Abstract

Nesterov’s accelerated gradient methods (AGM) have been successfully applied in many machine learning areas. However, their empirical performance on training max-margin models has been inferior to existing specialized solvers. In this paper, we first extend AGM to strongly convex and composite objective functions with Bregman style prox-functions. Our unifying framework covers both the ∞-memory and 1-memory styles of AGM, tunes the Lipschitz constant adaptively, and bounds the duality gap. Then we demonstrate various ways to apply this framework of methods to a wide range of machine learning problems. Emphasis will be given on their rate of convergence and how to efficiently compute the gradient and optimize the models. The experimental results show that with our extensions AGM outperforms state-of-the-art solvers on max-margin models.

1. Introduction

There has been an explosive interest in machine learning over the past decade, much of which has been fueled by the phenomenal success of binary Support Vector Machines (SVMs). Driven by numerous applications, recently, there has been increasing interest in support vector learning with linear models. At the heart of SVMs is the following regularized risk minimization (RRM) problem:

\[ \min_{w} J(w) := \lambda \Omega(w) + R_{\text{emp}}(w) \]  

where \([x]_+ = x\) if \(x \geq 0\) and 0 otherwise. Here we assume access to a training set of \(n\) labeled examples \(\{(x_i, y_i)\}_{i=1}^n\) where \(x_i \in \mathbb{R}^p\) and \(y_i \in \{-1, +1\}\), and use the half square Euclidean norm \(\|w\|_2^2 = \sum_i w_i^2\) as the regularizer. The parameter \(\lambda\) controls the trade-off between the empirical risk and the regularizer.

There has been significant research devoted to developing specialized optimizers which minimize \(J(w)\) efficiently. Zhang et al. \cite{1} proved that cutting plane and bundle methods may require at least \(O(np/\epsilon)\) computational efforts to find an \(\epsilon\) accurate solution to (1), and they suggested using Nesterov’s accelerated gradient method (AGM) which provably costs \(O(np/\sqrt{\epsilon})\) time complexity. In general, AGM takes \(O(1/\sqrt{\epsilon})\) times of gradient query to find an \(\epsilon\) accurate solution to

\[ \min_{x \in Q} f(x), \]
Regularized Risk Minimization by Nesterov’s Accelerated Gradient Methods

[4], it does not compare favorably to existing specialized optimizers when applied to training large margin models [5]. It turns out that special structures exist in those problems, and to make full use of AGM, one must utilize the computational and statistical properties of the learning problem by properly reformulating the objectives and tailoring the optimizers accordingly.

To this end, our first contribution is to show that in both theory and practice smoothing $R_{\text{emp}}(\mathbf{w})$ as in [6] is advantageous to the primal-dual versions of AGM. The dual of (1) is

$$
\max_{\mathbf{\alpha}} D(\mathbf{\alpha}) = \sum_i \alpha_i - \frac{1}{2\lambda} \mathbf{\alpha}^T \mathbf{X} \mathbf{X}^T \mathbf{X} \mathbf{\alpha}, \quad (5)
$$

$$
s.t. \quad \mathbf{\alpha} \in \mathbb{Q}_2 := \left\{ \mathbf{\alpha} \in [0, n^{-1}]^n : \sum_i y_i \alpha_i = 0 \right\}. \quad (6)
$$

Comparing (4) with (1) and (5), it seems more natural to apply AGM to (5) because it is smooth. However in practice, most $\alpha_i$ at the optimum will be on the boundary of $[0, n^{-1}]$. According to [7], such $\alpha_i$’s are easy to identify and so the corresponding entries in the gradient are wasted by AGM. This structure of support vector is unique for max-margin models, which will also be manifested in our experiments (Section 6).

In contrast, smoothing $R_{\text{emp}}$ has a lot of advantages. First, it directly optimizes in the primal $J$, avoiding the indirect translation from the dual solution to the primal. Second, the resulting optimization problem is unconstrained. If $\Omega$ is strongly convex, then linear convergence can be achieved. Third, gradient of the smoothed $R_{\text{emp}}$ can often be computed efficiently, and details will be given in Section 5. Fourth, the diameter of the dual space $\mathbb{Q}_2$ often grows slowly with $n$, or even decreases. This allows using a loose smoothing parameter. Fifth, in practice most $\alpha_i$ at the optimum are 0, where $R_{\text{emp}}$ best approximates $R_{\text{emp}}$. Therefore, the approximation is actually much tighter than the worst case theoretical bound, and a good solution for $R_{\text{emp}}$ is more likely to optimize $R_{\text{emp}}$ too. Last but most important, the smoothed $R_{\text{emp}}$ themselves are reasonable risk measures [8], which also deliver good generalization performance in statistics. Now that it is much easier to optimize the smoothed objectives, a model which generalizes well can be quickly obtained with the homotopy scheme (i.e. anneal the smoothing parameter).

Using the same idea of smoothing $R_{\text{emp}}$, AGM can be applied to a much wider variety of RRM problems by utilizing its composite structure. Given a model $\psi$ of $R$, if $\Omega(\mathbf{w}) + \psi(\mathbf{w})$ can be solved efficiently, then [9] showed that $\Omega(\mathbf{w}) + R(\mathbf{w})$ can be solved in $O(1/\sqrt{\epsilon})$ steps, even if $\Omega$ is not differentiable, e.g. $L_1$ norm [10].

Similar approach is applied to the $L_{1,\infty}$ regularizer and the elastic net [11] regularizer by [12]:

$$
\Omega(\mathbf{w}) = \frac{\gamma}{2} ||\mathbf{w}||^2_2 + ||\mathbf{w}||_1 = \frac{\gamma}{2} \sum_i w_i^2 + \sum_i |w_i|. \quad (7)
$$

This $\Omega$ is strongly convex with respect to (wrt) the $L_2$ norm, and similarly in many RRM problems $\Omega$ is strongly convex wrt some norm $||.||$. For example, the relative entropy regularizer in boosting [13]:

$$
\Omega(\mathbf{w}) = \sum_i w_i \log w_i \quad (8)
$$

is strongly convex wrt the Frobenius norm. By exploiting the strong convexity, [17] accelerated the convergence rate from $O(1/\sqrt{\epsilon})$ to $O(\log \frac{1}{\epsilon})$. However, the prox-function in this case must be strongly convex wrt $||.||$ too. Existing methods either ignore the strong convexity in $\Omega$ [9], or restrict the norm to $L_2$ [10, 17]. As one major contribution of this paper, we extend AGM to exploit this strong convexity in the context of Bregman divergence. In particular, we allow $\Omega$ to be strongly convex wrt a Bregman divergence induced by a smooth convex function $d$ (to be formalized later), where $d$ is in turn strongly convex wrt certain norm $||.||$. By using $d$ as a prox-function, we manage to achieve linear convergence for a wide range of RRM problems.

There are two types of first order methods that both achieve the optimal rate. The first type is the original AGM pioneered by Nesterov [6, 17–20], which uses a sequence of estimation functions (hence we call it AGM-EF). In particular, it uses the whole past iterates to progressively build a sequence of estimate functions which approximate the objective function. The second type was developed by a number of other researchers and a unified treatment was given by [9]. Intuitively, it generalizes the idea of gradient descent by proximal regularization (hence we call it AGM-PR), which can be further accelerated by momentum. Therefore, these two types of methods are different in concept. In addition, both AGM-EF and AGM-PR a $\infty$-memory version which builds a model of the objective by using all the past gradients, and a 1-memory version which approximates that model by a single Bregman divergence.

We choose to base our extensions on AGM-EF, because compared with AGM-PR it provides much more
Then we can define
\[ \frac{1}{2} \| x - y \|_2^2 - \langle \nabla f(x), y - x \rangle. \]

By the definition of \(\sigma\)-sc, we have
\[ \Delta_d(x, y) \geq \frac{\sigma}{2} \| x - y \|_2^2, \quad \text{for all } x, y. \]

Furthermore, Bregman divergence can be used to generalize the concept of strong convexity [24, Definition 3, Chapter 4].

# 2. Preliminaries

From the optimization perspective, the objectives considered in this paper have the same form as in [9]. Let \(\mathbb{R}^p\) be endowed with a norm \(\| \cdot \|\). Consider the following nonsmooth convex objective:
\[
\min_{x} J(x) = f(x) + \Psi(x), \quad (10)
\]

where \(\Psi : \mathbb{R}^p \mapsto \mathbb{R} := (-\infty, +\infty)\) and \(f : \mathbb{R}^p \mapsto \mathbb{R}\) are proper, lower semicontinuous (lsc) and convex. Assume dom \(\Psi\) is closed, \(f\) is differentiable on an open set containing dom \(\Psi\), and \(\nabla f\) is Lipschitz continuous on dom \(\Psi\), i.e. there exists \(L > 0\) such that
\[
\| \nabla f(x) - \nabla f(y) \|^* \leq L \| x - y \|, \quad x, y \in \text{dom } \Psi.
\]

Some special cases are in order. The first is constrained smooth optimization, where \(\Psi\) is the indicator function for a nonempty closed convex set \(Q \subseteq \mathbb{R}^p\):
\[
\Psi(x) = \begin{cases} 
0 & \text{if } x \in Q \\
+\infty & \text{otherwise}
\end{cases}.
\]

Therefore, in the sequel we will always discuss unconstrained minimization for \(J(w)\), although this is just a matter of notation. A second example is the \(L_1\) regularization, where
\[
\Psi(x) = \sum_{i=1}^{p} |x_i|.
\]

In fact, many machine learning problems are special cases of (10) and details can be found in Section 5 and [25, Table 5].

Next, we will present in detail two additional assumptions: strong convexity of \(f\) and \(\Psi\) in the sense of Bregman divergence, and efficiently solvable local optimization problems.

## 2.1. Extending strong convexity to Bregman divergence

Let \(d\) be a differentiable and \(\sigma\) strongly convex function with respect to some norm \(\| \cdot \|\). Then we can define a Bregman divergence:
\[
\Delta_d(x, y) = d(x) - d(y) - \langle \nabla d(y), x - y \rangle.
\]

| Flexibility in adaptively tuning \(L\). This is because the inductive relationship maintained by AGM-EF involves a single iteration, while that for AGM-PR involves two successive steps. The novelty and generality of our method in the context of existing methods are summarized in Table 1. We further provide bounds on the duality gap which amounts to effective termination criteria. As another important contribution, we derive linear convergence for the duality gap in the context of strong convexity. Computationally, at each iteration our method requires only one projection and one gradient evaluation within the feasible region.2 |

Table 1. Summary of AGM-EF. “sc” means strongly convex and “cvx” means just convex. × means novel contribution of this paper. AGM-PR can handle all but sc.

Outline of the paper. In Section 2, we follow [24, Section 4.1, Definition 3] to extend the concept of strong convexity to the context of Bregman divergence. We show several properties that will play a key role in the subsequent development of the new algorithms. In Section 3 and 4, two novel variants of AGM-EF are developed along the lines of ∞-memory and 1-memory. They both achieve global linear convergence by utilizing the Bregman generalized strong convexity in either \(\Omega\) or \(R_{\text{emp}}\). Section 5 elaborates on how to effectively apply our method to solve Bregman regularized risk minimization problems, and many examples of machine learning models are discussed. Also presented is the algorithms which efficiently compute the gradient and solve the model. Experimental results are given in Section 6, where we show empirically that by smoothing \(R_{\text{emp}}\) and exploiting the generalized strong convexity in \(\Omega\), the \(L_2\) and entropic regularized risk minimization problems can be solved significantly faster than the state-of-the-art optimizers.

A ready reckoner of the convex analysis concepts used in the paper can be found in Appendix A.

1All APM-PR variants with adaptive \(L\), e.g. [9, 10, 21, 22], require the estimate of \(L\) grow monotonically through iterations. And their technique does not extend to asymmetric Bregman divergence.

2Some AGM algorithms require two projections [6] or two gradients [17] per iteration, or evaluate the gradient outside the feasible region [19, Section 2.2.4].

3AGM capitalizes on two properties of the norm: convexity and linearity (\(|c \cdot x| = |c| \|x\|\)).
Definition 1 (Strong convexity for Bregman divergence). A convex function $f$ is said to be $\lambda$ strongly convex with respect to $d$ ($\lambda$-sc wrt $d$) with $\lambda \geq 0$ if for all $x$ and $y$ we have

$$f(x) \geq f(y) + \langle g, x - y \rangle + \lambda \Delta_d(x, y) \quad \forall g \in \partial f(y).$$

If $\lambda > 0$, we say $f$ is strictly strongly convex.

For example, with $d(x) = \frac{1}{2} \|x\|^2$ where the norm is Euclidean, we recover the conventional strong convexity. Here we allow $\lambda$ to be 0 for a unified exposition, and trivially all convex functions are 0-sc wrt any $d$. It is noteworthy that Definition 1 preserves some important properties of the conventional strong convexity.

Property 1. If $f$ is $\lambda$-sc wrt $d$, then $f$ must be $\lambda \sigma$-sc wrt $\|\cdot\|$. Hence for any $\alpha \in [0, 1]$ and $x, y$, we have

$$f(\alpha x + (1 - \alpha)y) \leq \alpha f(x) + (1 - \alpha)f(y)$$

$$-\frac{\lambda}{2} \alpha (1 - \alpha) \|x - y\|^2.$$

Property 2. If $\alpha_i \geq 0$ and $f_i$ is $\lambda_i$-sc wrt $d$ ($\lambda_i \geq 0$), then $\sum_i \alpha_i f_i$ is a $\lambda_i$-sc wrt $d$.

Property 3. $d(x)$ is 1-sc wrt $d$. So by Property 2, $\Delta_d(x, x_0)$ is also 1-sc wrt $d$ for any fixed $x_0$.

Many problems are constrained to a feasible region $Q$. In the sequel we will always assume that $Q \subseteq \text{dom } d$ and $Q$ is closed and convex.

Property 4. Suppose $f : \mathbb{R}^n \to \mathbb{R}$ is proper, lsc, and $\lambda$-sc wrt $d$ and $x^* = \text{argmin}_x f(x)$. Then

$$f(x) - f(x^*) \geq \lambda \Delta_d(x, x^*) \quad \text{for all } x \in \text{dom } f.$$

The proof simply uses the definition of $\lambda$-sc and the optimality condition of $x^*$: $\langle g, x - x^* \rangle \geq 0$ for all $g \in \partial f(x^*)$ and $x \in \text{dom } f$.

A direct application of Property 2, 3 and 4 gives a very important inequality which is also used extensively in [9, Property 1] and [26, Lemma 6].

Property 5. Suppose $f$ is proper, lsc, and convex with range $\mathbb{R}$. Let $x^* = \text{argmax}_x f(x) + \Delta_d(x, x_0)$, then for all $x$

$$f(x) + \Delta_d(x, x_0) \geq f(x^*) + \Delta_d(x^*, x_0) + \Delta_d(x, x^*).$$

The following property of Bregman divergence plays a key role in keeping a compact expression of our estimation functions.

Property 6. For all $x_i \geq 0$ and $x_i \in \text{interior of } \text{dom } d$, define

$$q(x) := \langle s, x \rangle + \sum_i \alpha_i \Delta_d(x, x_i).$$

Then $q(x)$ can be equivalent expressed as

$$q(x) = a \Delta_d(x, x^*) + b,$$

where $a = \sum_i \alpha_i$, $x^* = \text{argmin}_x q(x)$, and $b = q(x^*)$. Note $x^*$ is the unconstrained minimizer of $q(x)$.

Proof. By the optimality condition of $x^*$ we have

$$\left\langle s + \sum_i \alpha_i (\nabla d(x^*) - \nabla d(x_i)), x - x^* \right\rangle = 0 \quad \forall x. \quad (11)$$

This equality must be changed to $\geq$ if $x^*$ is the minimizer of $q(x)$ over a constrained set $Q \subseteq \text{dom } d$. By definition,

$$q(x^*) = \langle s, x^* \rangle + \sum_i \alpha_i \Delta_d(x^*, x_i).$$

Subtracting it from the definition of $q(x)$ we get

$$q(x) = q(x^*) + \langle s, x - x^* \rangle + \sum_i \alpha_i \Delta_d(x^*)$$

$$= q(x^*) - \left\langle \sum_i \alpha_i (\nabla d(x^*) - \nabla d(x_i)), x - x^* \right\rangle$$

$$+ \sum_i \alpha_i \Delta_d(x) - \Delta_d(x_i) - (\nabla d(x_i), x - x^*))$$

$$= q(x^*) + \left(\sum_i \alpha_i \right) \Delta_d(x, x^*). \quad \square$$

Assumption 1. In the objective (10), we will assume that $f$ is $\lambda_1$-sc and $\Psi$ is $\lambda_2$-sc wrt a given $d$ ($\lambda_1, \lambda_2 \geq 0$). Then $f + \Psi$ is $\lambda$-sc, where

$$\lambda := \lambda_1 + \lambda_2.$$

2.2. Assumption on the ground optimization problem

We assume it is possible to efficiently solve the following ground problem:

Assumption 2. Given an arbitrary linear function $(u, x)$, $\alpha_i \geq 0$ and $x_i \in \text{dom } \Psi$ ($i \in [k] := \{1, \ldots, k\}$), assume the following optimization problem can be solved efficiently:

$$\min_{x} \langle u, x \rangle + b + \sum_{i=1}^{k} \alpha_i \Delta_d(x, x_i) + \Psi(x). \quad (12)$$

For different $k$, we call the assumption BD-$k$.

