Tumor cells without mitochondrial (mt) DNA (ρ⁰ cells) are auxotrophic for uridine, and their growth is supported by pyruvate. While ATP synthesis in ρ⁰ cells relies on glycolysis, they fail to form tumors unless they acquire mitochondria from stromal cells. Mitochondrial acquisition restores respiration that is essential for de novo pyrimidine biosynthesis and for mitochondrial ATP production. The physiological processes that underpin intercellular mitochondrial transfer to tumor cells lacking mtDNA and the metabolic remodeling and restored tumorigenic properties of cells that acquire mitochondria are not well understood. Here, we investigated the changes in mitochondrial and nuclear gene expression that accompany mtDNA deletion and acquisition in metastatic murine 4T1 breast cancer cells. Loss of mitochondrial gene expression in 4T1 ρ⁰ cells was restored in cells recovered from subcutaneous tumors that grew from 4T1 ρ⁰ cells following acquisition of mtDNA from host cells. In contrast, the expression of most nuclear genes that encode respiratory complex subunits and mitochondrial ribosomal subunits was not greatly affected by loss of mtDNA, indicating ineffective mitochondria-to-nucleus communication systems for these nuclear genes. Further, analysis of nuclear genes whose expression was compromised in 4T1 ρ⁰ cells showed that immune- and stress-related genes were the most highly differentially expressed, representing over 70% of those with greater than 16-fold higher expression in 4T1 compared with 4T1 ρ⁰ cells. The monocyte recruiting chemokine, Ccl2, and Psmb8, a subunit of the immunoproteasome that generates MHCI-binding peptides, were the most highly differentially expressed. Early monocyte/macrophage recruitment into the tumor mass was compromised in 4T1 ρ⁰ cells but recovered before mtDNA could be detected. Taken together, our results show that mitochondrial acquisition by tumor cells without mtDNA results in bioenergetic remodeling and re-expression of genes involved in immune function and stress adaptation.

Keywords: mitochondrial DNA, gene expression, breast cancer, 4T1 model, tumor macrophages
INTRODUCTION

Intercellular mitochondrial transfer is a recently discovered phenomenon that has been shown to occur both in vitro (Spees et al., 2006; Berridge et al., 2016) and in vivo (Islam et al., 2012; Ahmad et al., 2014; Tan et al., 2015; Hayakawa et al., 2016; Osswald et al., 2016; Dong et al., 2017; Marlein et al., 2017, 2019). Respiration-deficient tumor cell lines without mitochondrial (mt) DNA (ρ⁰ cells), obtained by long-term exposure to low-dose ethidium bromide (King and Attardi, 1989), were shown to acquire mtDNA through intercellular mitochondrial transfer following co-culture with respiration-competent donor cells (Spees et al., 2006). Mitochondrial acquisition from stromal cells by metastatic breast cancer (4T1) and melanoma (B16) ρ⁰ cells injected into syngeneic mice was also observed with complete restoration of respiration and tumorigenicity (Tan et al., 2015; Dong et al., 2017).

Cells without mtDNA lack key subunits of mitochondrial respiratory chain complexes I, III, and IV, as well as two structural subunits of complex V that facilitate ATP synthase activity. They have no mitochondrial electron transport, cannot generate ATP through oxidative phosphorylation (OXPHOS), and rely exclusively on glycolysis for ATP production. Nevertheless, they maintain the mitochondrial membrane potential required for protein import into the mitochondria via the adenine nucleotide carrier and ATPase activity of sub-complex V (Appleby et al., 1999). Cells lacking mtDNA are auxotrophic for uridine, and most require additional pyruvate in vitro, a substrate for lactate dehydrogenase that re-oxidizes NADH produced during glycolysis and in the TCA cycle (Larm et al., 1994). In respiration-competent cells, most NADH is oxidized during mitochondrial respiration (see Herst et al., 2018b). However, uridine is essential because de novo pyrimidine biosynthesis is compromised in non-respiring ρ⁰ cells. These cells are unable to re-oxidize ubiquinol to ubiquinone, an essential electron acceptor not only for respiratory complexes I and II but also for dihydroorotate dehydrogenase (DHODH). Located at the outer surface of the inner mitochondrial membrane, DHODH catalyzes the fourth step in the de novo pyrimidine biosynthetic pathway (Evans and Guy, 2004). The importance of DHODH activity for tumor formation was shown by the inability of 4T1 breast carcinoma and B16 melanoma cells lacking the Dhodh gene to form tumors, with restoration of tumor formation after re-expression of the gene (Bajzikova et al., 2019).

