We suggest the so-called bosonic seesaw mechanism in the context of a classically conformal $U(1)_{R-L}$ extension of the Standard Model with two Higgs doublet fields. The $U(1)_{R-L}$ symmetry is radiatively broken via the Coleman–Weinberg mechanism, which also generates the mass terms for the two Higgs doublets through quartic Higgs couplings. Their masses are all positive but, nevertheless, the electroweak symmetry breaking is realized by the bosonic seesaw mechanism. Analyzing the renormalization group evolutions for all model couplings, we find that a large hierarchy among the quartic Higgs couplings, which is crucial for the bosonic seesaw mechanism to work, is dramatically reduced toward high energies. Therefore, the bosonic seesaw is naturally realized with only a mild hierarchy, if some fundamental theory, which provides the origin of the classically conformal invariance, completes our model at some high energy, for example, the Planck scale. We identify the regions of model parameters which satisfy the perturbativity of the running couplings and the electroweak vacuum stability as well as the naturalness of the electroweak scale.

In the Standard Model (SM), the electroweak symmetry breaking is realized by the negative mass term in the Higgs potential, which seems to be artificial because there is nothing to stabilize the electroweak scale. If new physics takes place at a very high energy, e.g. the Planck scale, the mass term receives large corrections which are quadratically sensitive to the new physics scale, so that the electroweak scale is not stable against the corrections. This is the so-called gauge hierarchy problem. It is well known that supersymmetry (SUSY) can solve this problem. Since the mass corrections are completely canceled by the SUSY partners, no fine-tuning is necessary to reproduce the electroweak scale correctly, unless the SUSY breaking scale is much higher than the electroweak scale. On the other hand, since no indication of SUSY particles has been obtained in the large hadron collider (LHC) experiments, one may consider other solutions to the gauge hierarchy problem without SUSY.

In this direction, recently a lot of works have been done in models based on a classically conformal symmetry. There are $U(1)$ gauge extension [1–23], and non-Abelian gauge extension, in which conformal symmetry is broken by radiative corrections [15,24–28] and strong dynamics [29–37]. In addition, there are also non-gauge extended models [see Ref. [38] and therein].\textsuperscript{1} This direction is based on the argument by Bardeen [39] that the quadratic divergence in the Higgs mass corrections can be subtracted by a boundary condition of some ultraviolet complete theory, which is classically conformal, and only logarithmic divergences should be considered (see Ref. [6] for more detailed discussions). If this is the case, imposing the classically conformal symmetry to the theory is another way to solve the gauge hierarchy problem. Since there is no dimensionful parameter in this class of models, the classically conformal symmetry must be broken by quantum corrections. This structure fits the model first proposed by Coleman and Weinberg [40], where a model is defined as a massless theory and the classically conformal symmetry is radiatively broken by the Coleman–Weinberg (CW) mechanism, generating a mass scale through the dimensional transmutation.

\textsuperscript{1} In Ref. [38], the upper bound on the mass of the lightest additional scalar boson is obtained as $\approx 543$ GeV, which is independent of its isospin and hypercharge. Thus, the classically conformal model is strongly constrained without gauge extension.
In this paper we propose a classically conformal $U(1)_{B-L}$ extended SM with two Higgs doublets. An SM singlet, $B - L$ Higgs field develops its vacuum expectation value (VEV) by the CW mechanism, and the $U(1)_{B-L}$ symmetry is radiatively broken. This gauge symmetry breaking also generates the mass terms for the two Higgs doublets through quartic couplings between the two Higgs doublets and the $B - L$ Higgs field. We assume the quartic couplings to be all positive at the $U(1)_{B-L}$ breaking scale but, nevertheless, the electroweak symmetry breaking is triggered through the so-called bosonic seesaw mechanism [41–43], which is analogous to the seesaw mechanism for the neutrino mass generation and leads to a negative mass squared for the SM-like Higgs doublet. Because a negative quartic coupling may cause vacuum instability, it is important to take all quartic couplings to be positive, while in the conventional models, e.g., Refs. [3] and [29], the mixing coupling between the $SU(2)_L$ doublet and singlet fields is necessarily negative to realize the negative mass term of the SM-like Higgs doublet. Our model guarantees that the mixing couplings are positive at the breaking scale with a hierarchy among the quartic couplings, which successfully derives the bosonic seesaw mechanism. The hierarchy seems to be unnatural, but we find that the renormalization group evolutions of the quartic couplings dramatically reduce the large hierarchy toward high energies. On the other hand, a large hierarchy exists even in the conventional model, that is, the mixing coupling should be much small as (EW scale) $^2/v^2$ with a conformal symmetry breaking scale $v$, except for $v \sim O(1)$ TeV. Note that the degree of the hierarchy in our model does not increase as the symmetry breaking scale becomes larger.

