allows us to set the three gauge parts $h_i$ and $\eta$ of the metric to zero by imposing the usual gauge choice $h_{ij,j} = h_{0i,j} = 0$. There remain only the three gauge-invariant components $(\phi, \psi$ and $n)$ in (3.1).

The Einstein tensor has the components
\[
G_{00} = \frac{1}{4} \partial^2_\phi \phi, \quad G_{0i} = \frac{1}{4} \left( \partial_i \phi - \epsilon_i^j \partial^2 \psi_j \right),
\]
\[G_{ij} = -\frac{1}{4} \left[ \phi_{ij} - \epsilon_i^k \epsilon_j^l \partial^2 n_{kl} + \epsilon_i^k \sqrt{-\bar{g}} \partial_k \psi_{kl} + \epsilon_j^k \sqrt{-\bar{g}} \partial_k \psi_{kl} \right],
\] (3.2)
where subscripts on $n$ also represent normalized spatial derivatives. Substituting these into the action (2.1) and keeping terms up to second order, we find
\[
S = \int d^4x \left[ \frac{\beta}{2} \bar{\psi} \bar{\psi} + \frac{\sigma}{2} \bar{\psi}^2 + \left( \alpha + \frac{\beta}{2} \right) \left( \bar{\partial}_i^2 n + \left( \Box \phi \right)^2 \right) + \frac{\alpha + \beta}{4} \left( \bar{\partial}_i^2 n \right) \right],
\]
\[\frac{\sigma}{2} \bar{\psi} \bar{\partial}^2 n + \left. \left. \left. \frac{1}{2} \bar{\psi} \left( \bar{\partial}_i^2 n - \Box \phi \right) \right] \right],
\] (3.3)
where we have defined $\bar{\psi} \equiv \partial_i \psi_i = -\sqrt{-\bar{g}} \bar{\psi}$ and $\Box \equiv \nabla^2$. Because $-\bar{\partial}_i^2$ is a positive operator, this causes no problem. There are intrinsically two distinct cases to be discussed separately, depending on whether $\alpha + \frac{\beta}{2}$ is zero or not.

3.1. $\alpha + \frac{\beta}{2} \neq 0$ case

If $\alpha + \frac{\beta}{2}$ is not zero, the Lagrangian from the second-order action (3.3) can be transformed into
\[
\mathcal{L}_2 = \left( \alpha + \frac{\beta}{2} \right) \left( \bar{\partial}_i^2 n + \left( \alpha + \frac{\beta}{2} \right) \frac{\phi - \frac{\sigma}{2} \frac{1}{2} \bar{\psi}}{\alpha + \frac{\beta}{2}} \right)^2 - \frac{(\alpha + \frac{3}{2} \beta) \beta}{\alpha + \frac{\beta}{2}} \left( \Box \phi \right)^2 + \cdots.
\] (3.4)
The first term simply indicates that the non-dynamical field \( n \) is determined in terms of other fields. The second term denotes that the theory has a dipole ghost unless \((\alpha + \frac{3}{8} \beta) \beta = 0\), which gives the first constraint. So, we have to further divide the cases.

3.1.1. Subcase \( \alpha + \frac{3}{8} \beta = 0 \). In this case, we have \( \beta \neq 0 \) from \( \alpha + \frac{\beta}{2} \neq 0 \). Dropping the first term in (3.4), our action (3.3) then gives

\[
\mathcal{L}_2 = \frac{1}{2} \beta \Box + \sigma + \frac{1}{2} \beta \mu \right) \frac{1}{2} \psi \right) + \frac{\sigma}{\beta} \phi - \phi \left( \frac{\sigma}{2} \right) \phi. \tag{3.5}
\]

Here, we see that the inclusion of the LCS term only modifies the mass spectrum, but does not affect whether the theory contains ghost or not. In order for the \( \psi \) and \( \phi \) fields not to be ghost, we have to have

\[
\beta > 0, \quad \sigma \leq 0. \tag{3.6}
\]

The case \( \sigma = 0 \) is found by Deser [6], but the LCS term was not considered there. In this case, we have only one dynamical mode with mass squared:

\[
m^2 = \frac{1}{\beta \mu}, \tag{3.7}
\]

For \( \sigma = -1 \), we have two modes with the spectrum:

\[
m^2 = - \sigma + \frac{1}{2(\beta \mu)^2} \left[ 1 + \sqrt{1 - 4 \sigma \beta \mu} \right], \tag{3.8}
\]

which are always positive for (3.6). So, the theory is also free from tachyons. The action becomes

\[
S = \frac{1}{2 \kappa^2} \int d^3x \sqrt{-\gamma} \left[ \sigma R + \beta \left( R_{\mu \nu}^2 - \frac{3}{8} R^2 \right) \right] + \mathcal{L}_{\text{LCS}} \right) \tag{3.9}
\]

with condition (3.6). This is the new massive gravity [2] with the LCS term. In the limit \( \beta \rightarrow 0 \), one of the spectra diverges and decouples and we are left with a single mode with the mass

\[
m^2 = \mu^2. \tag{3.10}
\]

This is the well-known topological gravity [3].

3.1.2. Subcase \( \beta = 0 \). Together with \( \alpha + \frac{\beta}{2} \neq 0 \), we have \( \alpha \neq 0 \). Dropping the non-dynamical first term in (3.4), our action (3.3) then gives

\[
\mathcal{L}_2 = \left( \frac{\sigma}{2} - \frac{1}{16 \alpha \mu \xi^2} \right) \psi^2 + \left( \sigma \frac{\phi}{8 \alpha \mu} - \frac{1}{\mu} \Box \right) \psi + \phi \left( \frac{\sigma}{2} - \frac{\sigma^2}{16 \alpha} \right) \phi
\]

Diagonalizing this kinetic term, we see that the system always has modes of opposite norm unless we send \( \mu \) to infinity. This can be most easily checked by taking the determinant of the kinetic term matrix. In the limit \( \mu \rightarrow \infty \), however, the mixing of \( \psi \) and \( \phi \) is turned off, and we are left with

\[
\mathcal{L}_2 = \frac{1}{2} \psi^2 + \phi \left( \frac{\sigma}{2} - \frac{\sigma^2}{16 \alpha} \right) \phi \tag{3.11}
\]

Thus, we must have

\[
\sigma = +1. \tag{3.12}
\]
in order to be free from ghost (σ = 0 gives trivial theory), and
\[ \alpha > 0, \]
(3.14)
in order to be free from tachyons. This is a special case of \( f(R) \) gravity known to be free from ghosts. Since higher order terms in \( R \) do not affect the quadratic fluctuation in flat Minkowski spacetime, this conclusion is valid if we include higher orders in \( R \). However, the result may change if we consider the theory in non-trivial backgrounds.