When ρ⁰ tumor cells are injected into mice, they are immediately deprived of uridine. In order to form tumors, these cells acquire mitochondria from donor cells in the host to restore respiration and DHODH activity, allowing them to synthesize nucleic acids and divide. Although cells capable of donating intact mitochondria have been identified in vitro (Berridge et al., 2015; Herst et al., 2018a; Berridge et al., 2020), the physiologically relevant donor cells in different tissues are not known, and the signaling mechanisms that mediate intercellular mitochondrial transfer remain unclear. To better understand the cellular and molecular processes involved in mitochondrial transfer between cells, we investigated transcriptional differences between 4T1 and 4T1ρ⁰ cells and cells derived from subcutaneous tumors that grew from 4T1ρ⁰ cells (4T1ρ⁰ SC) using unbiased MinION long-read cDNA sequencing.

Differential gene expression between human tumor cell lines with and without mtDNA has been investigated previously by serial analysis of gene expression (SAGE) and quantitative real-time PCR using human 143B osteosarcoma cells (Duborjal et al., 2002). A set of nine nuclear genes encoding mitochondrial OXPHOS complex subunits was shown to be unchanged in 143Bρ⁰ cells. In addition, microarray approaches with MBA-MB-435 breast carcinoma cells (Delsite et al., 2002), A459 lung adenocarcinoma cells (Magda et al., 2008), and 143B and A459 cells (Mineri et al., 2009) reported both up- and down-regulation of the expression of nuclear genes between cells with and without mtDNA. Changes involved a variety of cell properties including cell cycle regulation and growth, cell signaling, respiration, and energy metabolism.

We have recently investigated the relative expression of selected nuclear genes in 4T1, 4T1ρ⁰, and derived cell lines following mitochondrial acquisition (Tan et al., 2015) and B16, B16ρ⁰, and derived cell lines with acquired mitochondria (Dong et al., 2017) by quantitative PCR (qPCR). While the lower expression of nuclear-encoded Sdhα, b, and d and selected complex I, III, IV, and V genes of up to 70% relative to parental cells was observed in 4T1ρ⁰ cells and in 4T1ρ⁰ SC cells (Tan et al., 2015), similar effects were not observed in B16ρ⁰ cells or B16ρ⁰ SC cells (Dong et al., 2017), suggesting that these effects may be tumor specific. In another study, we investigated the gene expression in 4T1, 4T1ρ⁰, and derived cell lines isolated at different times following injection using an array of genes encoding proteins that are imported into the mitochondria (Bajzikova et al., 2019). Patterns of gene expression clustered around the level of respiration recovery.

Because the scope of these approaches was constrained and designed to address specific questions, we decided to investigate the gene expression in the syngeneic 4T1 breast cancer model using cell lines with and without mtDNA and following mitochondrial acquisition. The aim was to better understand the role of mtDNA in the physiological processes involved in intercellular mitochondrial transfer, respiration recovery, and subsequent metabolic remodeling. Here, we show that most nuclear genes encoding mitochondrial respiratory complex subunits and mitochondrial ribosomal proteins were not markedly affected by the absence of mtDNA. The most highly differentially expressed, not expressed or poorly expressed in 4T1ρ⁰ cells, were associated with immune responses and stress adaptation rather than metabolic remodeling.

MATERIALS AND METHODS

Cell Culture, Tumor Formation, and Establishment of Tumor-Derived Cells

Full details of cell culture, tumor formation, and establishment of tumor-derived cells can be found in previously published work (Tan et al., 2015). Briefly, 4T1 cells sourced from ATCC were grown in Nunc flasks in RPMI 1640 medium containing 10%
fetal bovine serum (Gibco), 2 mM GlutaMAX, and 100 U/mL penicillin and 100 µg/ml streptomycin at 37°C in a 5% CO₂ incubator. 4T1ρ₀ cells were supplemented with 1 mM pyruvate and 50 µg/ml uridine. All consumables were purchased from Thermo Fisher Scientific (New Zealand) unless stated otherwise. For the preparation of 4T1ρ₀ cells, parental tumor cell lines were cultured for 10–12 weeks in low-dose ethidium bromide (50–100 ng/ml) supplemented with 1 mM pyruvate and 50 µg/ml uridine, followed by transfer to medium lacking ethidium bromide. Loss of mtDNA was monitored by sensitivity to 2 µM FCCP, PCR analysis loss of mitochondrial Cytb gene, and by pyruvate/uridine auxotrophy.

4T1 and 4T1ρ₀ cells (10⁵) were injected subcutaneously into the right flank of female Balb/c mice. 4T1ρ₀ sublines were derived from primary subcutaneous tumors (4T1ρ₀ SC) and cultured in the presence of 60 µM 6-thioguanine (6-TG) for 7–10 days. The 6-TG-resistant tumor cells survived and grew in culture. Mitochondrial acquisition by 4T1ρ₀ SC cells was established using transmission electron microscopy (TEM) and sequencing (Tan et al., 2015), confirming the presence of the host’s mitochondrial-specific single nucleotide polymorphism at position 16076 in the D-Loop and polyA region in location 9821.