In the following, let us explain our model in detail. We consider an extension of the SM with an additional $U(1)_{B-L}$ gauge symmetry. Our model has three scalar fields, that is, two Higgs doublets ($H_1$ and $H_2$) and one SM singlet, $B - L$ Higgs field ($\Phi$) are introduced. The $U(1)_{B-L}$ charges of $H_1$, $H_2$, and $\Phi$ are 0, 4, and 2, respectively. As is well known, the introduction of the three right-handed neutrinos ($N^i$, $i = 1, 2, 3$) with a $U(1)_{B-L}$ charge is crucial to make the model free from all the gauge and gravitational anomalies. In addition, we impose a classically conformal symmetry to the model, under which the scalar potential is given by

$$V = \lambda_1 |H_1|^4 + \lambda_2 |H_2|^4 + \lambda_3 |H_1|^2 |H_2|^2 + \lambda_4 (|H_1|^2 H_1 H_1 H_2 + |\Phi|^4 + \lambda_{H_1 \Phi} |H_1|^2 |\Phi|^2 + \lambda_{H_2 \Phi} |H_2|^2 |\Phi|^2 + (\lambda_{\text{mix}} |H_1|^2 |\Phi|^2 + h.c.).$$

(1)

Here, all of the dimensionful parameters are prohibited by the classically conformal symmetry. In this system, the $U(1)_{B-L}$ symmetry must be radiatively broken by quantum effects, i.e., the CW mechanism. The CW potential for $\Phi$ is described as

$$V_\Phi(\phi) = \frac{1}{4} \lambda_\Phi (v_\Phi)^4 + \frac{1}{8} \beta_{\lambda_\Phi} (v_\Phi)^4 \ln \left( v_\Phi^2 - \frac{25}{6} \right),$$

(2)

where $\beta_{\lambda_\Phi} = \phi^/\sqrt{2}$, and $v_\Phi = (\phi)$ is the VEV of $\Phi$. When the beta function $\beta_{\lambda_\Phi}$ is dominated by the $U(1)_{B-L}$ gauge coupling ($g_{B-L}$) and the Majorana Yukawa couplings of right-handed neutrinos ($Y_M$), the minimization condition of $V_\Phi$ approximately leads to

$$\lambda_\Phi \simeq \frac{11}{6 \pi^2} g_{B-L}^4 \left( 6 g_{B-L}^4 - \text{tr} Y_M^2 \right).$$

(3)

where all parameters are evaluated at $v_\Phi$. Through the $U(1)_{B-L}$ symmetry breaking, the mass terms of the two Higgs doublets arise from the mixing terms between $H_{1,2}$ and $\Phi$, and the scalar mass squared matrix is read as

$$-\mathcal{L} = \frac{1}{2} (H_1, H_2) \begin{pmatrix} \lambda_{H_1 \Phi} v_\Phi^2 & \lambda_{\text{mix}} v_\Phi^2 \\ \lambda_{\text{mix}} v_\Phi^2 & \lambda_{H_2 \Phi} v_\Phi^2 \end{pmatrix} (H_2) \begin{pmatrix} H_1 \end{pmatrix} \approx \frac{1}{2} (H_1', H_2') \begin{pmatrix} \lambda_{H_1 \Phi} v_\Phi^2 & \frac{\lambda_{\text{mix}} v_\Phi^2}{\lambda_{H_2 \Phi}} \\ \frac{\lambda_{\text{mix}} v_\Phi^2}{\lambda_{H_2 \Phi}} & 0 \end{pmatrix} (H_2')^\dagger.$$
where we have used $\text{tr}Y_M = N_vy_M$, for simplicity, and $N_v$ stands for the number of relevant Majorana couplings. In the following analysis, we will take $N_v = 1$ for simplicity, because our final results are almost insensitive to $N_v$. In the last equality in Eq. (11), we have used Eq. (3).