3.2. \( \alpha + \frac{\beta}{2} = 0 \) case

Our action (3.4) reduces to
\[
\mathcal{L}_2 = \left( \tilde{\psi}, \tilde{\sigma}, h, \phi \right) \begin{pmatrix}
\frac{3}{4} \Box + \frac{3}{8} & \frac{1}{4} & -\frac{1}{4} \Box \\
\frac{1}{4} & 0 & -\frac{1}{4} (\Box + \sigma) \\
-\frac{1}{4} \Box & -\frac{1}{4} (\Box + \sigma) & 0
\end{pmatrix} \begin{pmatrix}
\tilde{\psi} \\
\tilde{\sigma} h \\
\phi
\end{pmatrix}.
\]
(3.15)
It is clear that in the limit \( \mu \to \infty \), we have one mode of norm determined by the sign of \( \beta \) and two modes of opposite norm from the two linear combinations of \( \tilde{\sigma} h \) and \( \phi \). Hence, the theory always has at least one ghost. When \( \mu \) term sets in, this conclusion does not change because these terms do not affect the sign of the highest power of \( \Box \). We thus conclude that there is no unitary theory in this case.

To summarize the result of this section, we have unitary theory around the Minkowski vacuum for the cases listed in table 1. This result agrees with those derived in [8, 10] in a slightly different gauge.

4. Theory around maximally symmetric spacetimes

We now turn to the study of the general theory around maximally symmetric spacetimes.

Expanding the action (2.1) around the maximally symmetric spacetimes and eliminating \( \Lambda_0 \) in terms of \( \Lambda \) via (2.8), we find that the linear term vanishes due to (2.8), and the second-order terms give
\[
\mathcal{L}_2 = \sigma \left[ R^{(2)} + R^{(1)} h + \frac{1}{2} \Lambda (h^2 - 2h^2_{\mu\nu}) \right] \\
+ \alpha \left[ R^{(1)^2} + 12 \Lambda R^{(2)} + 6 \Lambda R^{(1)} h + 6 \Lambda^2 (h^2 - 2h^2_{\mu\nu}) \right] \\
+ \beta \left[ R^{(1)^2} + 4 \Lambda g^{\mu\nu} R^{(2)} - 8 \Lambda h^{\mu\nu} R^{(1)} \right] + 2 \Lambda g^{\mu\nu} R^{(1)^2} + 2 \Lambda^2 h^2_{\mu\nu} - 2 \Lambda^2 h^2 \\
+ \mathcal{L}_{\text{LCS,2}},
\]
(4.1)
where \( R^{(1,2)} \) and \( R^{(1,2)^{\mu\nu}} \) are defined in the appendix and \( \mathcal{L}_{\text{LCS}} \) is the contribution from the LCS term (2.2). These can be expressed in terms of
\[
\mathcal{G}_{\mu\nu}(h) \equiv R^{(1)}_{\mu\nu} - \frac{1}{2} R^{(1)^2} g_{\mu\nu} - 2 \Lambda h_{\mu\nu},
\]
\[
= - \frac{1}{2} \left[ \nabla_{\mu} \nabla_{\nu} h - \nabla_{\mu} h_{\nu} - \nabla_{\nu} h_{\mu} + \Box h_{\mu\nu} + (\nabla_{\mu} h^{k} - \Box h^{\mu}) g_{\mu\nu} \right] + \Lambda h_{\mu\nu}.
\]
(4.2)
Summing up all terms, the final result is
\[ \mathcal{L}_2 = \left[ 2 \Lambda (3 \alpha + \beta) + \frac{\sigma}{2} \right] h^{\mu\nu} \mathcal{G}_{\mu\nu}(h) + \beta [\mathcal{G}_{\mu\nu}(h)]^2 + (4 \alpha + \beta) [\mathcal{G}_{\mu}(h)]^2 + \mathcal{L}_{\text{LCS,2}}, \] (4.4)
where
\[ \mathcal{L}_{\text{LCS,2}} = \frac{1}{4 \mu^2} \epsilon^{\mu\nu\rho\sigma} \mathcal{H}_{\mu\nu} \nabla_\rho \left[ \left( \Box h^\lambda_\rho - 2 \Lambda h^\lambda_\rho \right) - \nabla^\lambda h_\rho \right]. \] (4.5)

Indeed, eliminating \( k_{\mu\nu} \) by its field equation, we recover result (4.4). For \( \alpha = \frac{1}{3\pi^2}, \beta = \frac{1}{\pi^2}, \) and \( \mu = \infty, \) this agrees with the result in [9] without the LCS term.

We take the parametrization [16]
\[ h_{\mu\nu} = h^T_{\mu\nu} + \nabla_\mu \xi_\nu + \nabla_\nu \xi_\mu + \nabla_\mu \nabla_\nu \eta - \frac{1}{2} \bar{g}_{\mu\nu} \Box \eta + \frac{1}{3} \bar{g}_{\mu\nu} h, \] (4.9)
with
\[ \nabla^\lambda h^T_{\mu\nu} = 0, \quad \bar{g}^{\mu\nu} h^T_{\mu\nu} = 0, \quad \nabla^\lambda \xi_\lambda = 0. \] (4.10)

First, substituting (4.9) into (4.2), we obtain
\[ \mathcal{G}_{\mu\nu} = -\frac{1}{2} \left[ \left( \Box - 2 \Lambda \right) h^T_{\mu\nu} - \frac{1}{3} \nabla_\mu \nabla_\nu \Box \eta + \frac{1}{3} \Box (\Box + 2 \Lambda) h \bar{g}_{\mu\nu} + \frac{1}{3} \nabla_\mu \nabla_\nu h - \frac{1}{3} (\Box + 2 \Lambda) h \bar{g}_{\mu\nu} \right]. \] (4.11)