In [18] and [19], the 1-memory AGM-EF for general convex objective assumes BD-1. In [6] and [17], BD-$\infty$ is assumed in the sense that for arbitrary $k < \infty$, (12)
Regularized Risk Minimization by Nesterov’s Accelerated Gradient Methods

is assumed to be efficiently solvable. In our later 1-memory AGM-EF, we will assume BD-2 if 1 > 0. Although most literature assume BD-1, it is actually not hard to see that extension to BD-2 does not cause any real difficulty. In fact, even BD-∞ is feasible as long as \( \sum_{i} \alpha_i \nabla d(x_i) \) can be aggregated efficiently (which is often true).

As a direct consequence of BD-1, now that the \( f \) in (10) is \( 1 \)-sc and \( L \)-l.c.g, \( J(x) \) can be solved in one step if \( L = \sigma \lambda_1 \). To see this, by definition for all \( x \)

\[
  f(x) \leq f(x_0) + \langle \nabla f(x_0), x - x_0 \rangle + \frac{L}{2} \| x - x_0 \|^2,
\]

and

\[
  f(x) \geq f(x_0) + \langle \nabla f(x_0), x - x_0 \rangle + \lambda_1 \Delta_d(x, x_0)
  \geq f(x_0) + \langle \nabla f(x_0), x - x_0 \rangle + \frac{\lambda_1 \sigma}{2} \| x - x_0 \|^2.
\]

So clearly \( L \geq \sigma \lambda_1 \). If \( L = \sigma \lambda_1 \), then

\[
  f(x) = f(x_0) + \langle \nabla f(x_0), x - x_0 \rangle + \lambda_1 \Delta_d(x, x_0).
\]

Hence, \( f(x) + \Psi(x) \) exactly satisfies the precondition of BD-1. Therefore, in the sequel we will assume

\[
  L > \sigma \lambda_1.
\]

\( c := \frac{1}{\sigma \lambda_1} \) can be viewed as the condition number.

BD-2 allows us to inductively apply Property 6 to simplify the expression of the following function

\[
  q_n(x) := a_0 \Delta_d(x, x_0) + \sum_{i=1}^{n} [b_i + \langle u_i, x \rangle + a_i \Delta_d(x, x_i)]
\]

into

\[
  q_n(x) = \left( \sum_{i=0}^{n} a_i \right) \Delta_d(x, x_n) + q_n(x_n), \quad n \geq 1
\]

where \( x_n^* = \arg\min_{x} q_n(x) \). Let \( q_0(x) = a_0 \Delta_d(x, x_0) \). Then simplify \( q_1(x) \) into the sum of a constant and a Bregman divergence by Property 6:

\[
  g_1(x) = (a_0 + a_1) \Delta_d(x, x_1^*), \quad x_1^* = \arg\min_{x} q_0(x) + b_1 + \langle u_1, x \rangle + a_1 \Delta_d(x, x_1),
\]

since \( x_1^* \) can be computed efficiently according to assumption BD-2. Next, \( g_2(x) \) can be simplified by using (13) and Property 6 again:

\[
  g_2(x) = (a_0 + a_1) \Delta_d(x, x_2^*) + q_2(x_2),
\]

where \( x_2^* = \arg\min_{x} g_1(x) + b_2 + \langle u_2, x \rangle + a_2 \Delta_d(x, x_2) \).

This incremental scheme is especially useful when the \( \arg\min \) of all \( q_k(x) \) is readily available, [e.g. 23, Section 5].

**Notations.** Lower bold case letters (e.g., \( \mathbf{x}, \alpha \)) denote vectors, \( x_i \) denotes the \( i \)-th component of \( x \), \( \mathbf{0} \) refers to the vector with all zero components, \( e_i \) is the \( i \)-th coordinate vector (all 0’s except 1 at the \( i \)-th coordinate) and \( S_n \) refers to the \( n \) dimensional simplex \( \{ x \in [0, 1]^n : \sum_{i=1}^{n} x_i = 1 \} \). Unless specified otherwise, \( \langle \cdot, \cdot \rangle \) denotes the Euclidean dot product \( \langle x, w \rangle = \sum_i x_i w_i \). We denote \( \mathbb{R} := \mathbb{R} \cup \{ \infty \} \), and \( \{ t \} := \{ 1, \ldots, t \} \). From now on, we will always fix the \( d \) in the context and omit the subscript \( d \) in \( \Delta_d \).

We follow the definition of norms in [6] which we recap here. Suppose a finite dimensional real vector space \( E \) (e.g. \( \mathbb{R}^p \)) is endowed with a norm \( \| \cdot \| \). The space of linear functions on \( E \) is called the dual space which we denote as \( E^* \). The norm of \( E^* \) is defined as

\[
  \| s \|^* := \max_{x \in E : \| x \|_1 = 1} \langle s, x \rangle.
\]

Suppose \( A \) is a linear operator from \( E_1 \) to \( E_2^* \), and \( E_1 \) has norm \( \| \cdot \|_1 \) for \( i = 1, 2 \). Then the norm of \( A \) is defined as

\[
  \| A \| := \max_{x \in E_1, \alpha \in E_2, \| x \|_1 = \| \alpha \|_2 = 1} \langle A \alpha, x \rangle. \quad (14)
\]

If we define an adjoint operator \( A^* : E_2 \to E_1^* \) as

\[
  \langle A^* \alpha, x \rangle := \langle A \alpha, x \rangle, \quad \forall \alpha \in E_1, \alpha \in E_2.
\]

Then it can be shown that

\[
  \| A^* \| = \max_{x \in E_1, \alpha \in E_2, \| x \|_1 = \| \alpha \|_2 = 1} \langle A^* \alpha, x \rangle
  = \max_{x \in E_1, \alpha \in E_2, \| x \|_1 = \| \alpha \|_2 = 1} \langle A \alpha, x \rangle = \| A \|.
\]

The definition of matrix norm in (14) implies that

\[
  \| A \| \leq \| A^* \| \| \alpha \| \quad \forall \alpha \in E_1,
  \| A^* \| \leq \| A \| \| \alpha \| \quad \forall \alpha \in E_2.
\]

To simplify notation we denote

\[
  \ell_f(x; y, \lambda_1) := f(y) + \langle \nabla f(y), x - y \rangle + \lambda_1 \Delta(x, y).
\]

If \( f \) is \( 1 \)-sc, then \( \ell_f(x; y, \lambda_1) \leq f(x) \) for all \( y \) and \( x \).

3. \( \infty \)-memory AGM-EF

The \( \infty \)-memory version of AGM-EF refers to the class of algorithms which use in each iteration all the past gradients \( \nabla f(u_1), \ldots, \nabla f(u_k) \). We present the method in Algorithm 1.

\footnote{One can verify by simple algebra that \( u_{k+1} \) is a convex combination of \( z_k \) and \( x_k \).}
Regularized Risk Minimization by Nesterov’s Accelerated Gradient Methods

**Algorithm 1** \(\infty\)-memory AGM-EF (AGM-EF-\(\infty\)).

1. Arbitrarily initialize \(x_0 \in \text{dom } \Psi\). Set \(x_0 \leftarrow x_0\).
2. Set \(A_0 \leftarrow 0\).
3. \(\psi_0(x) \leftarrow \Delta(x, x_0)\).
4. for \(k = 0, 1, \ldots\) do
5. Denote as \(a_{k+1}\) the positive root (in \(a\)) of \((a + A(k)\lambda + A(k+1)\lambda + 1) + a_{k+1}A = A\sigma^{-1}A^2\).
6. \(A_{k+1} \leftarrow A_k + a_{k+1}\).
7. \(\tau_1 \leftarrow 1 + \lambda A_k, \tau_2 \leftarrow \lambda_1 a_{k+1}, \tau_3 \leftarrow 2 + A(k+1)\lambda + a_{k+1}\).
8. \(u_{k+1} \leftarrow \frac{a_{k+1} \tau_1 \tau_2 + (\tau A_k + \tau_2 a_{k+1}) x_k}{\lambda \tau_1 + \tau_2 + \tau_3}\).
9. \(\psi_{k+1}(x) \leftarrow \psi_k(x) + a_{k+1} [\Psi(x) + 1\ell_f(x; u_{k+1}, \lambda_1)]\).
10. Find \(z_{k+1} \leftarrow \arg:\min_x \psi_{k+1}(x)\).
11. \(x_{k+1} \leftarrow (A_k x_k + a_{k+1} z_{k+1}) / A_{k+1}\).
12. end for.

The main idea of the algorithm is to approximate \(J(x)\) by a sequence of functions \(\psi_k\) that are constructed in Step 8 of Algorithm 1, and then ensure the following relationship at all iterations \((k \geq 0)\):

\[
A_k J(x_k) \leq \min_x \psi_k(x) \tag{15}
\]

By construction, for all \(k \geq 0\)

\[
\psi_k(x) = \Delta(x, x_0) + \sum_{i=1}^k a_i [\Psi(x) + 1\ell_f(x; u_i, \lambda_1)] \tag{16}
\]

Summation from 1 to 0 is assumed to be 0. Now it is not hard to see that relationship (15) implies rates of convergence:

**Lemma 3.** If (15) holds for all \(k \geq 1\), then for any \(x \in \text{dom } \Psi\), we have

\[
J(x_k) - J(x) \leq A_k^{-1} \Delta(x, x_0) \tag{17}
\]

**Proof.** By (16), we have for all \(k \geq 1\)

\[
\psi_k(x) = \Delta(x, x_0) + \sum_{i=1}^k a_i [\Psi(x) + 1\ell_f(x; u_i, \lambda_1)] \\
\leq \Delta(x, x_0) + \sum_{i=1}^k a_i [\Psi(x) + 1\ell_f(x)] \\
= \Delta(x, x_0) + A_k J(x).
\]

Combining with (15), we get (17). \(\blacksquare\)

Therefore, the rate of convergence totally depends on how fast \(A_k\) grows. We will show that Algorithm 1 yields \(A_k \sim k^2\) if \(\lambda = 0\), or \(A_k \sim e^k\) if \(\lambda > 0\). All updates are also kept efficient. We next prove (15) and lower bound the growth rate of \(A_k\).

**Lemma 4** (Eq (15)). The sequence \(\{x_k\}\) generated by Algorithm 1 satisfy for all \(k \geq 0\)

\[
A_k J(x_k) \leq \min_x \psi_k(x) \tag{16}
\]

**Proof.** We prove by induction. First check both sides are 0 for \(k = 0\). Now suppose (15) holds for some step \(k \geq 0\). By (16) and Property 2, \(\psi_k\) must be \((\lambda A_k+1)\)-sc wrt \(d\). So by Property 4 and the fact that \(z_k\) minimizes \(\psi_k\), we have

\[
\psi_k(z_{k+1}) \geq \psi_k(z_k) + (\lambda A_k + 1) \Delta(z_{k+1}, z_k) \geq A_k J(x_k) + (\lambda A_k + 1) \Delta(z_{k+1}, z_k),
\]

where the second inequality is by induction assumption. So

\[
\min_x \psi_{k+1}(x) = \psi_{k+1}(z_{k+1}) = \psi_k(z_{k+1}) + a_{k+1} \ell_f(z_{k+1}, u_{k+1}, \lambda) + a_{k+1} \Psi(z_{k+1})
\]

\[
J(x_k) - J(x) \leq A_k^{-1} \Delta(x, x_0).
\]
Regularized Risk Minimization by Nesterov’s Accelerated Gradient Methods

\[ + \langle \nabla f(u_{k+1}), x_{k+1} - u_{k+1} \rangle + \frac{L}{2} \| x_{k+1} - u_{k+1} \|^2 \]
\[
(\sigma) \geq A_{k+1} \Psi(x_{k+1}) + A_{k+1} f(x_{k+1}) = A_{k+1} J(x_{k+1}).
\]

Here, step (a) is by (18), (b) is by the convexity of \( f \) at \( u_{k+1} \), (c) is by the \( \lambda_2 \)-sc of \( \Psi \) and Property 1. (d) is by the convexity and linearity of \( \| \cdot \| \). (e) is by the rule of choosing \( a_{k+1} \) in Step 5 of Algorithm 1. (f) is by the definition of \( x_{k+1} \) and \( u_{k+1} \). (g) is by \( L \)-t.c.g of \( f \).

Next, we can lower bound the growth rate of \( A_k \).

**Lemma 5.** Let \( k \geq 1 \). Then
\[
A_k \geq \max \left\{ \frac{\sigma}{4L} (k+1)^2, \frac{\sigma}{L - \sigma \lambda_1} \left( 1 + \sqrt{\frac{\sigma \lambda}{4L}} \right)^{2k-2} \right\}.
\]

**Proof.** Since \( A_0 = 0 \), so by solving Step 5 in Algorithm 1, we get \( A_1 = \frac{L}{\sigma} \). Hence the lemma clearly holds for \( k = 1 \). For all \( k \geq 1 \), denote
\[
M = (a_{k+1} + A_k)(\lambda_1 a_{k+1} + \lambda A_{k+1} + 1) + a_{k+1} \lambda_2 A_k
\]
\[
= A_{k+1} + \lambda A_k A_{k+1} + \lambda_1 a_{k+1} A_{k+1} + \lambda_2 a_{k+1} A_{k+1}.
\]

By the choice of \( a_{k+1} \) in Step 5 of Algorithm 1, we get
\[
A_{k+1} \leq M = \frac{L}{\sigma} (A_{k+1} - A_k)^2
\]
\[
= \frac{L}{\sigma} \left( \sqrt{A_{k+1}^2 + A_k^2} \right)^2 \left( \sqrt{A_{k+1}^2 - A_k^2} \right)^2
\]
\[
\leq \frac{4L}{\sigma} A_{k+1} \left( \sqrt{A_{k+1}^2 - A_k^2} \right)^2.
\]

So when \( \lambda = 0 \) we have
\[
A_k \geq \left( \frac{k-1}{2} \sqrt{\frac{\sigma}{L}} + \sqrt{A_1} \right)^2 = \frac{\sigma}{4L} (k+1)^2.
\]

When \( \lambda > 0 \), we have
\[
\lambda A_k A_{k+1} \leq M \leq \frac{4L}{\sigma} A_{k+1} \left( \sqrt{A_{k+1}^2 - A_k^2} \right)^2
\]
where the last step is by (19). So
\[
\sqrt{A_{k+1}} \geq \left( 1 + \sqrt{\frac{\lambda \sigma}{4L}} \right) \sqrt{A_k},
\]
which directly implies the second term in max.

Combining Lemma 3, 4 and 5, we derive

**Theorem 6.** For all \( k \geq 1 \) and \( x \in \text{dom } \Psi \),
\[
J(x_k) - J(x) \leq \Delta(x, x_0) \min \left\{ \frac{4L}{\sigma(k+1)^2}, \frac{L - \sigma \lambda_1}{\sigma} \left( 1 + \sqrt{\frac{\sigma \lambda}{4L}} \right)^{-2k+2} \right\}.
\]

Therefore, as long as one of \( \lambda_1 \) and \( \lambda_2 \) is strictly positive such that \( \lambda = \lambda_1 + \lambda_2 > 0 \), \( J(x_k) \) converges linearly. When \( \lambda_1 = 0 \) and \( \lambda_2 > 0 \), \( \psi_k \) contains only one Bregman divergence making it easier to optimize.

**Remark 1.** If (18) is replaced by
\[
\psi_k(z_{k+1}) \geq \psi_k(z_k) + (\lambda A_k + 1) \Delta(z_{k+1}, z_k)
\]
\[
\geq A_k J(x_k) + (\lambda A_k + 1) \frac{\sigma}{2} \| z_{k+1} - z_k \|^2,
\]
then it is not hard to see that the proof of Lemma 4 still goes through. So \( \Psi \) does not need to be \( \lambda_2 \)-sc wrt \( d \), and it suffices to be \( \lambda_2 \sigma \) strongly convex wrt \( \| \cdot \| \). In practice, checking and satisfying the latter condition can be much easier. Similar remark can be made later for AGM-EF-1, and for the ease of exposition we will still assume \( \Psi \) is \( \lambda_2 \)-sc wrt \( d \).