Before presenting our numerical results, we first discuss constraints on the model parameters from the perturbativity and the stability of the electroweak vacuum in the renormalization group evolutions. In our analysis, all values of couplings are given at $\mu = v_\Phi$. For $v_\Phi$ at the TeV scale, we find the constraint $g_{B-L} \lesssim 0.3$ to avoid the Landau pole of the gauge coupling below the Planck scale, while a more severe constraint $g_{B-L} \lesssim 0.2$ is obtained to avoid a blowup of the quartic coupling $\lambda_2$ below the Planck scale. From $g_{B-L} \lesssim 0.2$ and the experimental bound $M_{Z'} > 2.9$ TeV on the $Z'$ boson mass [44,45], we find $v_\Phi > 7.25$ TeV. The electroweak vacuum stability, in other words, $\lambda_3(\mu) > 0$ for any scales between the electroweak scale and the Planck scale, can be realized by sufficiently large $\lambda_3$ and/or $\lambda_4$ as $\lambda_3 = \lambda_4 \gtrsim 0.15$. To keep their perturbativity below the Planck scale, $\lambda_3 = \lambda_4 \lesssim 0.48$ must be satisfied, while we will find that the naturalness of the electroweak scale leads to a more severe upper bound.

To realize the hierarchy $\lambda_{H1\Phi} \ll \lambda_{mix} \ll \lambda_{H2\Phi}$, we take $\lambda_{H1\Phi} = 0$, for simplicity. When we consider $\lambda_{mix}$ in the range of $0 < \lambda_{mix} < 0.1 \times \lambda_{H2\Phi}$, the relation between $v_\Phi$ and $\lambda_{H2\Phi}$ obtained by Eq. (5) is almost uniquely determined. When we fix $\lambda_3 = \lambda_4 = 0.15$ as an example, we find $1$ TeV $\lesssim \lambda_{H2\Phi} v_\Phi^4 \lesssim 1.7$ TeV for $v_\Phi \gtrsim 10$ TeV, which is almost independent of $v_\Phi$. Since all heavy Higgs boson masses are approximately determined by $\lambda_{H2\Phi} v_\Phi^4$, they lie in the range between 1 TeV and 17 TeV. Such heavy Higgs bosons can be tested at the LHC in the near future.

In Eq. (5), it may be natural for the first term from the tree-level couplings dominates over the second term from the 1-loop correction. This naturalness leads to the constraint of $\lambda_3 = \lambda_4 < 0.26$, which is more severe than the perturbativity bound $\lambda_3 = \lambda_4 \lesssim 0.48$ discussed above. This condition is equivalent to the fact that the origin of the negative mass term mainly comes from the diagonalization of the scalar mass squared matrix in Eq. (4), namely, the bosonic seesaw mechanism.

Now we present the results of our numerical analysis. In Fig. 1, we show the renormalization group evolutions of the quartic couplings. Here, we have taken $\lambda_{H1\Phi} = 0$, and $\lambda_{H2\Phi} = 10^{-2}$ and $10^{-4}$ for $v_\Phi = 10$ TeV (solid lines) and 100 TeV (dashed lines), respectively. The red, green, and blue lines correspond to the running of $\lambda_{H1\Phi}$, $\lambda_{H2\Phi}$ and $\lambda_{mix}$, respectively. The rightmost vertical line denotes the reduced Planck scale $M_{Pl} = 2.4 \times 10^{18}$ GeV. In this plot, the other input parameters have been set as $g_{B-L} = 0.17$ and $\lambda_2 = \lambda_3 = 0.17$ to realize the electroweak vacuum stability without the Landau pole, and $\lambda_\Phi = 10^{-3}$. The value of $\lambda_1 = \lambda_2 = \lambda_4$ at $\mu = v_\Phi$ has been evaluated by extrapolating the SM Higgs quartic coupling with $M_H = 125$ GeV from the electroweak scale to $v_\Phi$. For this parameter choice, the $Z'$ boson and the right-handed neutrinos have the masses of the same order of magnitude as $M_{Z'} = 3.4$ (34) TeV and $M_N = 2.0$ (20) TeV for $v_\Phi = 10$ (100) TeV, while the $B-L$ Higgs boson mass is calculated as $M_{\Phi} = 0.23$ (2.3) TeV. As is well-known, $M_{\Phi} \lesssim M_{Z'}$ is a typical prediction of the CW mechanism. The masses of the heavy Higgs bosons are roughly 1 TeV for both $v_\Phi = 10$ TeV and 100 TeV.