We then find that (4.4) gives
\[ \mathcal{L}_2 = \frac{1}{4} h^T_{\mu\nu} (\Box - 2 \Lambda) \left[ \left( \beta (\Box - 2 \Lambda) + 4 (3 \alpha + \beta) \Lambda + \sigma \right) \bar{g}^{\mu\rho} \bar{g}^{\nu\sigma} + \frac{1}{\mu} \epsilon^{\mu\lambda\rho} \bar{g}^{\nu\sigma} \nabla_\lambda \right] h^T_{\mu\nu} \]
\[ + \frac{1}{18} \hat{\eta} \left[ (8 \alpha + 3 \beta) \Box + 4 (3 \alpha + \beta) \Lambda - \sigma \right] \Box \hat{\eta} \]
\[ - \frac{1}{9} h [(8 \alpha + 3 \beta) \Box + 4 (3 \alpha + \beta) \Lambda - \sigma] \sqrt{\Box} (\Box + 3 \Lambda) \hat{\eta} \]
\[ + \frac{1}{18} h [(8 \alpha + 3 \beta) \Box + 4 (3 \alpha + \beta) - \sigma] (\Box + 3 \Lambda) h, \] (4.12)
where the field redefinition
\[ \hat{\eta} \equiv \sqrt{\Box} (\Box + 3 \Lambda) \sigma, \quad \hat{\xi}_\mu \equiv \sqrt{\Box + 2 \Lambda} \xi_\mu \] (4.13)
has been made in order to compensate the Jacobian introduced in changing field variables from \( h_{\mu \nu} \) to (4.9) [16]. (\( \xi_{\mu} \) drops out from the gauge-invariant action here, but we shall have this in the following discussions of gauge-fixed theory.)

To this action, we add the gauge fixing and the corresponding Faddeev–Popov (FP) ghost terms:

\[
S_{gf} = \int d^3x \sqrt{-\hat{g}} \left[ -\frac{1}{2a} \hat{\chi}_{\mu} \hat{g}^{\mu \nu} \hat{\chi}_{\nu} + \frac{1}{\mu} \epsilon^{\mu \lambda \rho} \hat{g}_{\sigma} \nabla_{\lambda} \right],
\]

\[
S_{gh} = -\int d^3x \sqrt{-\hat{g}} C^\mu \left( \delta^\nu_\mu \hat{\square} + \frac{1 - b}{2} \nabla_\mu \nabla_\nu + R_\mu \right) C_\nu,
\]

where \( a \) and \( b \) are the constants and

\[
\chi_\nu = \nabla_\mu h^\mu_\nu - \frac{h + 1}{4} \nabla_\nu h.
\]

We find

\[
L_{gf} = -\frac{1}{2a} \left[ \hat{\chi}^\mu (\hat{\square} + 2\Lambda) \hat{\chi}_\mu - \frac{4}{9} \hat{\chi} (\hat{\square} + 3\Lambda) \hat{\eta} + \frac{3b - 1}{9} \hat{h} \sqrt{\hat{\square} (\hat{\square} + 3\Lambda) \hat{\eta}} - \frac{(3b - 1)^2}{144} \hat{h} \hat{\square} \hat{h} \right],
\]

\[
L_{gh} = -\hat{V}^\mu (\hat{\square} + 2\Lambda) \hat{V}_\mu + \hat{\xi} \left( \frac{3 - b}{2} \hat{\square} + 4\Lambda \right) \hat{\xi},
\]

where we have defined [16]

\[
C_\mu \equiv \hat{V}_\mu + \nabla_\mu S, \quad \hat{S} = \sqrt{\hat{\square}} S, \quad \nabla_\mu V^\mu = 0.
\]

\[
\hat{C}_\mu \equiv \hat{V}_\mu + \nabla_\mu \hat{S}, \quad \hat{\xi} = \sqrt{\hat{\square}} \hat{S}, \quad \nabla_\mu \hat{V}^\mu = 0.
\]

The total quadratic Lagrangian is

\[
L_2 = \frac{1}{4} \hat{h}^\mu_\nu (\hat{\square} + 2\Lambda) \left[ \beta (\hat{\square} - 2\Lambda) + 4(3\alpha + \beta) \Lambda + \sigma \hat{g}^{\mu \rho} \hat{g}^{\nu \sigma} + \frac{1}{\mu} \epsilon^{\mu \lambda \rho} \hat{g}_{\sigma} \nabla_\lambda \right] \hat{h}_\rho^{\nu} + \frac{1}{18} \hat{\eta} \left[ (8\alpha + 3\beta) \hat{\square}^2 + \left\{ 4(3\alpha + \beta) \Lambda - \sigma + \frac{4}{a} \hat{\square} + \frac{12}{a} \Lambda \right\} \hat{\eta} - \frac{1}{9} \hat{h} \left[ (8\alpha + 3\beta) \hat{\square} + 4(3\alpha + \beta) \Lambda - \sigma + \frac{3b - 1}{2a} \right] \sqrt{\hat{\square} (\hat{\square} + 3\Lambda) \hat{\eta}} + \frac{1}{18} \hat{h} \left[ (8\alpha + 3\beta) \hat{\square}^2 + \left\{ (36\alpha + 13\beta) \Lambda - \sigma + \frac{(3b - 1)^2}{16a} \right\} \hat{\eta} + 3(4(3\alpha + \beta) - \sigma) \Lambda \right] \hat{h} - 2a \hat{\xi} \left( \hat{\square} + 2\Lambda \right) \hat{\xi} - \hat{V}^\mu (\hat{\square} + 2\Lambda) \hat{V}_\mu \right.
\]

\[
+ \hat{\xi} \left( \frac{3 - b}{2} \hat{\square} + 4\Lambda \right) \hat{\xi}.
\]

Let us first consider the tensor part. Clearly, there are two kinds of modes in our Lagrangian (4.18): massless and massive. In order to study the no-ghost condition, we should look at the propagator and check if the residue at each pole is positive or not. To do this, let us consider the field equation

\[
\left[ \beta (\hat{\square} - 2\Lambda) + 4(3\alpha + \beta) \Lambda + \sigma \hat{g}^{\mu \rho} \hat{g}^{\nu \sigma} + \frac{1}{\mu} \epsilon^{\mu \lambda \rho} \hat{g}_{\sigma} \nabla_\lambda \right] \hat{h}_\rho^{\nu} = 0.
\]

Multiplying this with \( [\beta (\hat{\square} - 2\Lambda) + 4(3\alpha + \beta) \Lambda + \sigma] \hat{g}_{\alpha \mu} \hat{g}_{\beta \nu} - \frac{1}{\mu} \epsilon^{\alpha \lambda \rho} \hat{g}_{\sigma \nu} \nabla_\lambda \), we obtain

\[
\beta^2 (\hat{\square} - 2\Lambda - M^2_\beta) (\hat{\square} - 2\Lambda - M^2_\beta) h_\alpha^\rho = 0,
\]

(4.20)
where
\[
M^2_{\pm} = -\frac{4(3\alpha + \beta)\Lambda + \sigma}{\beta} + \frac{1}{2\beta^2\mu^2}[1 \pm \sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]}]. \tag{4.21}
\]
The operator \((\Box - 2\Lambda)\) corresponds to the Lichnerowicz operator for the second-rank tensors in curved spacetime and so its eigenvalues give the masses. The condition that the propagator has real massive poles in addition to the massless pole is that
\[
1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma] \geq 0, \tag{4.22}
\]
which we assume from now on. We shall see that the unitarity and stability of the theory require that \(\beta\{(12\alpha + 5\beta)\Lambda + \sigma\} < 0\), for which this is satisfied, and then, there is a smooth \(\mu \to \infty\) limit.