3.1. Notes on the Computations

The whole algorithm relies on solving \( z_k \) efficiently, and it can be dealt with in two ways. First, by (16), minimizing \( \psi_k(x) \) only requires solving the following form of problem:
\[
\min_x A_k \Psi(x) + \Delta(x, u_0) + \lambda_1 \sum_{i=0}^n a_i \Delta(x, u_i)
\]
\[
+ \left( \sum_{i=0}^n a_i \nabla f(u_i), x \right).
\]

This is feasible by Assumption 2, and in practice the gradients of \( f \) and \( d \) can be aggregated on the fly.

The second method requires making one more assumption, in addition to the usual assumption \( \text{dom } \Psi \subseteq \text{dom } d \).

**Assumption 7.** \( \text{dom } d \subseteq \text{dom } \Psi \).

This assumption is often met when \( d \) is the entropy and \( \text{dom } \Psi \) is the simplex. It ensures that \( z_k := \min_{x \in \text{dom } \Psi} \psi_k(x) \) is also a solution of the unconstrained optimization \( \min_{x \in \text{dom } d} \psi_k(x) \). Then when \( \Psi \) is affine on its domain, we can apply Property 6 and the subsequent discussion on inductively updating \( \psi_k(x) \). This scheme is particularly useful in Algorithm 1 because the minimizer \( z_k \) is already available.

Even if Assumption 7 does not hold and \( z_k \) is not an unconstrained minimizer of \( \psi_k(x) \), one can still spend extra computations to find the unconstrained minimizer and inductively update \( \psi_k(x) \). This idea will be useful if the gradient aggregation in the first method is not viable.

3.2. Adaptively tuning the Lipschitz constant

The Algorithm 1 requires the explicit value of \( L \). This is usually not available, or the global maximum cur-
Algorithm 2 AGM-EF-∞ with adaptive $L$.

Require: Down scaling factor $\gamma_d$ and up scaling factor $\gamma_u$ ($\gamma_d, \gamma_u > 1$). An optimistic estimate $L \leq L$. 
1: Arbitrarily initialize $x_0 \in \text{dom } \Psi$. Set $z_0 \leftarrow x_0$. 
2: Set $A_0 \leftarrow L$. 
3: $\psi_0(x) \leftarrow \Delta(x, x_0)$. 
4: $L_0 \leftarrow L / \gamma_d$. 
5: for $k = 0, 1, \ldots$ do 
6: 
7: repeat 
8: $L_{k+1} \leftarrow L_k / \gamma_u$.
9: Assign to $a_{k+1}$ the positive root (in $a$) of $(a+A_k)(\lambda_1 a+\lambda A_k+1)+a \lambda_2 A_k = L_{k+1} \sigma^{-1} a^2$.
10: Do step 6 to 10 of Algorithm 1.
11: until $A_{k+1}J(x_{k+1}) \leq \psi_{k+1}(z_{k+1})$.
12: end for

vature is much larger than the local directional curvature. As a result, the steps size $1/L$ becomes too conservative. From the proof of Lemma 4, it is clear that $L$ is used only to ensure (15). So we can probe smaller values of $L$. The modified algorithm is given in Algorithm 2.

The inner “repeat” loop must terminate in a finite number of steps because $L_k$ grows exponentially and once $L_k \geq L$ the “until” condition must be satisfied. And the number of steps in this inner loop is logarithmic in $L$, with the final $L_k < \gamma_u L$. Moreover, this $L_k$ is decayed by a factor of $\gamma_d$ before being used to initialize $L_{k+1}$. This is in sharp contrast to AGM-PR where the estimates of $L$ must grow monotonically through iterations. Let us formally characterize how adaptively tuning $L$ leads to faster convergence rates through faster growth rate of $A_k$.

Lemma 8. For all $k \geq 1$,

$$A_k \geq \max \left\{ \frac{\sigma}{L_1 - \sigma \lambda_1} \prod_{i=2}^{k} \left( 1 + \sqrt{\frac{\sigma \lambda_i}{L_i}} \right)^2, \right. $$

$$\left. \frac{\sigma}{4} \left( \sqrt{\frac{\sigma}{L_1}} + \sum_{i=2}^{k} \sqrt{\frac{\sigma}{L_i}} \right)^2 \right\}. $$

Proof. Simply replace the $L$ in (19) by $L_{i+1}$.  

In practice, we observed that the $L_k$ is often only 10 per cent of the real $L$ and therefore by Lemma 8 the convergence rate is 10 times faster than using $L$. Moreover, the $L_k$ in successive iterations are quite close so the inner loop terminates in only 2-3 steps.

This adaptive scheme relies on the fact that the key relationship (15) is independent of $L$ and involves function values only at two points (rather than globally). In contrast, the algorithm and analysis in [26] keep a global relationship which explicitly involves $L$, making it hard to accommodate adaptive $L$.

We also tried to adaptively tune $\lambda$, but not successful. This is turns out to be very hard because the proof uses $\lambda$ as a a global property (recall the fact that $\psi_k$ must be $(\lambda A_k+1)$ wrt $d$), while $L$ is used only at $u_{k+1}$ and $x_{k+1}$ in Step (g) of the proof of Lemma 4.

### 3.3. Bounding the Duality Gap

Algorithm 1 does not have a termination criterion, and a natural criterion will be based on the duality gap. Furthermore, in some applications like (1) the primal problem is nonsmooth and AGM-EF-∞ is applied only to its dual problem which is l.c.g. So it is necessary to convert the dual iterates at each step into the primal, and characterize the convergence rate in the primal. In this subsection, we extend the technique in [2, Section 2] to the case of composite objective. Except the strong convexity, our whole setting and procedure bear much resemblance to [9], [2, Theorem 2.2], [6, Theorem 3] and [17, Section 6]. We are unaware of any existing result which shows linear convergence of the duality gap as we will describe below.

Consider a minimax problem

$$\min_{x} \max_{\alpha \in Q_2} \phi(x, \alpha) + \Psi(x).$$

Here $\Psi : \mathbb{R}^p \rightarrow \mathbb{R}$ is proper, lower semicontinuous and $\lambda_2$-sc wrt $d (\lambda_2 \geq 0)$. Let $\Psi$ satisfy Assumption 2. $Q_2$ is a compact convex set in the Euclidean space. $\phi : \mathbb{R}^p \times Q_2 \rightarrow \mathbb{R}$ is continuous on dom $\Psi \times Q_2$. For all fixed $\alpha \in Q_2$, $\phi(\cdot, \alpha)$ is $\lambda_1$-sc wrt $d (\lambda_1 \geq 0)$ and is differentiable on a open set containing dom $\Psi$. For all fixed $x \in \text{dom } \Psi$, $\phi(x, \cdot)$ is strictly concave. Therefore, the argmax$_{\alpha \in Q_2} \phi(x, \alpha)$ is unique and we denote it as $\alpha(x)$.

Let us define

$$f(x) := \max_{\alpha \in Q_2} \phi(x, \alpha).$$

Then by Denskin’s theorem [27, Theorem B.25], $f$ must be convex and differentiable on dom $\Psi$. We further assume that $f$ is $L$-l.c.g on dom $\Psi$. A key strong convexity property of $f$ is:

Lemma 9. Given all the above assumptions on $\phi$, $f(x)$ must be $\lambda_1$-sc. However, the converse is not necessarily true, i.e. $f(x)$ being $\lambda_1$-sc does not entail that $\phi(\cdot, \alpha)$ is $\lambda_1$-sc for all fixed $\alpha \in Q_2$.  

8
For any \( x_1, x_2 \in \text{dom } \Psi \), we have
\[
f(x_2) = \max_{\alpha \in Q_2} \phi(x_2, \alpha) \geq \phi(x_2, \alpha(x_1))
\]
\[
\geq \phi(x_1, \alpha(x_1)) + \langle \nabla_x \phi(x_1, \alpha(x_1)), x_2 - x_1 \rangle + \lambda_1 \Delta(x_2, x_1)
\]
\[
= f(x_1) + \langle \nabla f(x_1), x_2 - x_1 \rangle + \lambda_1 \Delta(x_2, x_1),
\]
where the last step is by Denskin’s theorem.

We also define a dual objective
\[
J(\alpha) := \Psi(x) + \max_{\alpha \in Q_2} \phi(x, \alpha)
\]
\[
D(\alpha) := \min_{x} \{ \phi(x, \alpha) + \Psi(x) \} \quad \text{for } \alpha \in Q_2
\]
where the argmin in (21) may be not unique and \( D(\alpha) \) may be nonsmooth. Our assumptions above ensure that for any \( \alpha \in Q_2 \) and any \( x \), the following is true:
\[
D(\alpha) \leq J(x), \quad \text{and} \quad \max_{\alpha \in Q_2} D(\alpha) = \min_{x} J(x).
\]

When applied to minimize \( J(x) \), AGM-EF-\( \infty \) (with or without adaptive \( L \)) produces a sequence of \( \{x_k, u_k, z_k\} \). It is our goal to design a sequence of dual variables \( \{\alpha_k\} \) based on \( \{x_k, u_k, z_k\} \) such that the duality gap
\[
\delta_k := J(x_k) - D(\alpha_k)
\]
goes to 0 fast. Since
\[
\delta_k \geq J(x_k) - \max_{\alpha \in Q_2} D(\alpha) = J(x_k) - \min_{x} J(x),
\]
so once \( \delta_k \) falls below a prescribed tolerance \( \epsilon \), \( x_k \) is guaranteed to be an \( \epsilon \) accurate solution of \( J \). Indeed we will show that the following construction of \( \alpha_k \) meets our need:
\[
\alpha_k = \frac{1}{A_k} \sum_{i=1}^{k} a_i \alpha(u_i), \quad (22)
\]

where \( a_i \) and \( A_k \) are also from AGM-EF-\( \infty \). (22) can be equivalently reformulated into a recursion which allows efficient update of \( \alpha_k \):
\[
\alpha_1 = \alpha(u_1), \quad \text{and} \quad \alpha_{k+1} = \frac{A_k}{A_{k+1}} \alpha_k + \frac{a_{k+1}}{A_{k+1}} \alpha(u_{k+1}).
\]

**Theorem 10.** Suppose a sequence \( \{x_k, u_k, z_k\} \) is produced when AGM-EF-\( \infty \) is applied to minimize \( J(x) \) by treating \( f \) as \( \lambda_1 \)-sc. Then the \( \{\alpha_k\} \) defined by (22) satisfies \( \alpha_k \in Q_2 \) and
\[
\delta_k = J(x_k) - D(\alpha_k) \leq \frac{1}{A_k} \max_{x \in \text{dom } \Psi} \Delta(x, u_0).
\]

**Proof.** Since \( u_i \in \text{dom } \Psi \), so \( \alpha(u_i) \in Q_2 \). And \( \alpha_k \) is a convex combination of \( \alpha(u_i) \) (\( i \leq k \)), so \( \alpha_k \in Q_2 \). Using the fact that \( \phi(x, \alpha) \) is \( \lambda_1 \)-sc in \( \alpha \) for all fixed \( x \), we have
\[
\ell_f(x; u_i, \lambda_1) = f(u_i) + \langle \nabla f(u_i), x - u_i \rangle + \lambda_1 \Delta(x, u_i)
\]
\[
= \phi(u_i, \alpha(u_i)) + \langle \nabla_x \phi(u_i, \alpha(u_i)), x - u_i \rangle + \lambda_1 \Delta(x, u_i)
\]
\[
\leq \phi(x, \alpha(u_i)).
\]
Now by using relationship (15) and (16), we have
\[
A_k J(x_k) \leq \min_{x} \left\{ \Delta(x, u_0) + A_k \Psi(x) + \sum_{i=1}^{k} a_i \ell_f(x; u_i, \lambda_1) \right\}
\]
\[
\leq \min_{x} \Delta(x, u_0) + A_k \Psi(x) + \sum_{i=1}^{k} a_i \phi(x, \alpha(u_i))
\]
\[
\leq \min_{x} \Delta(x, u_0) + A_k \Psi(x) + A_k \phi \left( x, \frac{1}{A_k} \sum_{i=1}^{k} a_i \alpha(u_i) \right)
\]
\[
\leq \max_{x \in \text{dom } \Psi} \Delta(x, u_0) + A_k \min_{x} \{ \Psi(x) + \phi(x, \alpha_k) \}
\]
\[
= \max_{x \in \text{dom } \Psi} \Delta(x, u_0) + A_k D(\alpha_k).
\]
So \( \delta_k \) converges linearly as long as \( \lambda_2 > 0 \). If \( \text{dom } \Psi \) is unbounded and \( \max_{x \in \text{dom } \Psi} \Delta(x, u_0) = \infty \), then the bound in (23) becomes vacuous.

We emphasize that in Theorem 10, AGM-EF-\( \infty \) is invoked by treating \( f \) as \( \lambda_1 \)-sc, although the real strong convexity constant \( \lambda_1' \) of \( f \) may be greater than \( \lambda_1 \). In this case, the duality gap will decay at a slower rate than that for the gap of \( J \) (by using \( \lambda_1' \) in AGM-EF-\( \infty \)). However the strong convexity of \( \Psi \) is still fully utilized in the duality gap, and in many machine learning problems the strong convexity does come from \( \Psi \) rather than \( f \) (i.e. \( \lambda_1 = \lambda_1' = 0 \)).

### 4. 1-memory AGM-EF

Note that AGM-EF-\( \infty \) keeps a nonparametric form (16) of the model \( \psi_k(x) \) whose complexity grows with iteration. In 1-memory AGM-EF, the model is compressed to a simple parametric form in each iteration. Auslender and Teboulle [28] gave a Bregman version for unconstrained optimization. [18] provided an algorithm for constrained problems with Euclidean distance as the prox-function. However, only [26] and [9] accommodate both Bregman divergence and constraints. But their algorithms do not extend to strongly convex objectives and restrict the estimate of \( L \) to be nondecreasing through iterations. Therefore, we propose in this section a 1-memory AGM-EF.
Algorithm 3 1-memory AGM-EF (AGM-EF-1).

1: Arbitrarily pick \( u_0 \in \text{dom } \Psi \).
2: Initialize \( c_0 \leftarrow \frac{L}{\sigma} + \lambda_2 \).
3: \( q_0(x) \leftarrow \frac{L}{\sigma} \Delta(x, u_0) + \Psi(x) + \ell_f(x; u_0, 0) \).
4: \( x_0 = z_0 \leftarrow \text{argmin}_x q_0(x) \).
5: for \( k = 0, 1, \ldots \) do
6: Assign to \( a_{k+1} \) the positive root (in \( a \)) of \( \sigma(1-a)(c_k + \lambda_2 a) + \sigma \lambda_1 a = L a^2 \).
7: \[ c_{k+1} \leftarrow \left(1 - a_{k+1}\right) c_k + \left(1 + \lambda_2 a_{k+1}\right), \]
\[ \tau_k \leftarrow 1 - a_{k+1}, \tau_2 \leftarrow \lambda_1 a_{k+1}, \]
\[ \tau_3 \leftarrow \lambda_2 \tau_{k+1} \left(1 - a_{k+1}\right), \tau \leftarrow \tau_1 + \tau_2 + \tau_3. \]
8: \[ u_{k+1} \leftarrow \left(\tau_2 - \tau_{k+1}\right) u_k + \tau_{k+1} u_{k+1}. \]
9: Free \( \tau \) and \( \tau_2^{-1}, \tau_3^{-1}, c_{k+1} \).
10: \[ \psi_{k+1}(x) \leftarrow \text{argmin}_x \psi_{k+1}(x). \]
11: \[ x_{k+1} \leftarrow \left(1 - a_{k+1}\right) x_k + a_{k+1} z_{k+1}. \]
12: \( q_{k+1}(x) \leftarrow c_{k+1} \Delta(x, z_{k+1}) + \psi_{k+1}(z_{k+1}). \)
13: end for

which uses Bregman prox-function, and allows constraints and non-monotonic adaptive tuning of \( L \).