**MiniON cDNA Sequencing and Mapping**

RNA from 4T1 and 4T1ρ₀ cells was extracted (Qiagen RNeasy Mini Kit) and quantified using the NanoDrop One Spectrophotometer (Thermo Fisher Scientific). RNA (50 ng) was used for library preparation for Oxford Nanopore Technologies (ONT) long-read cDNA sequencing. Samples were processed according to the most up-to-date ONT cDNA rapid barcoding protocol at the time of sequencing (SQK-PCS108, SQK-PCB109 with SQK-PBK004). Briefly, this process involved reverse transcription of extracted RNA using a custom poly TVN primer that binds to polyA RNA sequences, second-strand synthesis using a custom strand-switch primer, followed by PCR to incorporate barcode rapid attachment primers, to which rapid adapters were bound. For sequencing, libraries were prepared with up to six cDNA samples and on nine R9.4.1 ONT flow cells.

**Data Analysis of MinION Reads**

The program LAST was used to identify ONT barcodes present in sequenced reads, followed by a customized program (Eccles, 2019), designed to use barcode assignments to demultiplex reads into files based on their incorporated barcodes. Demultiplexed reads were then mapped to the ONT strand-switch primer sequence in order to identify the direction of transcription. Reads were mapped to the mouse transcriptome using LAST, grouped by mapped transcript, and counted producing a table that was further processed using DESeq2 (Love et al., 2014) to determine the differential expression (log₂ fold change) between 4T1 and 4T1ρ₀ cell lines and between 4T1 and 4T1ρ₀ SC cells. Standard error of the mean (SEM) log₂ fold change was estimated as the square root of the mean squared standard error of each calculated log₂ fold change as reported by DESeq2. We used FDR-adjusted p values reported by DESeq2 (Benjamini and Hochberg, 1995) of 0.1 as a threshold for statistical significance. Genes were categorized as stress- or immune-related based on descriptions provided in GeneCards and validated using the protein–protein interaction network database, String.

**qPCR**

Primers specific for individual genes were designed using the NCBI–NIH primer designing tool Primer-BLAST. These were: Ccl2 (CAGGTCCCTGTCATGCTTCT and GAGTGGGG CGTTAACTGCTC), Psmib8 (ACTACAGTTTCTCCGCGCAA and TTGAAAGGCAGTGTTGTTGT), Suma3 (GATGGCT CGTGGTGACAGTT and ACCGGAACTCAGTGCCTC), Ccl5 (GTGCCCACTCAGAGATTT and CTTGCGGCT CCTTCAGGT), Gng1l (CGCAGGAAGTCAATGGTGACAGATA and CTGGGATCCCTTTACCAAGG), Serpinf1 (ACGACA CGCTTGGACCTCTG and TCAAGTCTGGGTACACGTC), Gstk1 (CGTGTATGGTCTGAGATGAAGAT and CAGAGTGGGCGTCGCC), and Cst6 (GGCAAGCCCTCTTACT ACTTCC and GTCCTTTCCGGACACTCTGTGCTT). Rplp0 (TAACC CTGAAGTGTGCACAT and GTACCAGATCTCAGACAC), and Ppia (ACGCCACTGTGCCTTCTTC and CTGCA AACAGTCTCGAGGA) were used as housekeeping genes.

RNA was isolated from 4T1, 4T1ρ₀, and 4T1ρ₀ SC cells using Quick-RNA Miniprep (Zymo Research, New Zealand), and cDNA was obtained with SuperScript IV Reverse Transcriptase (Thermo Fisher Scientific, New Zealand). qPCR was then performed on an ABI7300 thermocycler (QuantStudio) using SYBR Green Master Mix (Applied Biosystems) with 5 ng/µl cDNA per reaction on fast cycling mode.

**mtDNA Sequencing**

4T1 and 4T1ρ₀ cells at 10⁶ per animal were injected subcutaneously into the flank of Balb/c female mice. The animals were sacrificed, and the pre-tumor regions were removed on Days 1, 2, and 3. The tissues were dissociated and passed through a 40 µm filter into a single-cell suspension and grown in medium containing uridine, pyruvate, and 60 µM 6-TG to obtain pure cultures of 4T1 and 4T1ρ₀ SC cells. DNA was extracted using Qiagen Blood & Tissue Kit and quantified on NanoDrop One Spectrophotometer. For mtDNA sequencing, the forward primer (5’ TCA GTA CTT CTA GCA TCA GTG GT 3’) and reverse primer (5’ GCT AGG CAG AAT AGG AGT GAT G 3’) were used to amplify a 2.149 bp fragment located specifically in the mitochondrial genome. PCR products were analyzed by gel electrophoresis on a 2% agarose gel and sequenced using the Sanger method.