Thus, the propagator for \(h^{T}_{\mu\nu}\) which is given by the inverse of the quadratic term is found to be
\[
\frac{[\beta(\Box - 2\Lambda) + 4(3\alpha + \beta)\Lambda + \sigma]g^{\beta}_{\mu}(\mu\rho) - \frac{1}{\mu}e^{\alpha\lambda}(\mu\rho)\nabla_{\lambda}}{\beta^2(\Box - 2\Lambda)(\Box - 2\Lambda - M^2_+)(\Box - 2\Lambda - M^2_-)}, \tag{4.23}
\]
(suitable symmetrization in the indices is understood) which can be decomposed into three terms:
\[
\frac{A_{1\,\mu\nu}}{\beta^2(\Box - 2\Lambda)} + \frac{A_{-\,\mu\nu}}{\beta^2(\Box - 2\Lambda - M^2_+)} + \frac{A_{+\,\mu\nu}}{\beta^2(\Box - 2\Lambda - M^2_-)}, \tag{4.24}
\]
where
\[
A_{\pm\,\mu\nu} = \frac{[\pm 1 + \sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]}]g^{\beta}_{\mu}(\mu\rho) \mp 2\beta^2\mu\epsilon^{\alpha\lambda}(\mu\rho)\nabla_{\lambda}}{2M^2_\pm\sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]}},
A_1 = -(A_+ + A_-). \tag{4.25}
\]
The first term is the same as the contribution from the Einstein–Hilbert action linearized about the vacuum, and therefore, it does not propagate physical degrees of freedom in three dimensions. So, we have to look at the massive poles. From the calculation similar to that in deriving equation (4.20), we can show that the eigenvalue of the \(\epsilon\) term in \(A_\pm\) is \(\pm \sqrt{-4\beta\Lambda}\). We can thus evaluate the residues of the poles at \(M^2_\pm\) as follows:
\[
A_\pm \rightarrow \frac{\beta(\pm 1 \pm \sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]})}{M^2_\pm\sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]}}. \tag{4.26}
\]
The no-ghost condition from the residue at \(M^2_+\) gives
\[
\beta M^2_+ > 0. \tag{4.27}
\]
Since \((-1 + \sqrt{1 - 4\beta\mu^2[(12\alpha + 5\beta)\Lambda + \sigma]}\) is positive or negative depending on whether \(\beta\{(12\alpha + 5\beta)\Lambda + \sigma\} \) is negative or not, the condition from the pole residue at \(M^2_-\) gives \(\pm \beta M^2_- > 0\) according to \(\mp \beta\{(12\alpha + 5\beta)\Lambda + \sigma\} > 0\). On the other hand, the stability condition requires \(M^2_+ \geq 0\); so, (4.27) states that
\[
\beta > 0, \tag{4.28}
\]
and then, the lower sign is not allowed. Thus, we also have to have
\[
\beta M^2_- > 0, \tag{4.29}
\]
As \(\beta > 0\), the stability condition implies the unitarity of the theory under the second condition in (4.29). If the latter is not satisfied, the mode with mass \(M_-\) becomes ghost.
We now turn to the scalar part. The easiest way to see the spectrum for these fields is to take
the determinant of the kinetic term matrix and obtain the eigenvalues of the d’Alembertian.
We find that it is given by
\[
\frac{9}{(72)^2} a [ (3 - b) □ + 8Λ ] [ (8α + 3β) □ + 4(3α + β)Λ - σ ].
\] (4.30)
Consequently, there are two modes of mass squared \( \frac{8Λ}{b-3} \), which are gauge dependent, and
these cancel against the FP ghosts \( \hat{S} \) and \( \hat{\bar{S}} \). The remaining one is gauge invariant.

We still have to check how the propagator of each mode becomes. For this purpose, we
set \( b = 1/3 \) for simplicity. The relevant part of the action then gives
\[
L_S = \frac{1}{18} \left[ h - \frac{8α + 3β}{□ + 3Λ} \hat{η} \right] [ (8α + 3β) □ + 4(3α + β)Λ - σ ] [ □ + 3Λ ] \left[ h - \frac{8α + 3β}{□ + 3Λ} \hat{η} \right]
+ \frac{2}{9a} \hat{η}(□ + 3Λ)\hat{η}.
\] (4.31)
The propagator for \( \hat{h} \equiv \frac{1}{2} [ h - \frac{□}{□ + 3Λ} \hat{η} ] \) is given by
\[
1 \left[ (8α + 3β) □ + 4(3α + β)Λ - σ ] [ □ + 3Λ \right] = \frac{1}{(12α + 5β)Λ + σ} \left[ □ + 3Λ - \frac{8α + 3β}{□ + 3Λ} \right] (8α + 3β) □ + 4(3α + β)Λ - σ \] (4.32)
The first part and \( \hat{η} \) represent the modes cancelling against \( \hat{S} \) and \( \hat{\bar{S}} \), and the second part is the
mode we are left with. Thus, the unitarity condition is
\[
(12α + 5β)Λ + σ > 0.
\] (4.33)
The stability condition is
\[
\frac{σ - 4(3α + β)Λ}{8α + 3β} \geq 0 \quad \text{for AdS},
\]
\[
\frac{σ - 4(3α + β)Λ}{8α + 3β} \geq Λ \quad \text{for dS}.
\] (4.34)

We now note that the unitarity conditions for the tensor mode (4.29) and for the scalar
mode (4.33) are incompatible. This means that we can have either the tensor mode or the
scalar mode. Thus, we must have either
\[
8α + 3β = 0,
\] (4.35)
or
\[
β = 0 \quad \text{and} \quad μ \to \infty.
\] (4.36)
The first case corresponds to the decoupling of the scalar mode, whereas the second case to
the decoupling of the tensor mode. Let us discuss these cases in turn.