 Arbitrarily pick \( u_0 \in \text{dom } \Psi \) and initialize by

\[
q_0(x) := \frac{L}{\sigma} \Delta(x, u_0) + f(x_0) + \langle \nabla f(u_0), x - u_0 \rangle + \Psi(x)
\]

\[ x_0 = z_0 \leftarrow \text{argmin}_x q_0(x) \]
\[ c_0 = \frac{L}{\sigma} + \lambda_2. \]

Then for all \( k \geq 0 \), define:

\[
\psi_{k+1}(x) = (1 - a_{k+1}) q_k(x) + a_{k+1} \left[ \ell_f(x; u_{k+1}, \lambda_1) + \Psi(x) \right]
\]

\[ z_{k+1} \leftarrow \text{argmin}_x \psi_{k+1}(x) \]
\[ c_{k+1} = (1 - a_{k+1}) c_k + \lambda a_{k+1} \]
\[ q_{k+1}(x) = c_{k+1} \Delta(x, z_{k+1}) + \psi_{k+1}(z_{k+1}). \]

By construction for all \( k \geq 0 \), \( q_k \) is \( c_k \)-sc and \( \psi_{k+1} \) is strongly convex with constant \( (1 - a_{k+1}) c_k + \lambda a_{k+1}, \)
\( i.e. \) \( c_{k+1} \)-sc. Clearly, for all \( k \geq 1 \)

\[
\min_x \psi_k(x) = \psi_k(z_k) = q_k(z_k) = \min_x q_k(x). \quad \text{(25)}
\]

But except at \( x = z_k \), \( q_k(x) \neq \psi_k(x) \) in general. The only case where \( q_k(x) \equiv \psi_k(x) \) is when \( \Psi(x) \) is an affine function on \( d \) and \( d \subseteq \text{dom } \Psi \). Then an inductive application of Property 6 reveals \( q_k(x) \equiv \psi_k(x) \). Lemma 5.2 of [23] is exactly this case with \( \Psi(x) \equiv 0 \). However, when \( d \not\subseteq \text{dom } \Psi \) then \( z_{k+1} \)

\( q_{k+1}(z_{k+1}) = \psi_{k+1}(z_{k+1}) \]
\[ = (1 - a_{k+1}) q_k(z_{k+1}) + a_{k+1} \left[ \ell_f(z_{k+1}; u_{k+1}, \lambda_1) + \Psi(z_{k+1}) \right] \]
\[ \geq (1 - a_{k+1}) q_k(z_{k+1}) + c_k \Delta(z_{k+1}, z_k). \quad \text{(26)} \]

The proof of rate of convergence for Algorithm 3 relies on the following two relations: for all \( k \geq 0 \) and \( x \in \text{dom } \Psi \),

\[
q_{k+1}(x) - J(x) \leq (1 - a_{k+1}) (q_k(x) - J(x)) \quad \text{(26)}
\]
\[ J(x_k) \leq q_k(z_k). \quad \text{(27)} \]

From these three inequalities, we get for all \( x \in \text{dom } \Psi \),

\[ J(x_k) \leq q_k(z_k) \leq q_k(x) \]
\[ \leq J(x) + (q_0(x) - J(x)) \cdot \prod_{i=1}^{k} (1 - a_i). \quad \text{(28)} \]

So the gap \( J(x_k) - J(x) \) decays at the same rate as \( \prod_{i=1}^{k} (1 - a_i) \).\(^6\) Compared with the \( \infty \)-memory AGM-EF, the additional inequality (26) is now needed because the models \( q_k \) here are approximations of the \( \psi_k \) in (16). Next, we prove the three relations one by one.

Lemma 11 (Eq (26)). For all \( k \geq 0 \) and \( x \), we have

\[ q_{k+1}(x) - J(x) \leq (1 - a_{k+1}) (q_k(x) - J(x)). \]

Proof. Since \( z_{k+1} \) minimizes \( \psi_{k+1}(x) \) and \( \psi_{k+1}(x) \) is \( c_{k+1} \)-sc, so by Property 5 we have

\[ \psi_{k+1}(x) \geq \psi_{k+1}(z_{k+1}) + c_{k+1} \Delta(x, z_{k+1}). \quad \text{(29)} \]

So for all \( x \in Q \),

\[ (1 - a_{k+1}) q_k(x) + a_{k+1} J(x) \geq (1 - a_{k+1}) q_k(x) + a_{k+1} (\ell_f(x; u_{k+1}, \lambda_1) + \Psi(x)) \]
\[ = \psi_{k+1}(x) \]
\[ \geq \psi_{k+1}(z_{k+1}) + c_{k+1} \Delta(x, z_{k+1}) \quad \text{(by (29))} \]
\[ = q_{k+1}(x). \quad \text{(31)} \]

Lemma 12 (Eq (27)). For all \( k \geq 0 \), \( J(x_k) \leq q_k(z_k) \).

Proof. We prove by induction. First, when \( k = 0 \) \( q_0(z_0) = J(x_0) \). Now suppose (27) holds for certain \( k \geq 0 \). Then

\[
q_{k+1}(z_{k+1}) = \psi_{k+1}(z_{k+1}) \]
\[ = (1 - a_{k+1}) q_k(z_{k+1}) + a_{k+1} \left[ \ell_f(z_{k+1}; u_{k+1}, \lambda_1) + \Psi(z_{k+1}) \right] \]
\[ \geq (1 - a_{k+1}) \left[ q_k(z_k) + c_k \Delta(z_{k+1}, z_k) \right]. \quad \text{(31)} \]
\[ + a_{k+1} I_f (z_{k+1}; u_{k+1}, \lambda_1) + \Psi(z_{k+1}) \]
\[ \geq (1 - a_{k+1}) [f(x_k) + \Psi(x_k) + \Delta(z_{k+1}, z_k)] 
+ a_{k+1} I_f (x_{k+1}; u_{k+1}, \lambda_1) + (1 - a_{k+1}) \Psi(z_{k+1}) \]
\[ (c) \geq (1 - a_{k+1}) [f(u_{k+1}) + \langle \nabla f(u_{k+1}), x_k - u_{k+1} \rangle 
+ \frac{c_k \sigma}{2} \| z_{k+1} - z_k \|^2 + a_{k+1} I_f (u_{k+1}) 
+ \langle \nabla f(u_{k+1}), z_{k+1} - u_{k+1} \rangle + \frac{\lambda_1 \sigma}{2} \| z_{k+1} - u_{k+1} \|^2 
+ (1 - a_{k+1}) \Psi(x_k) + a_{k+1} \Psi(z_{k+1}) \]
\[ (d) \geq \Psi(x_{k+1}) + f(u_{k+1}) 
+ \langle \nabla f(u_{k+1}), (1 - a_{k+1}) x_k + a_{k+1} z_{k+1} - u_{k+1} \rangle 
+ \frac{\sigma}{2} c_k (1 - a_{k+1}) \| z_{k+1} - z_k \|^2 
+ \frac{\sigma}{2} \lambda_1 a_{k+1} \| z_{k+1} - u_{k+1} \|^2 
+ \frac{\sigma}{2} \lambda_2 a_{k+1} (1 - a_{k+1}) \| z_{k+1} - x_k \|^2 \]
\[ (e) \geq \Psi(x_{k+1}) + f(u_{k+1}) 
+ \langle \nabla f(u_{k+1}), (1 - a_{k+1}) x_k + a_{k+1} z_{k+1} - u_{k+1} \rangle 
+ \frac{\sigma}{2} (\tau_1 + \tau_2 + \tau_3) \| z_{k+1} - \tau_1 z_k + \tau_2 u_{k+1} + \tau_3 x_k \|_2^2 \]
\[ (f) \geq \Psi(x_{k+1}) + f(u_{k+1}) 
+ \langle \nabla f(u_{k+1}), x_k - u_{k+1} \rangle + \frac{L}{2} \| x_{k+1} - u_{k+1} \|^2 \]
\[ (g) \geq \Psi(x_{k+1}) + f(x_{k+1}) = J(x_{k+1}), \]

where (a) is because \( z_k \) minimizes \( q_k \) and \( q_k \) is \( c_k \)-sc; (b) is by the induction assumption. (c) is by the convexity of \( f \) and \( \sigma \)-sc of \( d \). (d) is by the \( \lambda_2 \)-sc of \( \Psi \) and Property 1. (e) is by the convexity of norm. (f) is by the definition of \( x_{k+1} \) and \( u_{k+1} \), and the choice of \( a_{k+1} \). (g) is by the \( L \)-l.c.g of \( f \).

Finally we bound \( q_0(x) - J(x) \) by
\[ q_0(x) - J(x) \]
\[ = \frac{L}{\sigma} \Delta(x, u_0) + \langle \nabla f(u_0), x - u_0 \rangle + f(u_0) - f(x) \]
\[ \leq \left( \frac{L}{\sigma} - \lambda_1 \right) \Delta(x, u_0). \] (by \( \lambda_1 \)-sc of \( f \)) \hfill (32)

By (28) and the definition \( c_0 = L' \), we get

**Theorem 14.** For all \( k \geq 1 \) and \( x \in \text{dom} \Psi \),

\[ J(x_k) - J(x) \]
\[ \leq (q_0(x) - J(x)) \min \left\{ \left( 1 - \sqrt{\frac{\lambda}{L'}} \right)^k, \frac{4}{(2 + k)^2} \right\} \]
\[ \leq \left( \frac{L}{\sigma} - \lambda_1 \right) \Delta(x, u_0) \min \left\{ \left( 1 - \sqrt{\frac{\lambda}{L'}} \right)^k, \frac{4}{(2 + k)^2} \right\} . \]

This rate is completely independent of \( \Psi \) (except \( \lambda_2 \)). Although not needed by the proof, we can further show that \( q_k(x) \geq J(x) \) for all \( k \geq 0 \) and \( x \in \text{dom} \Psi \).

**Lemma 15.** \( q_k(x) \geq J(x) \) for all \( k \geq 0 \) and \( x \in \text{dom} \Psi \).

**Proof.** When \( k = 0 \),
\[ q_0(x) = \frac{L}{\sigma} \Delta(x, u_0) + f(u_0) + \langle \nabla f(u_0), x - u_0 \rangle + \Psi(x) \]
\[ \geq \frac{L}{2} \| x - u_0 \|^2 + f(u_0) + \langle \nabla f(u_0), x - u_0 \rangle + \Psi(x) \]
\[ \geq f(x) + \Psi(x) = J(x). \]

Suppose \( k \geq 1 \). By (25), \( q_k(x) \geq q_k(z_k) \). By Lemma 12, \( q_k(z_k) \geq J(x_k) \). So
\[ q_k(x) \geq q_k(z_k) \geq J(x_k) \geq J(x). \] \hfill ■

### 4.1. Adaptive \( L \)

It is straightforward to incorporate backtracking of \( L \) into the algorithm. We present this variant in Algorithm 4. Suppose at each iteration the inner loop terminates with \( L_k \) and define \( L'_k = L_k / \sigma + \lambda_2 \). Noting \( c_0 = L'_0 \) and slightly changing the proof, Lemma 13 can be extended as follows:

**Lemma 16.** For all \( k \geq 1 \), we have
\[ \prod_{i=1}^{k} (1 - a_i) \leq \min \left\{ \prod_{i=1}^{k} \left( 1 - \sqrt{\frac{\lambda}{L_i}} \right), \frac{4}{L'_0 \left( \frac{2}{L'_0} + \sum_{i=1}^{k} \frac{1}{L'_i} \right)^2} \right\} . \]

Obviously, when \( L'_i = L' \) we recover Lemma 13.
Algorithm 4 AGM-EF-1 with adaptive $L$

Require: Down scaling factor $\gamma_d$ and up scaling factor $\gamma_u$ ($\gamma_d, \gamma_u > 1$). An optimistic estimate $\hat{L} \leq L$.

1: Arbitrarily pick $u_0 \in \text{dom } \Psi$. $L_0 \leftarrow \hat{L}/\gamma_u$.
2: repeat
3: $L_0 \leftarrow L_0 \cdot \gamma_u$.
4: Initialize $c_0 \leftarrow -\frac{L_0}{\sigma} + \lambda_2$.
5: $q_0(x) \leftarrow -\frac{L_0}{\sigma} \Delta(x, u_0) + b_0(\Psi(x) + \ell_f(x; u_0, 0))$.
6: $x_0 = z_0 \leftarrow \text{argmin}_{x} q_0(x)$.
7: until $J(x_0) \leq \min_{x} q_0(x)$
8: for $k = 0, 1, \ldots$ do
9: $L_{k+1} \leftarrow L_k/\gamma_d \cdot \gamma_u$.
10: repeat
11: Assign to $a_k+1$ the positive root (in $a$) of $\sigma(1-a)(c_k + 2\lambda_2a) + \sigma \lambda_1a = L_{k+1}a^2$.
12: Do step 7 to 12 of Algorithm 3.
13: end for
14: until $J(x_{k+1}) \leq q_{k+1}(\bar{z}_{k+1})$
15: end for

Furthermore, (32) needs to be changed into

$$q_0(x) - J(x) \leq \left(\frac{L_0}{\sigma} - \lambda_1\right) \Delta(x, u_0).$$

So we conclude for all $k \geq 1$ and $x \in \text{dom } \Psi$,

$$J(x_k) - J(x) \leq \left(L_0 - \lambda\right) \Delta(x, u_0)$$

$$\cdot \min \left\{ \prod_{i=1}^{k} \left(1 - \sqrt{\frac{1}{L_i}}\right), \frac{4}{L_0} \left(\frac{2}{\sqrt{L_0}} + \sum_{i=1}^{k} \frac{1}{\sqrt{L_i}}\right)^{-2} \right\}.$$ 

This bound does not involve the true $L$, and does not depend on $\Psi$ or the function value of $f$ (which could be used to hide $L$).

4.2. Bounding the duality gap

It is also not hard to extend AGM-EF-1 to the same primal-dual settings as in Section 3.3.

Using (30) and (31), we derive for all $x \in \text{dom } \Psi$:

$$q_{k+1}(x) \leq (1 - a_{k+1}) q_k(x) + a_{k+1} [\ell_f(x; u_{k+1}, \lambda_1) + \Psi(x)].$$

(33)

This inequality allows us to express $q_k$ in terms of the linearizations of $f$ at $u_i$. For notational convenience, define $a_0 = 1$ and

$$b_k(i) := a_i \prod_{j=i+1}^{k} (1 - a_j) \quad \text{for all } 0 \leq i \leq k,$$

then it is easy to see that $\sum_{i=0}^{k} b_k(i) = 1$ for all $k \geq 1$.

Lemma 17. For all $x \in \text{dom } \Psi$ and $k \geq 1$,

$$q_k(x) \leq b_k(0)q_0(x) + \sum_{i=1}^{k} b_k(i) \ell_f(x; u_i, \lambda_1) + \Psi(x)$$

$$\leq \frac{L}{\sigma} b_k(0) \Delta(x, u_0) + \Psi(x) + \sum_{i=0}^{k} b_k(i) \ell_f(x; u_i, \lambda_1).$$

(34)

Proof. The inequality is obvious by inductively applying (33). The equality is by the definition of $q_0(x)$ and the fact that $\sum_{i=0}^{k} b_k(i) = 1$.

Go back to the settings of Section 3.3. We minimize $J(x)$ by AGM-EF-1 and find some dual iterates $\alpha_k$ such that the duality gap $J(x_k) - D(\alpha_k)$ goes to 0 fast. Similar to (22), we construct

$$\alpha_k = \sum_{i=0}^{k} b_k(i) \alpha(u_i).$$

(35)

Comparing with (22), we can see that both formulae are convex combinations of all the past $\alpha(u_i)$ and higher weights are given to the later $\alpha(u_i)$. Computationally, $\alpha_k$ can be efficiently updated by recursion $\alpha_0 = \alpha(u_0)$, and $\alpha_{k+1} = (1-a_{k+1}) \alpha_k + a_{k+1} \alpha(u_{k+1})$.

To be self-contained, we state and prove the counterpart of Theorem 10 here.

Theorem 18 (Bounds on the duality gap). Suppose a sequence $\{x_k, u_k, z_k\}$ is produced when AGM-EF-1 is applied to minimize $J(x)$ by treating $f$ as $\lambda_1$-sc. Then the $\{\alpha_k\}$ defined by (35) satisfies $\alpha_k \in Q_2$ and

$$J(x_k) - D(\alpha_k) \leq \frac{L}{\sigma} b_k(0) \max_{x \in \text{dom } \Psi} \Delta(x, u_0).$$

(36)

Proof. Since $\alpha(u_i) \in Q_2$ and $\alpha_k$ is a convex combination of them, so $\alpha_k \in Q_2$. Clearly, (24) still holds. Denote the right-hand side of (36) as $M$. Now by using relationship (34) and Lemma 12, we have

$$J(x_k) \leq \min_x q_k(x)$$

$$\leq \min_x \left\{ \frac{L}{\sigma} b_k(0) \Delta(x, u_0) + \Psi(x) + \sum_{i=0}^{k} b_k(i) \ell_f(x; u_i, \lambda_1) \right\}$$

$$\leq M + \min_x \left\{ \Psi(x) + \sum_{i=0}^{k} b_k(i) \phi(x, \alpha(u_i)) \right\}$$

$$\leq M + \min_x \left\{ \Psi(x) + \phi \left( x, \sum_{i=0}^{k} b_k(i) \alpha(u_i) \right) \right\}$$

$$\leq M + D(\alpha_k).$$

$\blacksquare$
5. Application to Regularized Risk Minimization

Regularized risk minimization (RRM) is extensively used in machine learning. In this section, we describe and compare in theory many different ways of training these models by APM. The objective of RRM with linear models can be written as

$$\min_{w \in Q_1} J(w) = \Omega(w) + g^*(A w),$$  \hspace{1cm} (37)

where $Q_1$ is a closed convex set. Here, $\Omega(w)$ corresponds to the regularizer and is assumed to be $\lambda$-sc wrt some prox-function $d_1$ on $Q_1$. $d_1$ is in turn assumed to be $\sigma_1$-sc wrt a norm $\|\cdot\|$ on $Q_1$. $\text{aw}$ stands for the output of a linear model, and $g^*$ (the Fenchel dual of function $g$) encodes the empirical risk measuring the discrepancy between the correct labels and the output of the linear model ($Aw$). Let the domain of $g$ be $Q_2$, which is also assumed to be closed and convex.