**Confocal Microscopy**

Tumor tissue was snap frozen; 10 µM sections were fixed in acetone, permeabilized, and non-specific staining blocked. For Day 1 tissue, macrophages were visualized by co-staining with Alexa Fluor 647 anti-mouse F4/80 (BioLegend), CellTrace Violet, and anti-mouse fibroblast activation protein-α (FAP) (Thermo Fisher Scientific). Images were captured via confocal microscopy (Olympus FV12000). For calculation of macrophage infiltration, cells were stained with α-F4/80 (macrophage/red) and CellTrace Violet (tumor cells/blue). Fiji software was used to calculate the % of red pixels (macrophages)/% of blue pixels (tumor cells). At least 50 images were taken for each tumor, and 4–5 tumors...
were analyzed for each time point. The % of red pixels/\% of blue pixels of each photograph per time point is shown in box plots. The boxes represent the interquartile range (25–75\%) with a line at the median and whiskers representing the minimum and maximum values.

**RESULTS**

To investigate the transcriptional changes that occur in cells without mtDNA and following mitochondrial acquisition, we used unbiased MinION long-read cDNA sequencing of transcripts from 4T1 cells, 4T1\(\rho^0\) cells, and a cell line derived on Day 28 from a subcutaneous tumor that grew from 4T1\(\rho^0\) cells (4T1\(\rho^0\) SC) (Tan et al., 2015). As shown diagrammatically in Figure 1a, the mitochondrial morphology of 4T1\(\rho^0\) cells was distorted with low density internal staining and extensive loss of cristae compared with parental 4T1 cells (see Tan et al., 2015). 4T1\(\rho^0\) SC cells showed partial recovery of parental mitochondrial internal structures.

**Effects of mtDNA Deletion and Acquisition on Mitochondrial Gene Expression**

The effects of mtDNA deletion and acquisition on forward (heavy chain, orange) and reverse (light chain, green) transcription of the circular mitochondrial genome of 4T1, 4T1\(\rho^0\), and 4T1\(\rho^0\) SC cells are shown in Figure 1b. We observed a small amount of multiplex spillover in nanopore cDNA sequencing runs (about 0.1\%), as evidenced by the presence of a very small number of mitochondrial reads associated with 4T1\(\rho^0\) barcodes when sequenced together with 4T1 containing mtDNA (Supplementary Figure 1). No mitochondrial transcripts were found when 4T1\(\rho^0\) cell lines were multiplexed and sequenced together without other cell lines (Figure 1b).

Complete loss of mitochondrial transcripts in 4T1\(\rho^0\) cells was restored in 4T1\(\rho^0\) SC cells with the pattern of gene expression being almost identical to that with 4T1 cells. The results also show that the expression of individual mitochondrial genes in 4T1 and 4T1\(\rho^0\) SC cells varies by more than two orders of magnitude, consistent with steady-state transcriptional control previously demonstrated for the human mitochondrial genome (Duborjal et al., 2002).

**Effects of mtDNA Deletion and Acquisition on the Expression of Nuclear Genes Not Involved in Mitochondrial OXPHOS Complexes or Mitochondrial Ribosome Formation**

To better understand the effects of mtDNA on nuclear gene expression, we compared the expression of nuclear genes not involved in OXPHOS complexes and mitochondrial ribosome formation between 4T1 and 4T1\(\rho^0\) cells. After adjusting for read variation between sequencing runs, differential gene expression was visualized in a modified Bland–Altman MA plot adjusting for high variance at low gene expression levels (Figure 3). First, we focused on genes whose expression was compromised in 4T1\(\rho^0\) cells.

**Differentially Expressed Nuclear Genes With Little or No Expression in 4T1\(\rho^0\) Cells**

The two most highly differentially expressed transcripts expressed in 4T1 cells but not 4T1\(\rho^0\) cells were the immune response-related genes, Ccl2 and Psmb8 (Figures 4A,B). In addition, another 8 immune-related genes were among the 21 most highly differentially expressed genes with little or no expression in 4T1\(\rho^0\) cells. Of these, Ccl5 and Psmb9 are closely functionally related to Ccl2 and Psmb8, respectively. Ccl2, Ccl5, and Cccl10 are associated with inflammatory immune responses involving monocyte/macrophage recruitment, whereas Psmb8 and Psmb9 are involved in phenotype switching of macrophages to facilitate a type 2 tumor-promoting cytokine environment (Chen et al., 2016). The expression of a selection of these genes was validated by qPCR in 4T1, 4T1\(\rho^0\), and 4T1\(\rho^0\) SC cells (Figure 4C). Differential expression of these genes between 4T1 and 4T1\(\rho^0\) cells was confirmed. While the expression of Ccl2, Psmb8, and Ccl5 recovered fully in 4T1\(\rho^0\) SC cells, Gng11 that is involved in the transcriptional upregulation of the Ccl5 pathway in macrophage recruitment (Noerholm et al., 2011) recovered only partially.
Another group of five highly differentially expressed genes in the top 21 whose expression was compromised in 4T1ρ₀ cells was stress-related genes (Figures 5A,B). Of these, Serpinf1 and Gstk1 were the most highly differentially expressed. Differential expression of these two stress-related genes and Cst6 was confirmed by qPCR (Figure 5C). Recovery of the expression of stress-related genes in 4T1ρ₀ SC cells was more variable than that of immune-related genes, and this variability was confirmed by qPCR with the genes tested.