4.1. \( 8α + 3β = 0 \) case

This condition was taken as a starting point in [9], but this is only one of the cases where the
theory can be unitary. In this case, as we have seen above, \( \hat{η} \) and \( \hat{h} \) cancel against the FP ghosts
\( \hat{S} \) \( \text{and} \) \( \hat{\bar{S}} \) and we should concentrate on the tensor part of the action.

Let us now examine the stability condition of the theory for AdS and dS, separately.
4.1.1. AdS case. We first note that our conditions (4.27)–(4.29) confirm a conjecture in [12]; noting that the second condition in (4.29) is $\beta(\beta \Lambda + 2 \sigma) < 0$ and $\beta > 0$ in this case, the absence of tachyon implies the absence of ghost under the condition $\Omega \equiv -\frac{\beta \Lambda + 2 \sigma}{2 \beta \Lambda} < 0$ for $\Lambda < 0$ in the presence of the LCS term. As conjectured there, the ghost appears for $\Omega > 0$, though the AdS irreps may be unitary. Thus, the unitarity of the irreps is not enough to ensure the unitarity of the field theory, and we need the off-shell analysis like here, not just field equations, to see this. In the limit $\mu \to \infty$, $\beta M^2_{\pm} = \beta \Lambda / 2 - \sigma$, and (4.27) and (4.29) both give the same condition in agreement with [9].

Let us next consider the stability condition. Since $M^2_{\pm} > M^2_{\mp}$, only

$$M^2_{\mp} > 0$$

has to be satisfied. This leads to

$$1 + \beta M^2_{\mp}(\beta \Lambda - 2 \sigma) > \sqrt{1 - 2 \beta M^2_{\mp}(\beta \Lambda + 2 \sigma)}.$$  (4.37)

Under the condition that the left-hand side is positive,

$$\Lambda > \bar{\Lambda} \equiv -\frac{2 \beta M^2_{\mp} \sigma - 1}{\beta^2 \mu^2},$$  (4.38)

we can take the squares of both sides to obtain

$$4 \beta^2 M^2_{\mp} \Lambda + (\beta \Lambda - 2 \sigma)^2 > 0.$$  (4.39)

This gives the condition either

$$\Lambda > \Lambda_+, \quad \text{or} \quad \Lambda < \Lambda_-,$$  (4.40)

where we have defined

$$\Lambda_{\pm} \equiv -\frac{1}{2} - \frac{\beta M^2_{\mp} \mp \sqrt{1 - 2 \beta M^2_{\mp} \sigma}}{\beta^2 \mu^2} = -\left(\frac{1 \mp \sqrt{1 - 2 \beta M^2_{\mp} \sigma}}{\beta \mu}\right)^2,$$  (4.41)

both of which are negative. We also require (4.39). It turns out that $\bar{\Lambda} \geq \Lambda_-$. This excludes the second possibility in (4.40).

Now consider the case $\sigma = +1$. We must have $\Lambda > \max(\Lambda_+, \bar{\Lambda})$. The second condition in (4.29) states that

$$\Lambda < -\frac{2}{\beta}.$$  (4.42)

However, it is easy to show that this is incompatible with $\Lambda > \Lambda_+$. Thus, $\sigma = +1$ is excluded. Similarly, $\sigma = 0$ is not allowed.

We are left only with the possibility $\sigma = -1$. In this case, we find that $\Lambda_+ > \bar{\Lambda}$. So, finally, we arrive at the condition

$$\beta > 0, \quad \sigma = -1, \quad 0 > \Lambda > \Lambda_+,$$  (4.43)

together with arbitrary $\mu$. In the limit $\mu \to \infty$, this agrees with the condition in [9]. Our results generalize the condition to the more general case.

There is one possible subtlety here when one of the masses vanishes and becomes degenerate with the graviton. This occurs at the boundary of the stability condition:

$$\Lambda = \Lambda_{\pm}.$$  (4.44)

This case corresponds to what is known as the critical limit. In the limit $\beta \to 0$, we have

$$\Lambda_+ \to - (\mu \sigma)^2,$$  (4.45)

which is precisely the case discussed in [15] for $\sigma = +1$. There appear some additional logarithmic modes, which are complicated [19, 20], and it is argued that the theory is unitary [15].
4.1.2. $dS$ case. For $dS$, we should have
\[ M^2 > \Lambda. \]  
(4.47)

It follows that
\[ M^2 - \Lambda = \frac{1}{4\beta^2\mu^2}(1 - \sqrt{1 - 2\beta\mu^2(\beta\Lambda + 2\sigma)})^2 \]  
(4.48)
is positive definite; so, the stability condition is automatically satisfied. However, we have to impose conditions (4.22) and (4.29). Both are satisfied for
\[ \Lambda < -\frac{2\sigma}{\beta}, \]  
(4.49)
but then this states that $\sigma$ must be negative to allow for positive $\Lambda$. To summarize the conditions, we have
\[ \beta > 0, \quad \sigma = -1, \quad 0 < \Lambda < \frac{2}{\beta}. \]  
(4.50)
This result is in agreement with [9, 11].

4.2. $\beta = 0$ case

Let us now turn to the second possibility in (4.36), which was not considered in [9]. Since the tensor mode does not decouple if $\mu$ is finite, the LCS term should be absent here and the analysis is considerably simplified. We now consider the cases of AdS and dS in turn.

4.2.1. AdS case ($\Lambda < 0$). Here, we have to require only (4.33) and (4.34). First, for $\alpha > 0$, the conditions give
\[ -\frac{\sigma}{12\alpha} < \Lambda \leq \frac{\sigma}{12\alpha}. \]  
(4.51)
This is possible only for $\sigma = +1$. Then, the conditions are
\[ \alpha > 0, \quad -\frac{1}{12\alpha} < \Lambda < 0, \quad \sigma = +1. \]  
(4.52)
For $\alpha < 0$, we have
\[ \Lambda < -\frac{\sigma}{12\alpha} \quad \text{and} \quad \Lambda \leq \frac{\sigma}{12\alpha}. \]  
(4.53)
Here, $\sigma = \pm 1, 0$ may be all allowed. This is a new possibility compared with the Minkowski case. However, if we take the limit $\Lambda \to 0$, these conditions contradict each other and this case ceases to exist.

These results are in agreement with the previous result on Minkowski spacetime.