Using the definition of Fenchel dual, the primal objective (37) can be rewritten as a minimax problem:

$$\min_{w \in Q_1} \max_{\alpha \in Q_2} L(w, \alpha) := \Omega(w) + \langle Aw, \alpha \rangle - g(\alpha),$$  \hspace{1cm} (38)

which further leads to the adjoint problem

$$\max_{\alpha \in Q_2} \left\{ -g(\alpha) + \min_{w \in Q_2} \{ \langle Aw, \alpha \rangle + \Omega(w) \} \right\} \equiv \max_{\alpha \in Q_2} D(\alpha) := -g(\alpha) - \Omega^*(-A^\top \alpha).$$  \hspace{1cm} (39)

It is well known [e.g. 29, Theorem 3.3.5] that under some mild constraint qualifications, the primal form $J(w)$ and the adjoint form $D(\alpha)$ satisfy

$$J(w) \geq D(\alpha) \quad \text{and} \quad \inf_{w \in Q_1} J(w) = \sup_{\alpha \in Q_2} D(\alpha).$$

Example 1: binary SVMs with bias. The primal form of the binary linear SVM with bias is:

$$J(w) = \frac{\lambda}{2} \left\| w \right\|_2^2 + \min_{b \in \mathbb{R}} \frac{1}{n} \sum_{i=1}^n \left[ 1 - y_i (\langle x_i, w \rangle + b) \right]_+.$$  \hspace{1cm} (43)

This can be posed in our framework by setting $Q_1 := \mathbb{R}^p$, $A := -X^\top$, $\Omega(w) = \frac{\lambda}{2} \left\| w \right\|_2^2$, $g^*(u) = \min_{b \in \mathbb{R}} \frac{1}{n} \sum_{i=1}^n \left[ 1 + u_i - y_i b \right]_+$. This $g^*$ corresponds to

$$g(\alpha) = \begin{cases} -\sum_i \alpha_i & \text{if } \alpha \in Q_2, \\ +\infty & \text{otherwise,} \end{cases}$$  \hspace{1cm} (40)

where $Q_2$, the domain of $g$, is

$$Q_2 = \left\{ \alpha \in [0, n^{-1}]^n : \sum_i y_i \alpha_i = 0 \right\}.$$

Then the adjoint form turns out to be the well known SVM dual objective:

$$D(\alpha) = \sum_i \alpha_i - \frac{1}{2\lambda} \alpha^\top X^\top X \alpha, \ s.t. \ \alpha \in Q_2.$$  \hspace{1cm} (41)

Example 2: $L_1$ regularized SVM. The primal form of the $L_1$ regularized SVM ($L_1$-SVM, [30]) is:

$$J(w) = \lambda \left\| w \right\|_1 + \min_{b \in \mathbb{R}} \frac{1}{n} \sum_{i=1}^n \left[ 1 - y_i (\langle x_i, w \rangle + b) \right]_+. \hspace{1cm} (42)$$

This can be posed in our framework by exactly the same configurations as above, except that now $\Omega(w) = \lambda \left\| w \right\|_1$. One can show that $\Omega^*(v) = 0$ if $\left\| v \right\|_{\infty} \leq \lambda$, and $\infty$ otherwise. The adjoint form is:

$$D(\alpha) = \begin{cases} \sum_i \alpha_i & \text{if } \left\| X^\top \alpha \right\|_\infty \leq \lambda, \ s.t. \ \alpha \in Q_2, \\ -\infty & \text{otherwise.} \end{cases}$$  \hspace{1cm} (42)

Example 3: multivariate scores. Joachims [31] proposed a max-margin model which directly optimizes the $F_1$ score. Assume there are $n_+$ positive examples and $n_-$ negative examples. $F_1$-score is defined by using the contingency table: $\Delta(y', y) := \frac{2y'y}{2y'y + y' - y}$. 

$$\begin{array}{c|c|c|c}
 y' = 1 & y = 1 & y = -1 \\
 \hline
 a & c & b \\
 b & a + c & d \\
 d & n_- - c & n_+ + n_- \end{array}$$

The primal objective proposed by Joachims [31] is

$$J(w) = \frac{\lambda}{2} \left\| w \right\|_2^2$$  \hspace{1cm} (43)

$$+ \max_{y' \in \{-1, 1\}^n} \left[ \Delta(y', y) + \frac{1}{n} \sum_{i=1}^n \langle w, x_i \rangle (y'_i - y_i) \right].$$
This can be recovered by setting \( Q_1 = \mathbb{R}^p, \Omega(w) = \frac{1}{2} \|w\|^2 \), and letting \( A \) be a \( 2^n \times p \) matrix where the \( y' \)-th row is \( \sum_{i=1}^n x_i \phi(y'_i - y_i) \) for each \( y' \in \{-1, +1\}^n \). Then \( g^*(u) = \max_{y'} \left( \Delta(y', y) + \frac{1}{n} w_{y'} \right) \) which is induced by
\[
g(\alpha) = \begin{cases} -n \sum_{y'} \Delta(y', y)\alpha_{y'} & \text{if } \alpha \in Q_2 \\ +\infty & \text{otherwise}. \end{cases} \quad (44)
\]
Here \( Q_2 \), the domain of \( g \), is
\[
Q_2 = \left\{ \alpha \in [0, n^{-1}]^{2^n} : \sum_{y'} \alpha_{y'} = \frac{1}{n} \right\}.
\]
So we get the adjoint form
\[
D(\alpha) = -\frac{1}{2\lambda} \alpha^T A A^T \alpha + n \sum_{y'} \Delta(y', y)\alpha_{y'}, \ \alpha \in Q_2.
\]

**Example 4: Max-margin Markov Networks.**
The conditional random fields (CRFs) [32] and max-margin Markov network (\( M^3 \)Ns) [33] are also instances of RRM. First, they both minimize a regularized risk with a square norm regularizer. Second, they assume that there is a joint feature map \( \phi \) which maps \( (x, y) \) to a feature vector in \( \mathbb{R}^p \). Third, they assume a label loss \( \ell(y, y'; x') \) which quantifies the loss of predicting label \( y \) when the correct label of input \( x \) is \( y' \). Finally, they assume that the space of labels \( \mathcal{Y} \) is endowed with a graphical model structure and that \( \phi(x, y) \) and \( \ell(y, y'; x') \) factorize according to the cliques of this graphical model. The main difference is in the loss function employed. CRFs minimize the \( L_2 \)-regularized logistic loss:
\[
J(w) = \frac{\lambda}{2} \|w\|^2 + \frac{1}{n} \sum_{i=1}^n \log \sum_{y \in \mathcal{Y}} \exp(\ell(y, y'; x^i)) - \langle w, \phi(x^i, y') - \phi(x^i, y) \rangle,
\]
while the \( M^3 \)Ns minimize the \( L_2 \)-regularized hinge loss
\[
J(w) = \frac{\lambda}{2} \|w\|^2 + \frac{1}{n} \sum_{i=1}^n \max_{y \in \mathcal{Y}} \{\ell(y, y'; x^i) - \langle w, \phi(x^i, y') - \phi(x^i, y) \rangle\}.
\]
Clearly, both cases employ \( Q_1 = \mathbb{R}^p \) and \( \Omega(w) = \frac{1}{2} \|w\|^2 \). With shorthand \( \psi^i_y := \phi(x^i, y') - \phi(x^i, y) \) and \( \ell^i_y := \ell(y, y'; x^i) \), they both use an \( (|\mathcal{Y}|) \times p \) matrix \( A \) whose \( (i, y) \)-th row is \( -\psi^i_y \). For \( M^3 \)Ns, \( g^*(u) = \frac{1}{2} \sum_i \max_y \{\ell^i_y + u_{y'}^i\} \) and it can be verified that the corresponding \( g \) is
\[
g(\alpha) = \begin{cases} -\sum_y \sum_{i} \ell^i_y \alpha^i_y & \text{if } \alpha \in Q_2 \\ +\infty & \text{otherwise}, \end{cases} \quad (47)
\]
where \( Q_2 \), the domain of \( g \), is
\[
Q_2 = S^n := \left\{ \alpha \in [0, 1]^{|\mathcal{Y}|} : \sum_y \alpha^i_y = \frac{1}{n}, \ \forall \ i \right\}.
\]
Clearly, \( Q_2 \) is convex and compact. Now the adjoint form can be written as
\[
D(\alpha) = -\frac{1}{2\lambda} \alpha^T A A^T \alpha + \sum_{i=1}^n \sum_y \ell^i_y \alpha^i_y, \ \alpha \in S^n. \quad (48)
\]
For CRFs, \( g^*(u) = \frac{1}{n} \sum y \exp(\ell^i_y + u_{y'}^i) \), and the corresponding \( g \) is
\[
g(\alpha) = \begin{cases} \sum_{i=1}^n \sum_y \alpha^i_y (\log \alpha^i_y - \ell^i_y) + \log n & \text{if } \alpha \in Q_2 \\ +\infty & \text{otherwise}, \end{cases} \quad (49)
\]
The domain of \( g \) is also \( Q_2 = S^n \). Then the adjoint form is
\[
D(\alpha) = -\frac{1}{2\lambda} \alpha^T A A^T \alpha + \sum_{i=1}^n \sum_y \alpha^i_y (\log \alpha^i_y - \ell^i_y) + \log n, \ \alpha \in S^n.
\]

**Example 5: Entropy regularized LPBoost.**
In [13], the entropy regularized LPBoost needs to minimize
\[
J(w) = \lambda \Delta(w, w^0) + \max_{i \in [t]} \langle u_i, w \rangle,
\]
subject to \( w \in Q_1 := \{ w \in [0, \nu]^n : \sum_{i=1}^n w_i = 1 \} \).

Here \( \nu \) is a constant in \([0, 1]\), \( w^0 \in Q_1 \) is the uniform distribution, and \( \Delta \) is the Bregman divergence induced by the entropy (\( i.e. \Delta \) is the relative entropy). \( u_i \in \mathbb{R}^n \) is the so called edge vector. This objective corresponds to \( \Omega(w) = \lambda \Delta(w, w^0) \), \( A = (u_1, \ldots, u_t)^T \), \( g^*(s) = \max_i, s_i \), which is induced by \( g(\alpha) = 0 \) if \( \alpha \in Q_2 := S_1 \), and \( \infty \) otherwise. Since
\[
\Omega^*(s) = -\min_{\beta_i \geq 0} \alpha \left\{ \lambda \log \sum_{i=1}^n w_i^0 \exp \left( \frac{s_i - \beta_i}{\lambda} \right) + \nu \sum_{i=1}^n \beta_i \right\},
\]
so the adjoint form can be written as
\[
D(\alpha) = -\min_{\beta_i \geq 0} \left\{ \lambda \log \sum_{i=1}^n w_i^0 \exp \left( \frac{A_{i}^T \alpha + \beta_i}{\lambda} \right) + \nu \sum_{i=1}^n \beta_i \right\}
\]
subject to \( \alpha \in Q_2 = S_1 \). Here \( A_{i} \) denotes the \( i \)-th column of \( A \). Although this form of \( D(\alpha) \) is obscure, the strong convexity of \( \Omega \) implies that \( D(\alpha) \) is l.c.g. The \( \nu \) is introduced by [13] to cap the density, and this cap is removed if \( \nu = \infty \). In that case, \( \beta_i \) in the definition of \( D(\alpha) \) will all be optimized to 0 and we recover the well known log-sum-exp formula of \( D(\alpha) \).
Example 6: Elastic net Using square loss as an example of the empirical risk, the primal objective of elastic net regularization is

\[ J(w) = \lambda \left( \gamma \|w\|_1 + \frac{1}{2} \|w\|_2^2 \right) + \frac{1}{n} \sum_{i=1}^{n} (y_i - x_i^\top w)^2. \]  

Here the L1 normalizer \( \|w\|_1 \) is introduced to promote the sparsity of the solution. In this case, \( \Omega(w) = \lambda \left( \gamma \|w\|_1 + \frac{1}{2} \|w\|_2^2 \right) \) and it dual is left as an exercise for the reader. An equivalent formulation of (52) is by moving the regularizer into the constraint:

\[
\min_w J(w) = \frac{1}{n} \sum_{i=1}^{n} (y_i - x_i^\top w)^2 \quad \text{s.t.} \quad \gamma \|w\|_1 + \frac{1}{2} \|w\|_2^2 \leq r.
\]

It can be shown that for any \( \lambda > 0 \) there exists an \( r > 0 \) such that \( \text{argmin} J = \text{argmin} J \) and vice versa.

There are also many regularized risk minimization problems which optimize over the space of positive semi-definite matrices, e.g. [2, 14, 34].

Summary From these examples, we can see the following properties of \( \Omega \) and \( g \) which will also be assumed for our general treatment of the objective (37) and (39). Firstly, the function \( \Omega(w) \) which serves as a regularizer is strongly convex. In Example 1, 3, 4, 6, \( \Omega(w) \) is \( \lambda \)-sc wrt the Euclidean norm. In Example 5, \( f(w) \) is \( \lambda \)-sc wrt the L1 norm. As a result, \( \Omega^* \) must be \( \frac{1}{\lambda} \)-l.c.g on \( \mathbb{R}^p \). Secondly, the l.c.g constant of \( \Omega^*(-A^\top \alpha) \) in \( \alpha \) also depends on the matrix norm of \( A \), which in turn depends on the choice of norm on \( Q_1 \) and \( Q_2 \). Thirdly, the \( g^* \) is not necessarily differentiable (e.g., hinge loss), but \( g \) is always l.c.g on \( Q_2 \). Finally, \( Q_2 \) is bounded and its diameter can be well controlled. This is important for translating dual solutions into the primal.

Our goal is to minimize \( J(w) \) over \( Q_1 \), and we do not really care about solving the dual \( D(\alpha) \) over \( Q_2 \). However, since \( D(\alpha) \) has favorable smooth properties, we also often work in the dual as a proxy. To solve \( J(w) \) (and \( D(\alpha) \)), there are three main approaches.

Smoothing \( g^* \) to a fixed level. To handle the nonsmoothness of \( g^* \), we can smooth it by using the technique introduced by Nesterov [6]. Then the composite form, \( \Omega(w) \) plus the smoothed variant of \( g^*(Aw) \), fits the form of AGM-EF and can be solved in \( w \) (primal), \( \alpha \) (dual) or primal-dual. Given a prescribed accuracy \( \epsilon \), \( g^* \) only needs to be smoothed to a fixed extent.

Smoothing \( g^* \) with decreasing smoothness. Nesterov [20] introduced a primal-dual method where \( g^* \) is smoothed with decreased smoothness (i.e. increased closeness to \( g^* \)). As a result, it tends to the optimal solution of \( D(\alpha) \) and \( J(w) \), instead of just attaining a prescribed accuracy \( \epsilon \).

No smoothing. Given the smoothness of the dual problem \( D(\alpha) \), AGM can be applied to maximize it and then convert \( \alpha_k \) into \( w_k \) by (22) and (35). No smoothing of \( g^* \) is needed in this case.

The next three subsections will describe these schemes in detail, with focus on the rates of convergence and how each iteration can be performed efficiently. Moreover, we provide intuitions on which scheme is more suitable. For brevity, we will only use AGM-EF-\( \infty \) with fixed \( L \) as an example, while similar results can be straightforwardly derived for AGM-EF-1 and adaptive \( L \). In this version of the paper, we illustrate all these ideas on Example 1 (SVM with bias).