While immune- and stress response-related genes were the five most highly differentially expressed (4T1 > 4T1ρ₀) and comprised 15 of the top 21 most differentially expressed genes in this group, six more genes showed at least 16-fold higher expression in 4T1 cells than in 4T1ρ₀ cells. These genes had diverse functions and were not easily grouped, and none were identified as genes that might be involved in metabolic remodeling (Supplementary Table 1).

All but 4 of the 21 most highly differentially expressed genes whose expression was compromised in 4T1ρ₀ cells (81%) had no reads indicating that the presence or absence of mtDNA in itself is a critical factor in the expression of this subset of nuclear genes. For those genes whose expression was fourfold higher in 4T1 cells than in 4T1ρ₀ cells, 29 of 40 genes (73%) showed undetectable reads in 4T1ρ₀ cells (Supplementary Table 1).

Differentially Expressed Nuclear Genes With Higher Expression in 4T1ρ₀ Than in 4T1 Cells
In the group of genes with more than fourfold higher expression in 4T1ρ₀ cells than in 4T1 cells, there were only two genes (Mal and Tnfaip2) that could be linked to immune responses and two genes (Prl2c2 and Prl2c3) involved in cellular responses to nutrient depletion. Surprisingly, genes involved in metabolic remodeling toward glycolysis were not part of this group (Supplementary Table 2).

Effects of mtDNA Deletion and Acquisition on Macrophage Recruitment Into Early 4T1ρ₀ Tumors
Lack of Ccl2, Ccl5, and Cxcl10 expression in 4T1ρ₀ cells posed the question of whether or not macrophage recruitment into 4T1ρ₀ tumors early in their development was compromised, and if so, whether or not this affected tumor formation. Initial studies using fluorescence confocal microscopy of cryo-sliced sections stained with anti-F4/80 for macrophages and CellTrace Violet for tumor cells showed a distinct lack of macrophage infiltration into developing tumors 24 h after injection with 4T1ρ₀ cells (Figure 6A). In contrast, macrophage recruitment into
FIGURE 2 | Effects of mtDNA deletion and acquisition on the expression of nuclear and mitochondrial genes encoding mitochondrial OXPHOS complexes and mitochondrial ribosomal subunits. (A) MinION long-read cDNA sequencing was used to determine the log_{2} fold change in the differential gene expression of OXPHOS subunits complexes I–V, comparing 4T1ρ⁰ cells without mtDNA (n = 3) with 4T1 parental cells (n = 4) (left panel of each graph) and 4T1ρ⁰ SC cells with acquired mitochondria (n = 5) and 4T1 cells (right panel of each graph). Blue: mitochondrial-encoded genes for CI (seven subunits), CIII (one subunit), CIV (three subunits), and CV (two subunits). Black: 72 nuclear genes encoding subunits of complexes. (B) log_{2} fold change of the differential gene expression of nuclear-encoded mitochondrial ribosomal subunits (left panel of each comparative graph) and mitochondrially encoded rRNA (right panel of each comparative graph).

developing 4T1 tumors was clearly evident at this time point (Figure 6B).

We next investigated whether or not the lack of macrophage infiltration was sustained and if this affected tumor progression. In order to quantify macrophage infiltration, we collected tumors on different days after injection (n = 4–5 per time point), cryo-sliced stained sections through the middle of the tumors, and recorded at least 50 images per tumor using confocal microscopy. Co-staining with anti-F4/80 (macrophage marker) and anti-FAP-α indicated that the majority of macrophages inside the tumor mass were likely of the tumor-permissive M2 phenotype (Figures 7a,b). FIJI (ImageJ) was used to calculate the space taken up by macrophages (% of red pixels) relative to that taken up by tumor cells (% of blue pixels). Macrophage recruitment into the tumor mass was calculated as the ratio of % of red pixels over the % of blue pixels. Figure 7c shows that by Day 3, macrophage recruitment into 4T1ρ⁰ SC tumors had caught up to that in 4T1 tumors.