4.2.2. $dS$ case ($\Lambda > 0$). It follows from equations (4.33) and (4.34) that for $\alpha > 0$
\[ -\frac{\sigma}{12\alpha} < \Lambda \leq \frac{\sigma}{20\alpha}. \]  
(4.54)
This is possible only for $\sigma = +1$ to allow for positive $\Lambda$. The other case $\alpha < 0$ turns out to be inconsistent; so, this is the only possibility here.

To summarize the results of this section, we have unitary theory around the maximally symmetric spacetimes for the cases listed in table 2. In the limit $\Lambda \to 0$, all these results are consistent with the results for Minkowski spacetime in the previous section.
Table 2. Unitary theories around maximally symmetric spacetimes.

| $\alpha$, $\beta$ | $\Lambda$ | $\sigma$ | $\mu$ |
|------------------|---------|---------|-------|
| $-\frac{1}{3}\beta$, $\beta > 0$ | negative, $0 > \Lambda > \Lambda_+$ | $\sigma = -1$ | arbitrary |
| $-\frac{1}{3}\beta$, $\beta > 0$ | positive, $\frac{2}{3} > \Lambda > 0$ | $\sigma = -1$ | arbitrary |
| $\alpha > 0$, $\beta = 0$ | negative, $0 > \Lambda > -\frac{1}{12}$ | $\sigma = +1$ | $\mu = \infty$ |
| $\alpha < 0$, $\beta = 0$ | negative, equation (4.53) | all | $\mu = \infty$ |
| $\alpha > 0$, $\beta = 0$ | positive, $\frac{1}{3\alpha} > \Lambda > 0$ | $\sigma = +1$ | $\mu = \infty$ |

5. Criticality in 4D

It is straightforward to extend the calculation of the quadratic fluctuation around maximally symmetric spacetimes to $D$ dimensions. In four dimensions, the action (2.1) without the LCS term is the most general as the fourth-order action, since the Riemann tensor squared can be transformed into other terms using the fact that the Gauss–Bonnet combination is a total derivative. Since most of the analysis of criticality is done at the level of field equations, it may be of interest to see how this emerges from the Lagrangian approach. This provides some new view of the critical theory as to the ghost problem. Our following discussions are mainly for four dimensions, but we present the formulae valid for arbitrary dimensions as much as possible.

After some calculation keeping dimensions arbitrary, we find that the quadratic Lagrangian is given by

$$L_2 = -\frac{2}{D-2} \left[ \frac{2(Da + b)}{D} \Lambda + \frac{\sigma}{2} \right] h_{\mu\nu}^a G_{\mu\nu}(h) + \beta h_{\mu\nu}(h)^2 + \frac{4a + (4 - D)b}{(D - 2)^2} \left[ G_{\mu}^\mu(h) \right]^2, \quad (5.1)$$

where

$$G_{\mu\nu}(h) = \frac{1}{2} \left[ \nabla_{\mu} \nabla_{\nu} h - \nabla_{\mu} h_{\nu} - \nabla_{\nu} h_{\mu} + \Box h_{\mu\nu} + (\nabla_{\nu} h^\mu - \Box h) g_{\mu\nu} 
- \frac{4}{(D - 1)(D - 2)} \Lambda h_{\mu\nu} - \frac{2(D - 3)}{(D - 1)(D - 2)} \Lambda h g_{\mu\nu} \right]. \quad (5.2)$$

The condition that the maximally symmetric spacetime is a solution now becomes

$$\Lambda_0 = \sigma \Lambda + 2(Da + b) \frac{D - 4}{(D - 2)^2} \Lambda^2. \quad (5.3)$$

The parametrization (4.9) in general dimensions is

$$h_{\mu\nu} = h_{\mu\nu}^T + \nabla_{\mu} \xi_{\nu} + \nabla_{\nu} \xi_{\mu} + \nabla_{\mu} \nabla_{\nu} \eta - \frac{1}{D} \eta g_{\mu\nu} \Box \eta + \frac{1}{D} \overline{\eta} g_{\mu\nu} h; \quad (5.4)$$

with conditions on the fields similar to three dimensions. We find

$$G_{\mu\nu} = -\frac{1}{2} \left[ \left( \Box - \frac{4}{(D - 1)(D - 2)} \Lambda \right) h_{\mu\nu}^T - \frac{D - 2}{D} \nabla_{\mu} \nabla_{\nu} \Box \eta + \frac{D - 2}{D} \Box \left( \Box + \frac{2}{D - 2} \Lambda \right) \eta g_{\mu\nu} 
+ \frac{D - 2}{D} \nabla_{\mu} \nabla_{\nu} h - \frac{D - 2}{D} \left( \Box + \frac{2}{D - 2} \Lambda \right) h_{\mu\nu} \right]. \quad (5.5)$$
A straightforward calculation then yields

\[
L^2 = \frac{1}{4} h^{\mu\nu}_T \left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) \left[ \beta \left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) \right]
\]

\[
+ \frac{4}{D-2} \Lambda (D\alpha + \beta) + \sigma \right] h^{\mu\nu}_T
\]

\[
+ \frac{(D-1)(D-2)}{4D^2} \left[ \hat{\eta} \Delta \Box \hat{\eta} - 2h \Delta \sqrt{\Box + \frac{2D}{(D-1)(D-2)} \Lambda} \hat{\eta} \right]
\]

\[
+ h \Delta \left( \Box + \frac{2D}{(D-1)(D-2)} \Lambda \right) h \right] \right)
\]

(5.6)

where we have defined

\[
\hat{\eta} \equiv \sqrt{\Box + \frac{2D}{(D-1)(D-2)} \Lambda} \eta,
\]

\[
\Delta \equiv \frac{4(D-1)\alpha + D\beta}{D-2} - \frac{4(D-4)}{(D-2)^2} (D\alpha + \beta) \Lambda - \sigma.
\]

(5.7)

Our next task is to introduce the gauge fixing and the corresponding FP ghost terms. This procedure shows that we must have

\[
4(D-1)\alpha + D\beta = 0
\]

(5.8)
in order to decouple the scalar modes. As it happens, this is valid for arbitrary dimensions [18] though we did not include the Riemann tensor-squared term.