5.1. Smoothing \( g^* \) to a fixed level

A key technique introduced by Nesterov [6] was to tightly approximate the nonsmooth part \( g^*(Aw) \) by a smooth surrogate. The idea of the approach originates from the Theorem 21 in Appendix A which connects the strong convexity of a function and \( l.c.g \) of its Fenchel dual. \( g^* \) is not \( l.c.g \) because \( g \) is not strongly convex, therefore to make \( g^* \) smooth a natural idea is to add to \( g \) a strongly convex function \( d_2 \) on \( Q_2 \) and then dualize it:

\[ g^*_\mu(u) := (g + \mu d_2)^*(u) = \sup_{\alpha \in Q_2} \{ (\alpha, u) - g(\alpha) - \mu d_2(\alpha) \} . \]  

Here \( \mu \geq 0 \) and \( d_2 \) is assumed to be \( d_2 \)-sc wrt a norm on \( Q_2 \). By proper centering, \( d_2 \) can be assumed to satisfy

\[ \min_{\alpha \in Q_2} d_2(\alpha) = 0. \]

Let us further define

\[ \alpha_0 = \text{argmin}_{\alpha \in Q_2} d_2(\alpha), \quad D := \max_{\alpha \in Q_2} d_2(\alpha). \]

The main restriction of this approach is that \( D \) must be well bounded. Using the definition in (53) we can easily characterize the uniform tightness of the approximation: for all \( u \in Q_2 \),

\[ g^*(u) - \mu D \leq g^*_\mu(u) \leq g^*(u). \]  

\[ \text{We can also use the more general form of strong convexity as in Definition 1. Here we use the conventional definition for simplicity.} \]
Furthermore, the L.C.G constant of $g^*_\mu(Aw)$ in $w$ wrt the norm on $Q_1$ can be estimated as follows. By Theorem 21, $g^*_\mu$ is $(\mu \sigma_2)^{-1}$-L.C.G wrt the dual norm on $Q_2$. So we can apply the chain rule:

$$\frac{\partial}{\partial w} g^*_\mu(Aw) = \frac{\partial}{\partial w} (\nabla g^*_\mu(Aw)) = \nabla g^*_\mu(Aw).$$

That is, $g^*_\mu(Aw)$ is L.C.G in $w$ with constant $L_g(\mu) \leq \frac{\|A\|^2}{\mu \sigma_2}$. \hfill (55)

**Example 1:** smoothing the hinge loss. The hinge loss $[1 - w]_+$ is the dual of $g(\alpha) = \alpha$ for $\alpha \in [-1, 0]$ and $\infty$ elsewhere. Adding $\frac{\mu}{2} \alpha^2$ to $g$ and dualizing it, we get

$$g^*_\mu(w) = \begin{cases} 0 & \text{if } w \geq 0, \\ \frac{(1-w)^2}{2\mu} & \text{if } w \in [1 - \mu, 1], \\ 1 - w - \frac{1}{\mu} & \text{if } w \leq 1 - \mu. \end{cases}$$

Some smoothed hinge loss $g^*_\mu(w)$ with various $\mu$ are plotted in Figure 1.

**Example 2:** smoothing max into soft max. In the entropy regularized LPBoost, $g^*(s) = \text{max}_i s_i$ and $g(u) = 0$ if $S_i$ and $\infty$ otherwise. Then adding prox-function $\sum_i s_i \ln s_i$ to $g$ and dualizing it, we get

$$g^*_\mu(s) = \mu \ln \sum_i \exp \left( \frac{s_i}{\mu} \right).$$

When $\mu \to 0$, this soft max recovers max.

With the smoothed $g^*_\mu$ in place, we now discuss how to find an $\epsilon$ accurate solution to $J(w)$ by three different schemes: primal $(w)$, dual $(\alpha)$, and primal-dual.

5.1.1. Solving in the primal $w$.

We will use $g^*_\mu$ to define a new objective function

$$J_\mu(w) := \Omega(w) + g^*_\mu(Aw) = \Omega(w) + \max_{\alpha \in Q_2} \{ \langle Aw, \alpha \rangle - g(\alpha) - \mu d_2(\alpha) \}. \hfill (56)$$

Since $J_\mu(w) \leq J(w)$ for all $w$, to make sure that an $\epsilon$ accurate solution to $J_\mu$ is a $2\epsilon$ accurate solution to $J$, a sufficient condition is that their deviation be upper bounded everywhere by $\epsilon$, i.e. $\text{max}_w J(w) - J_\mu(w) < \epsilon$. By (54), this is guaranteed if $\mu$ is small enough

$$\mu \leq \frac{\epsilon}{D}. \hfill (57)$$

Plugging (57) into (55), we obtain that the L.C.G constant of $g^*_\mu(Aw)$ is at most $\frac{\|A\|^2}{\sigma_2 \sigma_2(k+1)^2}$. Let $w^* = \text{argmin}_w J(w)$. Bearing in mind that $\Omega$ is $\lambda$-sc, AGM-EF-$\infty$ is readily applicable to $J_\mu(w)$ and the following rate of convergence can be inferred from Theorem 6:

$$J_\mu(w_k) - J_\mu(w^*) \leq \Delta(w^*, u_0) \min \left\{ \frac{4D \|A\|^2}{\sigma_1 \sigma_2 (k+1)^2}, \frac{4D \|A\|^2}{\sigma_1 \sigma_2^2 \epsilon} \left( 1 + \sqrt{\frac{\sigma_1 \sigma_2 \lambda \epsilon}{4D \|A\|^2}} \right)^{-2k+2} \right\}.$$\hfill (58)

Once $J_\mu(w_k) - J_\mu(w^*) \leq \epsilon$, we must have

$$J(w_k) - J(w^*) \leq J_\mu(w_k) + \mu D - J_\mu(w^*) \leq 2\epsilon.$$\hfill (59)

Therefore, we obtain the following theorem.

**Theorem 19.** For any given $\epsilon > 0$, setting $\mu$ by the equality in (57) and applying AGM-EF-$\infty$ to $J_\mu(w)$, we can guarantee that $w_k$ is a $2\epsilon$ accurate solution of $J(w)$ as long as

$$k \geq \min \left\{ 1 \left( \frac{1}{\epsilon} \sqrt{\frac{4D \|A\|^2}{\sigma_1 \sigma_2}} \Delta(w^*, u_0), \right. \left. \frac{1}{\epsilon} \frac{4D \|A\|^2}{\sigma_1 \sigma_2^2 \epsilon} \right) \left/ \ln \left( 1 + \sqrt{\frac{\sigma_1 \sigma_2 \lambda \epsilon}{4D \|A\|^2}} \right) \right\}. \hfill (58)$$

Note $\ln(1+\epsilon) \approx \epsilon$ when $\epsilon$ is close to 0, so the denominator in the second term becomes $O(\sqrt{\epsilon})$ and overall the second term is approximately $O \left( \frac{1}{\sqrt{\epsilon}} \ln \frac{1}{\epsilon} \right)$. The
first term does not depend on \( \lambda \). Note also that this bound does not explicitly depend on the diameter of \( Q_1 \) which is infinity in many cases. A closer look shows that \( \Delta(w^*, u_0) \) hides the dependence on \( \lambda \). With a small regularization parameter \( \lambda \), \( \Delta(w^*, u_0) \) may be large and could approach infinity when \( \lambda \) tends to 0.

Unfortunately, the bound on the duality gap in (23) does use the diameter of \( Q_1 \), and it cannot be replaced by \( \Delta(w^*, u_0) \) as in Theorem 19. Therefore, we do lose a termination criteria. Fortunately, this problem in duality gap can be avoided if we optimize in \( \alpha \). Before describing it in detail, let us illustrate the above procedure on training the SVM with bias.

Here, choose \( d_1 \) and \( d_2 \) as the Euclidean norm square and the norms on \( Q_1 \) and \( Q_2 \) are both Euclidean norm. Then \( \|A\|^2 = \lambda_{\text{max}}(A^T A) = \lambda_{\text{max}}(XX^T) \) where \( \lambda_{\text{max}} \) stands for the maximum eigenvalue. \( \sigma_1 = \sigma_2 = 1 \). The diameter of \( Q_2 \) is \( D \leq n \frac{1}{\mu} = \frac{1}{\mu} \). For a given \( \epsilon \), set \( \mu = \epsilon n \) by (57). Suppose all \( x_i \) lie in the ball with Euclidean radius \( R \). Then \( \lambda_{\text{max}}(XX^T) \leq nR^2 \) and the second term in (58) is essentially

\[
O \left( \ln \frac{1}{\epsilon} \sqrt{\frac{4L_{\text{max}}(XX^T)}{\lambda \epsilon}} \right) \leq O \left( 2R \sqrt{\lambda} \ln \frac{1}{\epsilon} \right).
\]

Solving in the primal is also advantageous in terms of the condition number. When \( g^* \) is smoothed by small \( \mu \) or when the regularization parameter \( \lambda \) is small, the condition number \( c := L_g(\mu)/\lambda \) becomes very large. According to Theorem 6, the number of iterations to find an \( \epsilon \) accurate solution is the min of

\[
O \left( \log \frac{1}{\epsilon} \right) \quad \text{and} \quad O \left( \frac{L_g(\mu)}{\sqrt{\epsilon}} \right).
\]

So the linear convergence rate depends on \( c \) by \( O(\sqrt{c}) \), as opposed to \( O(c) \) in most linearly converging algorithms, e.g. gradient descent. Second, the min in Theorem 6 implies that when \( \lambda \) is very small and the objective is very poorly conditioned, the linear convergence will be automatically superseded by the \( 1/\sqrt{\epsilon} \) rate which has better “constant”. Some class of algorithms require manual rewiring in such a case, e.g. [25] and [35].

Finally, it is noteworthy that this method does not require \( g \) be l.c.g.

5.1.2. Solving in the dual \( \alpha \).

Similar to \( J_\mu \) in (56), we can also define a smoothed version of \( D(\alpha) \):

\[
D_\mu(\alpha) := -\mu d_2(\alpha) - g(\alpha) + \min_w \{ \Omega(w) + \langle Aw, \alpha \rangle \}
\]

\[
= -\mu d_2(\alpha) - g(\alpha) - \Omega^*( -A^T \alpha)
\]

which is to be maximized over \( \alpha \in Q_2 \). So we can pose \(-D_\mu(\alpha)\) in the composite form,

\[
f(\alpha) = g(\alpha) + \Omega^*( -A^T \alpha),
\]

to which AGM-EF-\( \infty \) and AGM-EF-1 can be applied. Since \( \Omega^* \) is 1/l.c.g, \( f(\alpha) \) must be l.c.g with constant

\[
L_f = \frac{\|A\|^2}{\lambda} + L_g,
\]

where \( L_g \) is the l.c.g constant of \( g \). \( \Psi(\alpha) = \mu d_2(\alpha) \),

Once \( J_\mu(w_k) - D_\mu(\alpha_k) \leq \epsilon \), it is ensured that

\[
J(w_k) - \min_w J(w) \leq J_\mu(w_k) + \mu D - \max_{\alpha \in Q_2} D(\alpha)
\]

\[
\leq J_\mu(w_k) + \epsilon - D(\alpha_k)
\]

\[
\leq J_\mu(w_k) + \epsilon - D_\mu(\alpha_k) \leq 2\epsilon.
\]

So we conclude the following theorem.

**Theorem 20.** For any given \( \epsilon > 0 \), setting \( \mu \) by the equality in (57) and applying the primal-dual scheme in Section 3.3 to \(-D_\mu \) and \(-J_\mu \), we can guarantee that \( w_k \) is a \( 2\epsilon \) accurate solution of \( J(w) \) as long as

\[
k \geq \min \left\{ \frac{1}{\sqrt{\epsilon}} \sqrt{\frac{4M(\|A\|^2 + 4L_g)}{\lambda \sigma_2}} - 1, \right. \]

\[
1 + \frac{1}{2} \ln \left( \frac{4M(\|A\|^2 + 4L_g)}{\lambda \sigma_2 \epsilon} \right)
\]

where \( M := \max_{\alpha \in Q_2} \Delta(\alpha, u_0) \).

It is important to note that this scheme requires \( g \) be l.c.g. While solving in the primal does not make such a requirement.
Let us apply the scheme to SVM with bias, and use the same choice of norm and prox-function as before. Now \( L_g = 0 \) and \( M = 1/n \). Using the approximation \( \ln(1 + x) \approx x \) when \( |x| \ll 1 \), (61) becomes

\[
k \geq \min \left\{ \frac{2R}{\sqrt{\lambda e}} - 1, 1 + \frac{R}{\sqrt{\lambda e}} \ln \left( \frac{4R^2}{\lambda e} \right) \right\}.
\]

As a final note, the way we smooth the empirical risk is different from [36] which changes hinge loss into square hinge loss or higher order. Our method has a smoothing parameter which trades smoothness for the tightness of the approximation. In contrast, the square hinge loss is just a heuristic approximation and no bound is available in optimization for its solution.

### 5.2. Smoothing \( g^* \) with decreasing smoothness

A typical primal-dual solver for the objectives in (37) and (38) is the excessive gap technique \([\text{EGT}, 20]\). One concrete application is [37] where EGT is used to solve the above Example 4 (M3N and CRF). Unfortunately, EGT forces a fixed way to initialize \( w_0 \) and \( \alpha_0 \). This is very inconvenient for homology and other warm-start techniques which utilize the closeness of solutions under small perturbations of the problem parameter \((e.g. \lambda)\).

### 5.3. No smoothing of \( g^* \)

Since we assume \( g \) is l.c.g and \( \Omega \) is \( \lambda \)-sc, so the dual (39) is l.c.g and AGM-EF-\( \infty \) is applicable. Since our ultimate goal is to minimize \( J(w) \) we adopt the primal-dual scheme in Section 3.3. The l.c.g constant of \( D \) is exactly the \( L_f \) in (60). Treating \( -D \) and \( -J \) as the \( J \) and \( D \) therein respectively, we get

\[
J(w_k) - D(\alpha_k) \leq \frac{4M(||A||^2 + \lambda L_g)}{\lambda \sigma_d(k+1)^2}.
\]

When applied to SVM with bias where \( M = 1/n \) and \( L_g = 0 \), we get that \( J(w_k) - D(\alpha_k) < \epsilon \) for all

\[
k \geq \frac{2R}{\sqrt{\lambda e}} - 1.
\]

When comparing the rates, it is important to bear in mind that machine learning problems usually do not need a high accuracy solution and so \( \epsilon = 10^{-2} \) or \( 10^{-3} \) might suffice. In many cases, \( \lambda \) will be set to very small such as \( 10^{-6} \). Therefore \( \frac{1}{\epsilon} \) can be much smaller than \( \frac{1}{\lambda} \). Also, we are currently bounding \( ||A||^2 \) by \( nR^2 \) which can be very loose in practice. The dependence of \( \Delta(w^*, u_0) \) on \( \lambda \) is not clear either. Finally in practice when solving in the dual, the box constraints in SVM can cause considerable waste of gradient computation. Therefore the rates above just provide limited guidance and the most appropriate optimization strategy has to be picked empirically.

### 5.4. Efficient computation of the gradient

So far, we have ignored the computational complexity per iteration which is dominated by two operations: computing the gradient and minimizing the model \( \psi_k \) in AGM-EF-\( \infty \) (or \( q_k \) in AGM-EF-1). We first show in this subsection that the gradient in all the above examples can be computed efficiently. Indeed, the gradients needed are \( \frac{\partial}{\partial w} g^*_\mu(Aw) \) and \( \frac{\partial}{\partial \alpha} \Omega^*(-A^T \alpha) \), with the former always being more challenging. So we focus on calculating \( \frac{\partial}{\partial w} g^*_\mu(Aw) \).

By chain rule, \( \frac{\partial}{\partial w} g^*_\mu(Aw) = A^T \nabla g^*_\mu(Aw) \). Using [47, Theorem X.1.4.4], \( \nabla g^*_\mu(u) \) can be computed by

\[
\nabla g^*_\mu(u) = \arg \max_{\alpha \in Q_2} (u, \alpha) - g(\alpha) - \mu d_2(\alpha). \tag{62}
\]

In the case of multivariate score (43) and (44), the dimension of the domain of \( g \) is exponentially high in the number of training examples, and therefore it will be intractable to first compute \( \nabla g^*_\mu(Aw) \) and then pre-multiply it with \( A^T \) (\( A \) has exponentially many rows). Similar tractability issues appear in learning with structured outputs as in M3N. Below we present a dynamic programming based algorithm, which costs \( O(n^2) \) time and space complexity to calculate \( A^T \nabla g^*_\mu(Aw) \) for

\[
d_2(\alpha) = \sum_i \alpha_i \ln \alpha_i.
\]

In this case, the optimization problem in (62) is

\[
\min_{\alpha \in Q_2} \mu \sum_{y'} \alpha_{y'} \ln \alpha_{y'} - n \sum_{y'} \Delta(y', y) \alpha_{y'} - \sum_{y'} u_{y'} \alpha_{y'}.
\]

Noting that the \( y'- \)th row of \( A \) is \( \varphi^\top_{y'} := \sum_{i} (y'_i - y_i)x_i^\top \), we get \( u_{y'} = \varphi^\top_{y'} w = \sum_{i} (y'_i - y_i)x_i^\top w \). Following the standard procedures \((e.g. [37, Lemma 8])\), the optimal solution can be written as

\[
\alpha_{y'}^* := \frac{1}{nZ} \exp \left( -\frac{1}{\mu} \sum_i y'_i x_i^\top w + \frac{n}{\mu} \Delta(y', y) \right),
\]

where \( Z := \sum_{y'} \exp \left( -\frac{1}{\mu} \sum_i y'_i x_i^\top w + \frac{n}{\mu} \Delta(y', y) \right). \)

So \( \alpha_{y'}^* \) can be interpreted as a distribution over \( y' \).
Regularized Risk Minimization by Nesterov’s Accelerated Gradient Methods

![Diagram showing path weight interpretation of the normalizer Z and the marginal distributions p(y'_k).](image)

(normalized to \(\frac{1}{n}\) rather than 1). Then

\[
\frac{\partial}{\partial w} g^\alpha(Aw) = \sum_{y'} \alpha^\alpha_{y'} \varphi_{y'} - \sum_{y'} \sum_i (y'_i - y_i) x_i
\]

\[
= -2 \sum_i y_i x_i \sum_{y' \sim y_i} \alpha^\alpha_{y'}
\]

\[
= -2 \sum_i p(y'_i = -y_i) y_i x_i,
\]

where \(y' \sim -y_i\) means summing up all \(y'\) whose \(i\)th element \(y'_i\) equals \(-y_i\). So \(\sum_{y' \sim y_i} \alpha^\alpha_{y'}\) is exactly the marginal probability \(p(y'_i = -y_i)\) under the joint distribution \(\alpha^\alpha_{y'}\). Now we show how to compute the marginal distributions efficiently.