In order to determine how soon after injection mitochondrial transfer had occurred in the tumors that grew from 4T1ρ⁰ cells, we amplified a 2,149 bp fragment located specifically in the mitochondrial genome using PCR and determined the presence of this fragment by gel electrophoresis (Figure 7d) in subcutaneous 4T1ρ⁰ tumors at different time points. Days 2 and 3 tumors did not contain detectable amounts of mtDNA, but the mtDNA fragment was present from Day 4 onward, reaching parental levels by Day 14.

DISCUSSION

The ability of tumor cell lines without mtDNA to acquire mitochondria from adjacent cells in the body following inoculation provides a unique opportunity to investigate the adaptive cellular processes involved in intercellular mitochondrial transfer. Mitochondrial transfer restores mitochondrial gene expression, respiration, and mitochondrial ATP production as well as the ability to form tumors (Tan et al., 2015; Dong et al., 2017). While previous investigations have shown relatively small changes in nuclear gene expression in human tumor cell lines with and without mtDNA (Delsite et al., 2002; Magda et al., 2008; Mineri et al., 2009),
analytical approaches have been limited to genes of interest or gene sets in commercial microarrays. The focus of these approaches has been on altered metabolic and signaling pathways in human tumor cell lines in culture that are associated with glycolytic adaptation. The use of a tumor cell model that acquires mitochondria in vivo has added a layer of potential utility to this approach. We have previously shown that in a murine metastatic melanoma cell line, the up-regulation of mtDNA gene expression is largely ineffective in the absence of nuclear communication (Grasso et al., 2017), results that are in line with our limited analysis of nuclear-encoded respiratory complex subunits in the 4T1 model (Tan et al., 2015). The effects of mtDNA deletion on nuclear-encoded respiratory complex subunits were more variable than the changes we observed in steady-state nuclear gene expression of these subunits. Differences between steady-state nuclear gene expression and protein subunit levels of respiratory complexes in p0 cells compared with parental tumor cells could be explained by post-translational mechanisms.

Expression analysis of nuclear genes not encoding mitochondrial OXPHOS complexes or mitochondrial ribosomal protein subunits showed that 15 of the 22 most highly expressed genes with greater than 16-fold expression in 4T1 cells compared with 4T1p0 cells could be linked to immune and stress responses. Of these, Ccl2, encoding a monocyte/macrophage-recruiting chemokine, and Psmmb8, encoding a subunit of the immunoproteasome that facilitates protein processing to generate MHCI-binding peptides, were the two most highly differentially expressed genes. Genes encoding Ccl5, another monocyte attracting chemokine, and Psmb9 that has similar function to Psmb8 were also differentially expressed as was the gene encoding the proinflammatory chemokine, Cxcl10, a C-X-C motif cytokine involved in the development of T cell effector function. Five other immune response genes, mostly involved in regulating inflammatory immune responses and antigen processing, were present in this group of highly differentially expressed genes, together representing 48% of the 21 most highly differentially expressed genes (4T1 > 4T1p0). The only gene in this group of immune response genes that has been previously identified as being differentially expressed between wild type and p0 tumor cells is Psmb8 (Magda et al., 2008), but in this case, it was more highly expressed in A549p0 cells than in A549 human lung adenocarcinoma cells.

Our results have confirmed that 4T1 cells express transcripts for the monocyte-recruiting chemokines Ccl2 (MCP-1) and Ccl5 (RANTES) as shown previously in 4T1 cells (Kurt et al., 2001; Vitiello et al., 2004; DuPré et al., 2007) and 4T1 cells isolated from 4T1 tumors (DuPré et al., 2007), with both chemokines present in conditioned media from 4T1 cells (Kurt et al., 2001; Vitiello et al., 2004; Cho et al., 2012; Kuan and Ziegler, 2018). Ccl2 in conditioned media from 4T1 cells was effective in amplifying macrophage-mediated innate inflammatory immune responses

FIGURE 3 | mtDNA deletion affects the expression of nuclear genes involved in immune- and stress-related functions. MA scatter plot showing log2 fold change and mean transcript expression of nuclear genes differentially expressed in 4T1 (n = 4) and 4T1p0 cells (n = 3). Nuclear genes encoding respiratory complex subunits and mitochondrial ribosomal subunits were excluded. Genes with an adjusted log2 fold change in p-value of ≤0.1 were expressed higher in 4T1 (top) and higher in 4T1p0 (bottom) in black, unless immune-related (green dots) or stress-related (red dots). Genes with a p-value of ≥0.1 are in gray.
FIGURE 4 | Expression of nuclear-encoded immune-related genes absent/low in cells deleted of mtDNA and restored/partially restored after cells acquire mitochondria. (A) Table of immune-related genes with log₂ fold change > 4, higher in 4T1 cells than in 4T1ρ₀ cells, and 4T1 cells than in 4T1ρ₀ SC cells that have acquired mitochondria. Standard error (SE) is based on average log₂ fold change and p-value adjusted to account for false discovery rate. Genes not expressed in 4T1ρ₀ (∗). Genes weakly expressed in 4T1ρ₀ (∗∗). (B) Bar graph of (A) showing log₂ fold change of immune-related genes higher in 4T1 cells than in 4T1ρ₀ and 4T1ρ₀ SC cells. (C) log₂ fold change in the expression of immune-related genes Ccl2, Pamb8, Sumo3, Ccl5, and Gng11 from table (A) validated by qPCR in 4T1, 4T1ρ₀, and 4T1ρ₀ SC cells. p-Values were determined from Ct values prior to log transformation and normalization; ∗∗∗∗p < 0.0001.