Now consider the propagator of $h^{\mu\nu}_T$ for $D = 4$:

\[
\frac{1}{\Box - \frac{4}{(D-1)(D-2)} \Lambda} \beta \left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) + \frac{1}{2(4\alpha + \beta) \Lambda + \sigma}
\]

\[
\times \left[ \beta \left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) + 2(4\alpha + \beta) \Lambda + \sigma \right]
\]

\[
= \frac{1}{2(4\alpha + \beta) \Lambda + \sigma} \beta \left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) + 2(4\alpha + \beta) \Lambda + \sigma
\]

(5.9)

We see that in general there are two modes in our quadratic action (5.6), and clearly, the propagators have residues with positive and negative values whatever the sign of the factor in front of the two propagators. If one chooses the positive sign for the massless mode from the Einstein theory, the other gives a mode of a negative norm. Since the Einstein mode propagates in four dimensions in contrast to 3, there is no way to make all physical modes have a positive norm. This makes a sharp contrast to three dimensions. However, it may appear that there is a possibility that they may cancel with each other if the massive mode becomes massless [17], eliminating ghost modes. This is the critical gravity discussed recently. The condition is given by

\[
\alpha = -\frac{\sigma}{2\Lambda},
\]

(5.10)
in agreement with the result in [17] for $\sigma = +1$. However, this naive argument for the absence of the ghost mode may not be true in four dimensions. Even though it looks that the contribution may be cancelled, actually this critical case introduces new degrees of freedom called log modes [19, 20]. This could be most easily seen if we go back to our action (5.6), which shows that the field equation simply becomes

\[
\left( \Box - \frac{4}{(D-1)(D-2)} \Lambda \right) h^{\mu\nu}_T = 0.
\]

(5.11)
This equation certainly contains solutions for the usual Einstein gravity and also additional modes which are not the solutions of the Einstein theory. In fact, there is some discussions on the ghost modes [21]. The question is then whether some boundary conditions can eliminate the ghosts and make the theory unitary. This subject deserves further study.

One very interesting feature of the above critical theory is that it can be written as Einstein plus Weyl squared and cosmological terms:

$$S = \frac{1}{\kappa^2} \int d^4x \sqrt{-g} \left[ R - 2\Lambda + \frac{3}{4\Lambda} C_{\mu\nu\lambda\rho}^2 \right]$$

up to the Gauss–Bonnet combination which is a total derivative in four dimensions, where $C_{\mu\nu\lambda\rho}$ is the Weyl tensor defined by

$$C_{\mu\nu\lambda\rho} = R_{\mu\nu\lambda\sigma} - (g_{\mu[\lambda} R_{\sigma]\nu] - g_{\nu[\lambda} R_{\sigma]\mu]) + \frac{1}{3} g_{\mu[\lambda} g_{\sigma]\nu]} R,$$

where the brackets stand for anti-symmetrization. To make the theory close to the Einstein, we should take $\sigma = +1$. It is known that the theory of similar structure appears in higher dimensional critical theories if one includes Riemann tensor squared and imposes the following conditions: (a) absence of scalar modes, (b) all massless modes and (c) unique vacuum [18]. The last condition is necessary because the equation determining $\Lambda$ in terms of the ‘bare’ cosmological constant $\Lambda_0$ becomes the quadratic equation, which has two solutions in general.

6. Discussions and conclusions

In this paper, we have studied that for what range of parameters, the gravity theory with higher derivative and topological mass terms can be unitary and stable in three dimensions, allowing all possible values for the coefficients. By examining the quadratic fluctuations around possible vacua in the Lagrangian, we obtain results summarized in table 1 for the Minkowski spacetime and in table 2 for maximally symmetric spacetimes. We have found that the unitarity of the AdS irreps is not enough to ensure the unitarity of the field theory. Making the off-shell analysis, we have been able to identify the conditions. We did this analysis for each of the vacuum separately. In [9], the unitarity condition around the maximally symmetric spacetimes was studied with the particular relation $8\alpha + 3\beta = 0$. However, it is more significant to study these conditions for each case separately without taking account of constraints from other vacua. Also, to the best of our knowledge, there have not been discussions around maximally symmetric spacetimes including the topological mass term in the Lagrangian approach. Considering these possibilities, we have identified all possible conditions for flat Minkowski and maximally symmetric spacetimes and found that there is a certain allowed parameter region that has not been explored.

It turns out that only the negative value for the sign of the Einstein term is allowed if the Ricci tensor-squared term is present. We have seen that without the Ricci tensor squared, the tensor modes decouple and the theory does not contain spin two modes, which may be of little interest as gravity theory. If the condition requires the negative sign for the Einstein term in the presence of the Ricci squared term also for higher dimensions, then this would mean that the low-energy approximation would be different from the Einstein theory. In analogy with the critical three-dimensional gravity, it has been argued that there is a possibility that the theory may be unitary with the usual sign of the Einstein term with the Ricci squared term [17]. We have seen that the possibility could be understood as a cancellation of the contribution of the mode of the negative norm with that of the positive norm in our approach. However, there arise logarithmic modes which may be problematic. If this mode could be eliminated by imposing suitable boundary conditions, it may give a sensible theory in the tree level, but the question remains if the theory is unitary and renormalizable at the quantum level.
When the critical condition is imposed, the theory becomes the Einstein theory with Weyl squared and cosmological terms with a special coefficient. This theory allows the solution in the Einstein theory, but also involves an additional solution. As argued recently in the cosmological context [26], certain boundary conditions may single out the solutions in the Einstein theory. Thus, the Einstein theory may emerge from this kind of higher order theory.

The theory with the Weyl squared term may be renormalizable in four dimensions, but it is not so in higher dimensions. In $D (\geq 4)$ dimensions, we may have to include $R_{\mu\nu} \left[ (D-1)/2 \right]$ terms, where $R$ stands for the curvature tensors and the square brackets for the Gauss symbol. It may be interesting to study what combinations may be allowed in higher dimensions if the critical conditions are imposed, and see if the theory may become renormalizable. It has been found that the allowed terms combine into Weyl squared when only the curvature-squared terms are considered and the theory is required to be critical [18]. Some study has been done in [23, 27], but more systematic analysis and determination of the general forms are desirable. Another interesting question is: What happens when dilaton, which always exists in superstring theories, is included?

We hope to return to these problems in the future.

Acknowledgments

We would like to thank Paul K Townsend for numerous valuable discussions and careful reading of the manuscript, and S Deser, A Ishibashi and B Tekin for very useful discussions. This work was supported in part by the Grant-in-Aid for Scientific Research Fund of the JSPS (C) nos 20540283, 21·09225 and (A) 22244030.

Appendix. Conventions and useful formulae

Here, we summarize our conventions and formulae necessary in the text. We give these such that they are valid for any dimension $D$.