Unlike the inference in graphical models, there is no clique factorization in \(y'\). Fortunately, \(\{y'_i\}\) are coupled only through the loss \(\Delta(y', y)\) which in turn depends only on two “sufficient statistics” of \(y'\): false negative \(b\) and false positive \(c\). For simplicity, we sometimes also write \(\Delta(y', y)\) as \(\Delta(b, c)\). Without loss of generality, assume the positive training examples are the first \(n_+\) ones \(y_1 = \ldots = y_{n_+} = 1\), and the negative examples are the last \(n - n_+\) ones \(y_{n_+ + 1} = \ldots = y_n = -1\). Denote \(y'_+ := (y'_1, \ldots, y'_{n_+})^T\) and \(y'_- := (y'_{n_+ + 1}, \ldots, y'_n)^T\). \(y'_+ \sim b\) represents that \(y'_+\) commits \(b\) false negatives, i.e. \(\sum_{i=1}^{n_+} \delta(y'_i = -1) = b\). \(y'_- \sim c\) represents that \(y'_-\) commits \(c\) false negatives, i.e. \(\sum_{i=n_+ + 1}^{n} \delta(y'_i = 1) = c\). For simplicity, denote

\[
c_k := \exp\left(\frac{1}{\mu} x_k^T w\right).
\]

Let us first compute the normalizer \(Z\) as follows.

\[
Z = \sum_{b=0}^{n_+} \sum_{c=0}^{n_+ - b} \sum_{y' \sim \sim -c} \left(\frac{1}{\mu} \sum_{i=1}^{n} y'_i x_i^T w + \frac{n}{\mu} \Delta(y', y)\right)
\]

\[
= \sum_{b=0}^{n_+} \sum_{c=0}^{n_+ - b} \exp\left(\frac{n}{\mu} \Delta(b, c)\right) \sum_{y' \sim \sim -b} \exp\left(\frac{1}{\mu} \sum_{i=1}^{n} y'_i x_i^T w\right)
\]

Therefore, once we have \(V_+(b)\) for all \(b \in [n_+]\) and \(V_-(c)\) for all \(c \in [n_-]\), then \(Z\) can be computed in \(n_+ n_-\) steps. For simplicity we only show to compute \(V_+(b)\), and \(V_-(c)\) can be computed in exactly the same way.

For each fixed \(b\), \(V_+(b)\) can be equivalently reformulated by Figure 2. Each node \((k, f)\) represents that \(y'\) has committed \(f\) false negatives in the first \(k\) examples: \(\sum_{i=1}^{k} \delta(y'_i = -1) = f\). Each node is connected to two nodes on its right: \((k + 1, f + 1)\) and \((k + 1, f)\). The former corresponds to \(y'_{k+1} = -1\), i.e. one more false negative is committed. So we attach to the diagonal edge a weight \(\exp\left(-\frac{1}{\mu} x_{k+1}^T w\right) = c_k^{-1}\). The latter means \(y'_{k+1} = 1\) and the false negative is not incremented. So the horizontal edge is attached with weight \(c_{k+1}\). A path from \((k, f)\) to \((k', f')\) \((k \leq k'\) and \(f \leq f'\)) is a sequence of nodes moving from \((k, f)\) to \((k', f')\) along the edges of the graph: \((k, f_0) \rightarrow (k + 1, f_1) \rightarrow \ldots \rightarrow (k + s, f_s) = (k', f')\) where \(s = k' - k\) and \(f_{i+1} - f_i = 0\) or \(1\). The weight of a path is defined as the product of the weight of all edges on that path.

Clearly \(V_+(b)\) is equal to the total weight of all paths from \((0, 0)\) to \((n_+, b)\). To compute it, define \(\alpha_k(v)\) as the total weight of all paths from \((0, 0)\) to \((k, v)\). Then it is not hard to see the following recursion for all \(k = 1, \ldots, n_+\) and \(v = 0, 1, \ldots, k\):

\[
\alpha_k(v) = \frac{1}{c_k} \alpha_{k-1}(v - 1) + c_k \alpha_{k-1}(v),
\]

where \(\alpha_k(1) := 0\) and \(\alpha_k(k + 1) := 0\) for all \(k\). Algorithm 5 computes \(V_+(b) = \alpha_{n_+}(b)\) for all \(b \in [n_+]\). Clearly the computational cost is \(O(n_+^2)\). If we only
need \( V_+(b) \) then the space complexity is \( O(n_+) \). But later we will keep all \( \alpha_k(v) \) so we keep \( O(n_+^2) \) memory. Taking into account the similar cost for \( V_-(c) \), the total spatial and computational cost is both \( O(n^2) \).

To compute the marginal distributions \( p(y_k') \) we need a backward propagation. For example let us consider \( p(y_k' = 1) \) for \( k \in [n+] \), and the case of \( k > n_+ \) (negative examples) can be dealt with similarly. By the definition of \( \alpha_k \), it suffices to compute

\[
Z_k := \sum_{y': y_k' = 1} \exp \left( \frac{1}{\mu} \sum_i y_i' x_i^\top w + \frac{n}{\mu} \Delta(y', y) \right)
\]

\[
= \sum_{b=0}^{n_+} \sum_{c=0}^{n_+} \exp \left( \frac{n}{\mu} \Delta(b, c) \right) \sum_{y': y_k' = 1} \exp \left( \frac{1}{\mu} \sum_{i=1}^{n_+} y_i' x_i^\top w \right) 
\]

\[
\cdot \sum_{i=1}^{n_+} \exp \left( \frac{1}{\mu} \sum_{i=1}^{n_+} y_i' x_i^\top w \right)
\]

\[
= \sum_{b=0}^{n_+} \sum_{c=0}^{n_+} \exp \left( \frac{n}{\mu} \sum_{i=1}^{n_+} y_i' x_i^\top w \right)
\]

\[
\cdot \sum_{c=0}^{n_+} \exp \left( \frac{n}{\mu} \Delta(b, c) \right) V_-(c).
\]

Since \( V_-(c) \) available from forward propagation, \( \{y_k(\cdot)\} \) can be computed in \( O(n^2) \) time. So the only problem left is to compute \( T^k_+(b) \). \( T^k_+(b) \) has a very intuitive interpretation in Figure 2: the total weight of all paths from \((0, 0)\) to \((n_+, b)\) with the \( k \)-th step (i.e. between the horizontal coordinate \( k - 1 \) and \( k \)) going horizontal (not diagonal). Let \( \beta^k_+(v) \) denote the total weight of all paths from \((k, v)\) to \((n_+, b)\). Then

\[
T^k_+(b) = \sum_{v=0}^{n_+} \alpha_{k-1}(v) c_k \beta^k_+(v).
\]
5.5.1. Diagonal quadratic constrained to a box and a hyperplane

When AGM-EF is applied to solve the dual optimization problem \( D(\alpha) \) for SVM in (41), each iteration needs to solve the model subject to \( Q_2 \). This can be reduced to a box constrained diagonal QP with a single linear equality constraint:

\[
\min \frac{1}{2} \sum_{i=1}^{n} d_i^2 (\alpha_i - m_i)^2 \quad \text{(64)}
\]

\[
s.t. \quad l_i \leq \alpha_i \leq u_i, \quad \forall i \in [n]; \quad \sum_{i=1}^{n} \sigma_i \alpha_i = z.
\]

Similarly, when solving in the primal with smoothing in (56), the gradient query also involves an optimization in this form. In this section, we focus on the following the QP in (64). The algorithm we describe below stems from [38] and finds the exact optimal solution in \( O(n) \) time, faster than the \( O(n \log n) \) complexity in [39]. [39] also proposes a median finding based algorithm which has linear time complexity in expectation. In contrast, our method is deterministic and linear. Liu and Ye [40] tackle this problem too, but they use the mean bisection and apply Newton’s method to find a solution up to an inexact prespecified accuracy \( \delta \). The resulting total cost is \( O(n \log n) \).

Without loss of generality, we assume \( l_i < u_i \) and \( d_i \neq 0 \) for all \( i \). Also assume \( \sigma_i \neq 0 \) because otherwise \( \alpha_i \) can be solved independently. To make the feasible region nonempty, we also assume

\[
z \geq \sum \sigma_i (\delta(\sigma_i > 0) l_i + \delta(\sigma_i < 0) u_i)
\]

and

\[
z \leq \sum \sigma_i (\delta(\sigma_i > 0) u_i + \delta(\sigma_i < 0) l_i).
\]

With a simple change of variable \( \beta_i = \sigma_i (\alpha_i - m_i) \), the problem (64) is simplified as

\[
\min \frac{1}{2} \sum_{i=1}^{n} d_i^2 \beta_i^2
\]

\[
s.t. \quad l_i' \leq \beta_i \leq u_i', \quad \forall i \in [n]; \quad \sum_{i=1}^{n} \beta_i = z',
\]

where \( d_i^2 = \frac{d_i^2}{\sigma_i^2} \), \( l_i' = \begin{cases} \sigma_i (l_i - m_i) & \text{if } \sigma_i > 0, \\ \sigma_i (u_i - m_i) & \text{if } \sigma_i < 0 \end{cases} \), \( u_i' = \begin{cases} \sigma_i (u_i - m_i) & \text{if } \sigma_i > 0, \\ \sigma_i (l_i - m_i) & \text{if } \sigma_i < 0 \end{cases} \), and \( z' = z - \sum \sigma_i m_i \).

Write out its partial Lagrangian:

\[
\min_{\beta_i \in [l_i', u_i']} \max_{\lambda, \delta} \sum_{i=1}^{n} \frac{1}{2} d_i^2 \beta_i^2 - \lambda \left( \sum_{i=1}^{n} \beta_i - z' \right).
\]

Due to strong duality, we can swap the min and max:

\[
\max_{\lambda \in \mathbb{R}} \min_{\beta_i \in [l_i', u_i']} \sum_{i=1}^{n} \frac{1}{2} d_i^2 \beta_i^2 - \lambda \left( \sum_{i=1}^{n} \beta_i - z' \right)
\]

\[
= \max_{\lambda \in \mathbb{R}} \sum_{i=1}^{n} \min_{\beta_i \in [l_i', u_i']} \left( \frac{1}{2} d_i^2 \beta_i^2 - \lambda \beta_i \right) + \lambda z'
\]

\[
\Leftrightarrow \min_{\lambda \in \mathbb{R}} \sum_{i=1}^{n} \max_{\beta_i \in [l_i', u_i']} \left( \frac{1}{2} d_i^2 \beta_i^2 + \lambda \beta_i \right) - \lambda z'
\]

\[
=: H_i(\lambda)
\]

Clearly, the optimal \( \beta_i^*(\lambda) \) in the definition of \( H_i(\lambda) \) can be solved analytically, and this gives

\[
H_i(\lambda) = \begin{cases} 
- \frac{1}{2} d_i^2 u_i^2 + \lambda u_i' & \text{if } \lambda > u_i' \frac{d_i^2}{\sigma_i^2} \\
- \frac{1}{2} d_i^2 l_i^2 + \lambda l_i' & \text{if } \lambda < l_i' \frac{d_i^2}{\sigma_i^2}
\end{cases}
\]

with

\[
\beta_i^*(\lambda) = \begin{cases} 
u_i & \text{if } \lambda > u_i' \frac{d_i^2}{\sigma_i^2} \\
\frac{l_i'}{2d_i^2} & \text{if } \lambda < l_i' \frac{d_i^2}{\sigma_i^2}
\end{cases}
\]

To minimize the objective in (65) as a function of \( \lambda \), we notice that \( H_i(\lambda) \) is convex and differentiable. Thus, the minimizer of (65) is exactly the root of its gradient. Note the gradient of \( H_i \):

\[
h_i(\lambda) = \begin{cases} 
u_i & \text{if } \lambda > u_i' \frac{d_i^2}{\sigma_i^2} \\
\frac{l_i'}{2d_i^2} & \text{if } \lambda < l_i' \frac{d_i^2}{\sigma_i^2}
\end{cases}
\]

See Figure 3 for the plot of \( h_i(\lambda) \). So we need to find
the root of the gradient of (65):
\[ f(\lambda) := \sum_{i=1}^{n} h_i(\lambda) - z' = 0. \] (66)

Note that \( h_i(\lambda) \) is a monotonically increasing function of \( \lambda \), so the whole \( f(\lambda) \) is monotonically increasing in \( \lambda \). Since \( f(\infty) \geq 0 \) by \( z' \leq \sum u'_i \) and \( f(-\infty) \leq 0 \) by \( z' \geq \sum l'_i \), the root must exist. Considering that \( f \) has at most \( 2n \) kinks (nonsmooth points) and is linear between two adjacent kinks, the simplest idea is to sort \( \{d^2 u'_i, d^2 l'_i : i \in [n]\} \) into \( s^{(i)} \leq \ldots \leq s^{(2n)} \). If \( f(s^{(i)}) \) and \( f(s^{(i+1)}) \) have different signs, then the root must lie between them and can be easily found because \( f \) is linear in \( [s^{(i)}, s^{(i+1)}] \). This algorithm takes at least \( O(n \log n) \) time because of sorting.

However, this cost can be reduced to \( O(n) \) by making use of the fact that the median of \( n \) (unsorted) elements can be found in \( O(n) \) time. Notice that due to the monotonicity of \( f \), \( f \) evaluated at the median of a set \( S \) is exactly the median of function values, i.e., \( f(\text{MED}(S)) = \text{MED}\{f(x) : x \in S\} \). Algorithm 7 shows the binary search. Let \(|S|\) denote the cardinality of \( S \). The while loop must terminate in order \( \log_2(2n) \) iterations because in each iteration the cardinality of set \( S \) is reduced to at most \( \frac{|S|}{2} + 1 \) (we will call it “almost halves”). So if \( f(m) \) can be evaluated in \( O(|S|) \) time, then the time complexity of each iteration is linear in \( |S| \), and the total complexity of Algorithm 7 is \( O(n) \). Step 7 and 9 ensure that \(|S| = 2 \) at step 12.

The evaluation of \( f(m) \) potentially involves summing up \( n \) terms as in (66). However by carefully aggregating the slope and offset, this can be reduced to \( O(|S|) \) too. In more detail, let us first consider all the possible locations of \( \min S \) and \( \max S \) on \( h_i(\lambda) \).

**Algorithm 7** \( O(n) \) algorithm to find the root of \( f(\lambda) \). Do not allow duplicate points in \( S \).

1: Initialize kink set \( S \leftarrow \{d^2 u'_i, d^2 l'_i : i \in [n]\} \). Remove duplicates if any.
2: while \(|S| > 2\) do
3: Find the median of \( S \): \( m \leftarrow \text{MED}(S) \)
4: if \( f(m) = 0 \) then
5: Return \( m \).
6: else if \( f(m) > 0 \) then
7: \( S \leftarrow \{x \in S : x \leq m\} \).
8: else
9: \( S \leftarrow \{x \in S : x \geq m\} \).
10: end if
11: end while
12: Return \( \frac{[f(u) - f(l)]}{f(u) - f(l)} \) if \( S = \{l, u : f(l) \neq f(u)\} \), or any value in \([l, u]\) if \( S = \{l < u : f(l) = f(u)\} \).

![Figure 4. All possible locations of \( \min S \) and \( \max S \) on \( h_i(\lambda) \).](image-url)
can there be? By Figure 4, these $h_i$ all contribute at least one kink point in $S$ (state (a) contributes two). If $\{d^2_i l'_i, d^2_i u'_i : i \in [n]\}$ are distinct, then the points in $S$ have one-to-one correspondence to the kink points of $h_i$. Therefore, the number of $h_i$ in undetermined states must be upper bounded by the size of $S$. Since the size of $S$ almost halves in each iteration, so is number of $h_i$ in undetermined states. As a result, the cost for computing $f(m)$ halves too. Overall, running Algorithm 7 to completion, the total time spent on evaluating $f(m)$ in step 4 is $O(n)$.