that included Ccl2 production in the presence and absence of the lipopolysaccharide (LPS) and migration (Cho et al., 2012; Madera et al., 2015), as well as phagocytosis (Madera et al., 2015).

Stress response-related genes were also well represented in the 21 most highly expressed genes in 4T1 cells compared with 4T1ρ₀ cells, with five genes in this group. Of particular interest is Serpinf1 (pigment epithelial-derived factor, PEDF), a member of the large serum proteinase inhibitor family that lacks proteinase activity and is a potent inhibitor of angiogenesis and adipogenesis via PPAR-γ (Gattu et al., 2013). Serpinf1 promotes inflammation; impairs glucose uptake, ATP production, and mitochondrial function; and compromises fatty acid oxidation, while increasing the expression of genes involved in fatty acid oxidation via PPAR-γ (Carnagarin et al., 2015). Other genes in this group include those encoding the glutathione-S-transferases, Gstk1 and Gstm1, the cysteine proteinase inhibitor, Gst6, and the cysteine-and glycine-rich protein-2, Csrp2, that is down-regulated in response to cell injury.

Notably, 12 of 15 (80%) of the most highly differentially expressed immune and stress response-related genes expressed in 4T1 cells recorded zero reads in 4T1ρ₀ cells. In this context, zero reads by MinION nanopore cDNA sequencing is a highly relevant result and a major point of difference between this 3rd generation sequencing platform as applied to gene expression
**FIGURE 5** | Expression of nuclear-encoded stress-related genes absent/low in cells without mtDNA and restored/partially restored after cells acquire mitochondria. (A) Table of stress-related genes with log₂ fold change > 4, higher in 4T1 cells than in 4T1 ρ₀ cells, and in 4T1 cells than in 4T1 ρ₀ SC cells that have acquired mitochondria. | Gene | Description | Function | 4T1 vs 4T1 ρ₀ | p-value adjusted | 4T1 vs 4T1 ρ₀ SC | p-value adjusted |
|------|-------------|----------|---------------|----------------|-----------------|-----------------|
| Serpinf1 | Serine Proteinase Inhibitor Family 1 | Induces PPAR-gamma that increases mt number, citrate synthase, complex I and antioxidant enzyme catalase | 7.7 ± 1.3 | 6.3E-08 | 5.7 ± 0.9 | 1.2E-09 |
| Gskt1 | Glutathione-S-transferase kappa 1 | Cellular detoxification | 7.4 ± 1.5 | 7.1E-06 | 1.1 ± 0.9 | 4.8E-02 |
| Gstm1 | Glutathione-S-transferase | Detoxification of electrophilic compounds | 5.7 ± 1.7 | 7.3E-04 | 0.2 ± 0.5 | 7.1E-01 |
| Cst6 ** | Cystatin-6 | Active cysteine protease inhibitors | 4.4 ± 1.0 | 2.3E-05 | 1.4 ± 0.8 | 1.2E-02 |
| Cerp2 * | Cysteine and glycine-rich protein 2 | Downregulated in response to cell injury | 4.1 ± 2.0 | 4.9E-03 | -0.3 ± 0.4 | 5.2E-01 |

* No expression in 4T1 ρ₀
** Low expression in 4T1 ρ₀

**FIGURE 6** | Macrophages are absent in the tumor bulk 24 h after subcutaneous injection with 4T1 ρ₀ cells. Representative confocal images of and 4T1 ρ₀ (A) and 4T1 (B) tumor tissues from Day 1 tumors stained with the macrophage antibody F4/80 (red) and CellTrace Violet (blue). n = 4–5.
analysis and other 2nd generation sequencing methodologies, all of which are insensitive to low expressing genes because of high background noise. Overall, 17 genes with log₂FC > 4 (16-fold) showed no transcripts in 4T1ρ₀ cells, whereas 29 of 40 genes with log₂FC ≥ 2.0 were not expressed. These results were unexpected and show the potential of MinION nanopore cDNA sequencing to identify highly significant differential expression of nuclear genes that are not expressed in ρ₀ cells and therefore require the presence of mtDNA for their expression.