In order for the bosonic seesaw mechanism to work, we have assumed the hierarchy among the quartic couplings as $\lambda_{H1\Phi} \ll \lambda_{mix} \ll \lambda_{H2\Phi}$ at the scale $\mu = v_\Phi$. One may think it unnatural to introduce this large hierarchy by hand. However, we find from Fig. 1 that the large hierarchy between $\lambda_{H1\Phi}$ and $\lambda_{H2\Phi}$ tends to disappear toward high energies. This is because the beta functions of the small couplings $\beta_{H1\Phi}$ and $\beta_{H2\Phi}$ are not simply proportional to themselves, but include terms given by other sizable couplings, such as $\beta_{H1\Phi}$ and $g_{B-L}^4$. This behavior of reducing the large hierarchy in the renormalization group evolutions is independent of the choice of the boundary conditions for $g_{B-L}$, $\lambda_3$, $\lambda_4$ and $\lambda_\Phi$. Therefore, Fig. 1 indicates that once our model is defined at some high energy, say, the Planck scale, the large hierarchy among the quartic couplings, which is crucial for the bosonic seesaw mechanism to work, is naturally achieved from a mild hierarchy at the high energy.

We see in Fig. 1 that $\lambda_{mix}$ is almost unchanged. This is because $\beta_{mix}$ is proportional to $\lambda_{mix}$, which is very small. Hence, the hierarchy between $\lambda_{mix}$ and the other couplings gets enlarged at high energies. To avoid this situation and make our model more natural, one may introduce additional vector-like fermions listed in Table 1, for example. (As another possibility, one may think that some symmetry forbids the $\lambda_{mix}$ term and it is generated via a small breaking.) Although $x$ is an arbitrary real number, we assume $x \neq 1$ to distinguish the new fermions from the SM leptons. These fermions have Yukawa couplings as

$$-\mathcal{L}_Y = Y_{SS} S \overline{S} \Phi S_R + Y_{SD} S \overline{D} \Phi D_R^I + Y_{DD} \overline{D} L \Phi D_R^I + Y_{DS} \overline{D} L H_1 S_R + Y_{SS} \overline{S} \Phi S_L + Y_{SS} \overline{S} \Phi S_L' + Y_{SS} \overline{S} \Phi S_L'' + Y_{SD} \overline{D} L \Phi D_L',$$

(12)

so that $\beta_{mix}$ includes terms of $Y_{SS} Y_{SD} Y_{DD} Y_{DS}$ and $Y_{SS} Y_{SD} \times Y_{DD} Y_{DS}'$, which are not proportional to $\lambda_{mix}$. Accordingly, the minimization condition of $V_\Phi$ is modified to

$$\lambda_\Phi \simeq \frac{11}{6 \pi^2} \left[ - \frac{1}{8} \left( Y_{SS}^2 + Y_{SS}'^2 \right) + \frac{3}{2} \left( 2Y_{SD}^2 + 2Y_{DD}^2 \right) \right].$$

(13)

From the conditions $\lambda_\Phi > 0$ and $g_{B-L} < 0.2$, the additional Yukawa contribution should satisfy $Y_{SS}^2 + Y_{SS}'^2 + 2Y_{SD}^2 + 2Y_{DD}^2 + 2Y_{DS}^2 < 3 \times (0.4)^4$. Note that the vector-like fermions masses are dominantly generated by $v_\Phi$, and they are sufficiently heavy to avoid the current experimental bounds.

Table 1

| Additional vector-like fermions. $x$ is a real number. |
|-----------------|-----------------|-----------------|
| $S_{L,R}$       | $(1, 1, 0)$     | $x$             |
| $S'_{L,R}$      | $(1, 1, 0)$     | $x - 2$         |
| $D_{L,R}$       | $(1, 2, 1/2)$   | $x$             |
| $D'_{L,R}$      | $(1, 2, 1/2)$   | $x + 2$         |
Fig. 2 shows the runnings of the quartic couplings for $v_\phi = 100$ TeV with the additional vector-like fermions. The input parameters are the same as before, while we have taken the Yukawa couplings as $Y_{SS} = Y_{SD} = Y_{DS} = 0.2$ and $Y_{SS} = Y_{SD} = Y_{DS} = 0.1$ at $\mu = v_\phi$, for simplicity. Toward high energies, $|\lambda_{\text{mix}}|$ becomes larger, and the hierarchy with the other couplings becomes mild. We can see that $\lambda_{\text{H1}\Phi}$ is negative below $\mu \approx 10^6$ GeV, because the contributions of additional Yukawa couplings to $\beta_{\lambda_{\text{H1}\Phi}}$ are effective below $\mu \approx 10^6$ GeV. Above the scale, the contribution of $U(1)_{B-L}$ couplings becomes effective, and then $\lambda_{\text{H1}\Phi}$ becomes positive. As a result, the large hierarchy at the $U(1)_{B-L}$ symmetry breaking scale can be realized with a mild hierarchy at some high energy. We expect that a ultraviolet complete theory, which provides the origin of the classical conformal invariance, takes place at the high energy.