The analysis becomes a bit more complicated when $\{d^2_i l'_i, d^2_i u'_i : i \in [n]\}$ contains duplicate points. In this case, one point in $S$ may correspond to kink points of multiple $h_i$, and so the above argument can no longer be used to upper bound the number of $h_i$ in undetermined states. The simplest patch is to add small perturbations to the duplicate points and make them different. A more principled solution is given in Algorithm 8. The key idea is to allow duplicates in $S$, and replace $S \leftarrow \{x \in S : x \leq m\}$ in step 7 of Algorithm 7 by $S \leftarrow \{x \in S : x < m\}$ (and similarly step 9). An additional level of if-then-else check is introduced so as not to miss out the solution. Clearly, the size of $S$ still halves in Algorithm 8. More importantly, because we do allow the duplicates in $S$, so the size of $S$ is an upper bound of the number of $h_i$ which is in undetermined states. Therefore, the cost for computing $f(m)$ and $f(y)$ halves through iterations, and the total time spent on evaluating $f(m)$ and $f(y)$ is $O(n)$.

Note that the duplication removal in Algorithm 8 actually cannot be done in $O(n)$ time, and is subject to numerical precision. In our experiment, we used Algorithm 8 which does not remove duplicates. The correctness is easy to prove, and in practice there is almost no duplicates and it works very well.

### Algorithm 8 $O(n)$ algorithm to find the root of $f(\lambda)$. Allow duplicate kink points in $S$.

1: Initialize kink set $S \leftarrow \{d^2_i l'_i, d^2_i u'_i : i \in [n]\}$. Keep duplications and so $|S| = 2n$.
2: while $|S| > 2$ do
3: Find the median of $S$: $m \leftarrow \text{MED}(S)$.
4: if $f(m) = 0$ then
5: Return $m$.
6: else if $f(m) > 0$ then
7: Find $y \leftarrow \text{MED}(S \cup \{m\})$.
8: if $f(y) > 0$ then
9: $S \leftarrow \{x \in S : x < m\}$.
10: else
11: $S \leftarrow \{y, m\}$. // Root lies in $[y, m]$, so exit the while loop immediately.
12: end if
13: else
14: Find $y \leftarrow \text{MIN}(S \cup \{m\})$.
15: if $f(y) < 0$ then
16: $S \leftarrow \{x \in S : x > m\}$.
17: else
18: $S \leftarrow \{m, y\}$. // Root lies in $[m, y]$, so exit the while loop immediately.
19: end if
20: end if
21: end while
22: Return $\frac{f(l) - u f(l)}{f(u) - f(l)}$ if $S = \{l, u : f(l) \neq f(u)\}$, or any value in $[l, u]$ if $S = \{l < u : f(l) = f(u)\}$.

### 5.5.2. Elastic Net

For the first type of elastic net (52), the composite optimization is easy thanks to the separability. The second type which uses constraints is much more challenging, and we show in this section how to solve this constrained optimization in linear time. Our approach is similar to the previous Section 5.5.1.

At each iteration of AGM-EF-∞ or AGM-EF-1, we need to solve

$$\min_{\lambda} \frac{\lambda}{\gamma} \left( \|w\|_1 + \frac{1}{2} \|w\|_2^2 \right) + \frac{L}{2} \|w - g_i\|^2.$$

Since all dimensions of $w$ are decoupled, each $w_i$ can be solved separately as a one dimensional optimization problem. In fact, its solution enjoys a simple closed form [41, p. 384]:

$$w^*_i = \begin{cases} \frac{L g_i - \gamma \lambda}{\lambda + L} & \text{if } \lambda < L g_i / \gamma \\ 0 & \text{if } \lambda \geq L g_i / \gamma \end{cases}.$$
A more difficult version of elastic net is based on constraints, where in each iteration one needs to solve
\[
\min_w \frac{1}{2} \| w - g \|^2 \quad \text{s.t.} \quad \gamma \| w \|_1 + \frac{1}{2} \| w \|_2^2 \leq \lambda. \tag{67}
\]
Clearly the optimal \( w_i \) has the same sign as \( g_i \), hence we can assume \( g_i \geq 0 \) without loss of generality. Next we follow the same idea as in Section 5.5.1 and reformulate (67) into a one dimensional root finding problem. First write out the Lagrangian:
\[
\min_{w} \max_{\lambda \geq 0} \frac{1}{2} \| w - g \|^2 + \lambda \left( \gamma \| w \|_1 + \frac{1}{2} \| w \|_2^2 - r \right)
\]
\[
\Leftrightarrow \max_{\lambda \geq 0} \min_w \frac{1}{2} \| w - g \|^2 + \lambda \left( \gamma \| w \|_1 + \frac{1}{2} \| w \|_2^2 - r \right)
\]
\[= f_\lambda(w) \]
where the equivalence is based on a simple check of Slater’s condition. For each fixed \( \lambda \), the optimal \( w \) can be found by setting the subgradient to \( 0 \).
\[
\frac{\partial}{\partial w_i} f_\lambda(w) = w_i - g_i + \lambda w_i + \lambda \gamma \cdot \begin{cases} 1 & \text{if } w_i > 0 \\ -1 & \text{if } w_i < 0 \\ [-1, 1] & \text{if } w_i = 0 \end{cases}
\]
Therefore, the optimal solution is
\[
w_i^* = \begin{cases} \frac{g_i - \lambda \gamma}{1 + \lambda} & \text{if } \lambda \leq g_i / \gamma \\ 0 & \text{if } \lambda > g_i / \gamma \end{cases}. \tag{69}
\]
Plugging it back to \( f_\lambda(w) \) we get the one dimensional optimization problem in \( \lambda \):
\[
H(\lambda) = -r \lambda \gamma + \sum_{i=1}^p \left( \frac{\lambda(\lambda \gamma^2 + g_i^2 + 2g_i \gamma)}{2(1 + \lambda)} \right) \quad \text{if } \lambda \leq g_i / \gamma
\]
\[
\quad + \sum_{i=1}^p \left( \frac{\lambda(\lambda \gamma^2 + 2g_i^2 + 2g_i \gamma^2)}{2(1 + \lambda)^2} \right) \quad \text{if } \lambda > g_i / \gamma
\]
It is easy to see that \( H(\lambda) \) is concave in \([-1, \infty) \). So its maximizer is 0 or the root of its derivative.
\[
H'(\lambda) = -r \gamma + \sum_{i=1}^p \left( \frac{-\gamma^2 \lambda^2 - 2\lambda^2 g_i + 2g_i \lambda \gamma + 2g_i^2}{2(\lambda + 1)^2} \right) \quad \text{if } \lambda \leq g_i / \gamma
\]
\[
\quad + \sum_{i=1}^p \left( \frac{-\gamma^2 \lambda^2 - 2\lambda^2 g_i^2 + 2g_i \lambda + 2g_i^2}{2(\lambda + 1)^2} \right) \quad \text{if } \lambda > g_i / \gamma
\]
\[
= \frac{1}{2(\lambda + 1)^2} h(\lambda)
\]
where
\[
h(\lambda) = -2\gamma r (\lambda + 1)^2 + \sum_{i=1}^p \left\{ -\gamma^2 (\lambda + 1)^2 + (\gamma + g_i)^2 \right\} \quad \text{if } \lambda \leq g_i / \gamma
\]
\[
\quad + \sum_{i=1}^p \left\{ 0 \right\} \quad \text{if } \lambda > g_i / \gamma
\]
Clearly \( h(\lambda) \) is monotonically decreasing in \([0, \infty) \). So \( H(\lambda) \) is maximized at 0 if \( h(0) \leq 0 \), i.e.
\[
r \geq \frac{p}{2} \gamma + \frac{1}{2} \gamma \sum_{i=1}^p (\gamma + g_i)^2.
\]
Otherwise, \( h(\lambda) \) has a root in \([0, \infty) \). Since it monotonically decreases, the binary search trick in Section 5.5.1 can also be applied here. Once it is determined that the optimal \( \lambda \) is less than a set of \( g_i \), these quadratics can be aggregated by summing up the \( \gamma (g_i + \frac{1}{\gamma})^2 \). Finally, \( w \) is recovered by (69).

### 5.6. Optimizing the Prox-function

When smoothing \( g^* \), we have often used prox-function \( d(x) = \sum_i x_i^2 \). However, it is possible to improve the condition number by using an optimized prox-function. This idea was used by [17] where the l.c.q constant of a quadratic \( \frac{1}{2}x^T Hx + \langle b, x \rangle \) (\( x \in \mathbb{R}^p \)) is upper bounded by \( p \) when the norm is chosen as \( \|x\| = \sum_i H_{ii} x_i^2 \), i.e. rescaling all dimensions.

Using this idea, we show in this section that a data dependent optimization of the prox-function can improve the condition number of the smoothed variant of the primal objective as discussed in Section 5.1.

Let us consider the following simple but illustrative example. Suppose \( Q_2 = [0, c]^n \), \( g(u) = -\sum_{i=1}^n a_i \). Denote \( A = (a_1, \ldots, a_n)^T \). We adopt a prox-function
\[
d(u) = \frac{1}{2} \sum_{i=1}^n b_i^2 u_i^2,
\]
and we can derive \( g_i^* = (g + \mu d)^* \). The diameter of \( Q_2 \) under \( d \) is
\[
D = \max_{x \in Q_2} d(u) = \frac{c^2}{2} \sum_i b_i^2. \tag{70}
\]
For any prescribed accuracy \( \epsilon > 0 \), we first choose \( \mu \) such that \( \mu D \leq \epsilon \), i.e. \( \mu \leq \frac{\epsilon}{D} \). Then our goal is to find the \( b_i \) which minimizes the Lipschitz constant of the gradient of \( g_i^*(Aw) \) wrt \( w \).

First compute \( g_i^*(Aw) \):
\[
g_i^*(Aw) = \sup_{u \in Q_2} \langle Aw, u \rangle + \sum_i u_i - \frac{\mu}{2} \sum_i b_i^2 u_i^2.
\]
It is easy to see that the optimal \( u_i^* \) is
\[
u_i^* = \text{MED} \left( 0, c, \frac{\langle a_i, w \rangle + 1}{\mu b_i^2} \right).
\]
where MED stands for the median. So the gradient of $g^*_\mu(Aw)$ wrt $w$ can be calculated by

$$\frac{\partial}{\partial w} g^*_\mu(Aw) = \sum_{i=1}^n g_i,$$

where $g_i = \begin{cases} 0 & \text{if } u^*_i = 0 \\ \frac{(a_i, w) + 1}{\mu b_i^2} a_i & \text{else} \end{cases}.$

So the Hessian of $g^*_\mu(Aw)$ in $w$ can only take value in

$$H_{\delta} = \frac{1}{\mu^2} \sum_i \frac{\delta_i}{b_i^2} a_i a_i^\top,$$

where $\delta_i \in \{0,1\}$.

Now for any $w_1, w_2 \in Q_1$, denote $l = \|w_1 - w_2\|$ and $v = (w_2 - w_1)/l$ (so $\|v\| = 1$). Denote $h(t) = \frac{\partial}{\partial w} g^*_\mu(A(w_1 + tv))$. So

$$\left| \frac{\frac{\partial}{\partial w} g^*_\mu(Aw_1) - \frac{\partial}{\partial w} g^*_\mu(Aw_2)}{\|w_1 - w_2\|} \right| = \frac{\|h(l) - h(0)\|}{l} \leq \frac{\|H_{\delta}v\|}{l} \leq \lambda_{\max}(H_{\delta}).$$

Here, (a) is by the mean value theorem with $\xi \in [0,l]$. (b) is by the chain rule and the $\delta$ for $H_{\delta}$ is determined by $\xi$. (c) is because for any real positive semi-definite matrix $H$, $\max_{\|v\|=1} \|Hv\| = \lambda_{\max}(H)$.

Clearly $\lambda_{\max}(H_{\delta})$ is maximized when all $\delta_i = 1$ and let us call it $H_{1}$. In conjunction with (70) and (57), we minimize $\lambda_{\max}(H_{1})$ wrt $b_i$:

$$\min_{b_i} \lambda_{\max}(H_{1}) = \min_{b_i} \frac{D}{\epsilon} \lambda_{\max} \left( \sum_i \frac{1}{b_i^2} a_i a_i^\top \right)$$

$$= \frac{c^2}{2\epsilon} \min_{b_i} \left\{ \left( \sum_i b_i^2 \right) \max_{\|v\|=1} v^\top \sum_i b_i^{-2} a_i a_i^\top v \right\}$$

$$= \frac{c^2}{2\epsilon} \max_{\|v\|=1} \left( \sum_i b_i^2 \right) \left( \sum_i b_i^{-2} (a_i^\top v)^2 \right) \tag{71}$$

$$= \frac{c^2}{2\epsilon} \max_{\|v\|=1} \left( \sum_i a_i^\top v \right)^2 \tag{72}$$

$$\Rightarrow \max_{\|v\|=1} \sum_i |a_i^\top v|^2 = \max_{\|v\|=1} v^\top \left( \sum_i a_i a_i^\top \right) v.$$

The solution is the eigenvector $v^*$ corresponding to the maximum eigenvalue of $\sum_i a_i a_i^\top$. Then $b_i^2$ can be recovered by using the optimality condition of Cauchy-Schwartz in (72):

$$b_i^2 = |a_i^\top v^*|.$$

Note [42] used the heuristic that $b_i^2 = ||a_i||^\infty$. We can also compare with the isotropic $d$, i.e., $b_i = 1$. Simply plug $b_i = 1$ into (71), and we get

$$\frac{c^2}{2\epsilon} \sum_i (a_i^\top v)^2$$

which must be greater than or equal to

$$\frac{c^2}{2\epsilon} \left( \sum_i |a_i^\top v| \right)^2$$

in (72) for all $v$. Therefore with a fixed $\epsilon$, our approach does possibly reduce the l.e.g constant of $g^*(Aw)$ in $w$. The maximum eigenvector can be found very efficiently by using the power iteration, and usually 5 to 6 iterations is enough.

6. Experimental Results

We will present the experimental result in a later version.

7. Discussion

A lot of efforts (e.g., [43, 44]) have been devoted to making Nesterov’s method online, i.e., use a stochastic gradient oracle and preserve the $1/\sqrt{T}$ rate of convergence for the expected gap. This however turns out hopeless as was shown by the lower bounds in [45, 46].

A. Concepts from Convex Analysis

The following four concepts from convex analysis are used in the paper.

Definition 2. Suppose a convex function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is finite at $w$. Then a vector $g \in \mathbb{R}^n$ is called a subgradient of $f$ at $w$ if, and only if,

$$f(w') \geq f(w) + \langle w' - w, g \rangle \quad \text{for all } w'.$$

The set of all such $g$ vectors is called the subdifferential of $f$ at $w$, denoted by $\partial f(w)$. For any convex function $f$, $\partial f(w)$ must be nonempty. Furthermore if it is a singleton then $f$ is said to be differentiable at $w$, and we use $\nabla f(w)$ to denote the gradient.

Definition 3. A convex function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is strongly convex with respect to a norm $\| \cdot \|$ if there exists a constant $\sigma > 0$ such that $f - \frac{\sigma}{2} \| \cdot \|^2$ is convex. $\sigma$ is called the modulus of strong convexity of $f$, and for brevity we will call $f$ $\sigma$-strongly convex.

Definition 4. Suppose a function $f : \mathbb{R}^n \rightarrow \mathbb{R}$ is differentiable on $Q \subseteq \mathbb{R}^n$. Then $f$ is said to have Lipschitz continuous gradient (l.c.g) with respect to a norm $\| \cdot \|$ if there exists a constant $L$ such that

$$\| \nabla f(w) - \nabla f(w') \| \leq L \| w - w' \| \quad \forall w, w' \in Q.$$

For brevity, we will call $f$ $L$-l.c.g.
Definition 5. The Fenchel dual of a function \( f : \mathbb{R}^n \rightarrow \mathbb{R} \), is a function \( f^* : \mathbb{R}^n \rightarrow \mathbb{R} \) defined by
\[
f^*(w^*) = \sup_{w \in \mathbb{R}^n} \{ (w, w^*) - f(w) \}
\]

Strong convexity and \( l.c.g \) are related by Fenchel duality according to the following lemma:

**Theorem 21** ([47, Theorem 4.2.1 and 4.2.2]).

1. If \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) is \( \sigma \)-strongly convex, then \( f^* \) is finite on \( \mathbb{R}^n \) and \( f^* \) is \( \frac{1}{\sigma} \)-l.c.g.
2. If \( f : \mathbb{R}^n \rightarrow \mathbb{R} \) is convex, differentiable on \( \mathbb{R}^n \), and \( L \)-l.c.g, then \( f^* \) is \( \frac{1}{L} \)-strongly convex.

Finally, the following lemma gives a useful characterization of the minimizer of a convex function.

**Lemma 22** ([47, Theorem 2.2.1]). A convex function \( f \) is minimized at \( w^* \) if, and only if, \( 0 \in \partial f(w^*) \). Furthermore, if \( f \) is strongly convex, then its minimizer is unique.