Our signature of the metric is $(-, +, \ldots)$ and the curvature tensors are given as

$$R^\alpha_{\beta\mu\nu} = \partial_\mu \Gamma^\alpha_{\beta\nu} - \partial_\nu \Gamma^\alpha_{\beta\mu} + \Gamma^\alpha_{\mu\lambda} \Gamma^\lambda_{\beta\nu} - \Gamma^\alpha_{\nu\lambda} \Gamma^\lambda_{\beta\mu},$$

$$R_{\mu\nu} = R^\alpha_{\mu\alpha\nu}. \tag{A.1}$$

For the background, we take

$$\bar{G}_{\mu\nu} = -\Lambda \bar{g}_{\mu\nu}, \quad \bar{R}_{\mu\nu} = \frac{2}{D-2} \Lambda \bar{g}_{\mu\nu}, \quad \bar{R}_{\mu\nu\rho\lambda} = \frac{2}{(D-1)(D-2)} \Lambda (\bar{g}_{\mu\rho} \bar{g}_{\nu\lambda} - \bar{g}_{\mu\lambda} \bar{g}_{\nu\rho}). \tag{A.2}$$

Expansion around the background gives

$$\Gamma^\alpha_{\mu\nu} = \Gamma^\alpha_{\mu\nu} + \kappa \Gamma^\alpha_{\mu\nu}^{(1)} + \kappa^2 \Gamma^\alpha_{\mu\nu}^{(2)}, \tag{A.3}$$

where

$$\Gamma^\alpha_{\mu\nu}^{(1)} = \frac{1}{2} (\nabla_\nu h^\alpha_{\mu} + \nabla_\mu h^\alpha_{\nu} - \nabla^\alpha h_{\mu\nu}), \tag{A.4}$$

$$\Gamma^\alpha_{\mu\nu}^{(2)} = -\frac{1}{2} h^\alpha_{\beta\delta} (\nabla_\nu h_{\beta\mu} + \nabla_\mu h_{\nu\beta} - \nabla_\beta h_{\mu\nu}). \tag{A.5}$$

Note that

$$\sqrt{-g} = \sqrt{-\bar{g}} \left[ 1 + \frac{\kappa}{2} h + \frac{\kappa^2}{8} (h^2 - 2h_{\mu\nu}^2) + O(\kappa^3) \right]. \tag{A.6}$$
We find, to the second order,
\[ R^{(2)}_{\mu
u} = \tilde{R}^{(2)}_{\mu
u} + \kappa R^{(1)}_{\mu
u} + \kappa^2 R^{(2)}_{\mu
u}. \]

Similarly
\[ R^{(2)}_{\mu
u} = \frac{1}{2} \left( \nabla_\rho \nabla_\sigma h^\rho_{\mu
u} - \nabla_\rho h^\rho_{\mu\nu} + \nabla_\sigma h^\sigma_{\mu\nu} + \frac{1}{2} \tilde{R}^{\mu\nu}_\rho h^\rho_{\mu\nu} + \frac{1}{2} \tilde{R}^{\mu\nu}_\sigma h^\sigma_{\mu\nu} \right). \]  
(A.7)

\[ R^{(1)}_{\mu
u} = \nabla_\lambda h^\lambda_{\mu\nu} - \nabla_\mu h^\lambda_{\lambda\nu} - \nabla_\nu h^\lambda_{\mu\lambda} + \frac{2}{(D-1)(D-2)} \Lambda (Dh^\mu_{\mu\nu} - h\tilde{g}^\mu_{\mu\nu}), \]

\[ R^{(2)}_{\mu
u} = \frac{1}{2} \nabla_\lambda (h^\lambda_{\mu\nu} \nabla_\beta h^\beta_{\gamma\gamma} h^\gamma_{\mu\nu}) - \frac{1}{2} \partial_\beta [h^\beta_\mu (2h^\mu_{\gamma\gamma} - \nabla_\gamma h)] \]
\[- \frac{1}{2} \nabla_\beta (\nabla_\mu h^\beta_{\alpha\nu} - \nabla_\nu h^\beta_{\mu\alpha} + \nabla_\alpha h^\beta_{\mu\nu} + \frac{1}{4} \nabla_\mu h (2h^\mu_{\gamma} - \nabla^\gamma h) \]
\[ + \frac{1}{2} h^\gamma_{\beta\gamma} \nabla_\alpha h - \frac{1}{2} h^\gamma_{\alpha\gamma} \nabla_\beta h + \frac{1}{2} h_{\gamma\beta} (\nabla_\mu h^\gamma_{\beta\nu} + \nabla_\nu h^\gamma_{\mu\beta} - \nabla^\alpha h^\gamma_{\beta\mu}) + \frac{2}{(D-2)} \Lambda h_\beta h^\beta_{\mu\nu}. \]
(A.8)

where \( \Box = \nabla_\mu \nabla^\mu \). When the total derivative terms are dropped, \( R^{(2)} \) makes the contribution to the action
\[ R^{(2)} \quad \simeq \frac{1}{4} \left( h_{\mu\nu} \Box h^{\mu\nu} + h \Box h \right) + \frac{1}{2} \frac{\Lambda h^2}{(D-1)(D-2)} \Lambda h^2 + \frac{1}{2} h^2. \]  
(A.9)

We use the notation \( \simeq \) to denote the equality up to total derivatives. We also have
\[ \tilde{g}^{\mu\nu} R^{(1)}_{\mu\nu} = \nabla_\mu h^\mu - \Box h, \]
\[ h^{\mu\nu} R^{(1)}_{\mu\nu} \quad \simeq - \frac{1}{2} (h \nabla_\mu h^{\mu\nu} + h_{\mu\nu} \Box h^{\mu\nu}) - \frac{1}{2} \frac{\Lambda h^2}{(D-1)(D-2)} \Lambda (Dh^2_{\mu\nu} - h^2), \]  
(A.10)

\[ \tilde{g}^{\mu\nu} R^{(2)}_{\mu\nu} = \frac{1}{2} h^{\mu\nu} \left( \tilde{G}_{\mu\nu} + \frac{2}{(D-2)} \Lambda h_{\mu\nu} - \frac{1}{(D-2)} \Lambda h \tilde{g}_{\mu\nu} \right). \]

Note that \( \tilde{g}^{\mu\nu} R^{(1)}_{\mu\nu} \neq R^{(1)} \), because the latter has the additional contribution from \( h^{\mu\nu} \tilde{R}_{\mu\nu} \).