We also showed that the expression of most of the immune and stress response genes whose expression was compromised in 4T1ρ₀ cells partially or fully recovered expression in 4T1ρ₀ SC cells that had acquired mitochondria, and this was confirmed by qRT-PCR analysis for a subset of these genes. A notable exception was Serpinf1 where little recovery of gene expression was observed, suggesting a more complex mechanism of regulatory control for this gene.

A role for mitochondrial respiration in regulating the expression of nuclear genes involved in tumor immune responses has not been described before. Depending on the activation status of immune cells, both anti-tumor (type 1) and tumor-supporting (type 2) responses have been documented. With respect to infiltration of immune cells into the early breast tumor microenvironment, macrophages are the main players, constituting up to 50% of the tumor mass in these tumors (Obeid et al., 2013). Macrophages readily switch between M1 anti-tumor and M2 tumor-supporting phenotypes (Obeid et al., 2013). With respect to tumor progression, tumor-associated macrophages (TAMs) have been associated with poor patient survival (Bingle et al., 2002). We show here that macrophage recruitment was extremely low in 4T1ρ₀ tumors 1 day after injection, but that recruitment normalized to parental levels by Day 3, and that the recruited cells were likely of the M2 phenotype (F4/80⁺ and FAP⁺, Figure 7b). Interestingly, mtDNA was present in Day 4 tumors and may have been present before that time point at levels below the detection limit of our methodology. Our in vitro work in co-cultures has shown that mitochondrial transfer occurs within 24 h of co-culture in a small percentage.
of cells (unpublished data). In addition to 4T1 cells, cancer-associated fibroblasts (CAFs) also release Ccl2 and Ccl5 to recruit monocytes/macrophages and re-polarize M1 macrophages to M2-like TAMs (Soria and Ben-Baruch, 2000; Owen et al., 2011; Biswas et al., 2014; Katanov et al., 2015; Madera et al., 2015; Cordova et al., 2017; Liubomirski et al., 2019). Thus, it is possible that increased macrophage recruitment by Day 3 may involve Ccl2 release by CAFs at a very early stage of tumor formation. We further found that a delay in macrophage recruitment did not affect tumor progression as the 4T1p<sup>B</sup> SC tumors remained very small until Day 21 when they became palpable and when the increase in tumor mass was obvious (Bajzikova et al., 2019).

Our results have shown that mitochondrial encoded gene expression was restored to normal levels after mitochondrial acquisition. Interestingly, the expression of most nuclear genes that encode subunits of mitochondrial respiratory complexes and mitochondrial ribosomal proteins was not markedly affected by loss of mtDNA. For other nuclear genes whose expression was affected, the expression was partially or fully restored following mitochondrial acquisition. We were unable to identify nuclear genes that might be involved in recruitment of cells known to act as mitochondrial donors (Spees et al., 2006; Herst et al., 2018a). However, we did identify lack of expression of immune-related genes involved in monocyte/macrophage recruitment and lack of recruitment of these cells into the 4T1p<sup>B</sup> cell mass on Day 1.

Although the mechanism(s) whereby the presence or absence of mtDNA affects the regulation of nuclear expression is unclear, our results lead us to conclude that mitochondrial acquisition by tumor cells without mtDNA results in bioenergetic remodeling and re-expression of genes involved in immune function and stress adaptation.

**DATA AVAILABILITY STATEMENT**

The datasets presented in this study can be found in online repositories. The names of the repository/repositories and accession number(s) can be found below: https://www.ebi.ac.uk/ena, https://www.ebi.ac.uk/ena/data/view/PRJEB35129, https://doi.org/10.5281/zenodo.1244087, https://doi.org/10.5281/zenodo.1244087, https://doi.org/10.17504/protocols.io.8azhsf6, and https://doi.org/10.17504/protocols.io.8azhsf6.

**ETHICS STATEMENT**

The animal study was reviewed and approved by the Victoria University of Wellington Animal Ethics Committee.

**AUTHOR CONTRIBUTIONS**

MB, PH, and DE designed the research. CG, DE, PH, M-SF, SB, and RD conducted the research. MB, PH, and CG wrote the manuscript. All authors contributed to manuscript revision.

**FUNDING**

This research was supported by the Health Research Council of New Zealand, the Cancer Society of New Zealand, the Malaghan Institute of Medical Research, the University of Otago, Wellington, and the Institute of Biotechnology, CAS (RVO: 86653026). SB was supported by an International Mobility Grant of the Institute of Biotechnology CAS (CZ.02.2.69/0.0/16_027/0008353) from the ESF and by Czech Science Foundation grant (20-11724Y).

**ACKNOWLEDGMENTS**

We thank summer student, Emily Schulpen, for her input into String gene association analysis and Olivier Lamiable for his helpful molecular advice.

**SUPPLEMENTARY MATERIAL**
