Abstract
In this note, we show that the family of Cayley graphs of a finitely generated subgroup of \( \text{GL}_{n_0}(\mathbb{F}_p(t)) \) modulo some admissible square-free polynomials is a family of expanders under certain algebraic conditions. Here is a more precise formulation of our main result. For a positive integer \( c_0 \), we say a square-free polynomial is \( c_0 \)-admissible if degree of irreducible factors of \( f \) are distinct integers with prime factors at least \( c_0 \). Suppose \( \Omega \) is a finite symmetric subset of \( \text{GL}_{n_0}(\mathbb{F}_p(t)) \), where \( p \) is a prime more than 5. Let \( \Gamma \) be the group generated by \( \Omega \). Suppose the Zariski-closure of \( \Gamma \) is connected, simply connected, and absolutely almost simple; further assume that the field generated by the traces of \( \text{Ad}(\Gamma) \) is \( \mathbb{F}_p(t) \). Then for some positive integer \( c_0 \) the family of Cayley graphs \( \text{Cay}(\pi_{f(t)}(\Gamma), \pi_{f(t)}(\Omega)) \) as \( f \) ranges in the set of \( c_0 \)-admissible polynomials is a family of expanders, where \( \pi_{f(t)} \) is the quotient map for the congruence modulo \( f(t) \).

1 | INTRODUCTION

1.1 | Statement of the main results

Let $\Gamma$ be a subgroup of a compact group $G$. Suppose $\Omega$ is a finite symmetric (that means $\omega \in \Omega$ implies $\omega^{-1} \in \Omega$) generating set of $\Gamma$. Suppose $\Gamma$ is the closure of $\Gamma$ in $G$ and $P_{\Omega}$ is the probability counting measure on $\Omega$. Let

$$T_{\Omega} : L^{2}(\Gamma) \rightarrow L^{2}(\Gamma), \quad T_{\Omega}(f) : = P_{\Omega} * f : = \frac{1}{|\Omega|} \sum_{\omega \in \Omega} L_{\omega}(f),$$

where $L_{\omega}(f)(g) : = f(\omega^{-1}g)$. Then it is well-known that $T_{\Omega}$ is a self-adjoint operator, $T_{\Omega}(1_{\Gamma}) = 1_{\Gamma}$, where $1_{\Gamma}$ is the constant function on $\Gamma$, and the operator norm $\|T_{\Omega}\|$ is 1. So, the spectrum of $T_{\Omega}$
is a subset of $[-1, 1]$ and $T_\Omega$ sends the space $L^2(\overline{\Gamma})^\circ$ orthogonal to the constant functions to itself. Let $T_\Omega^\circ$ be the restriction of $T_\Omega$ to $L^2(\overline{\Gamma})^\circ$. Let

$$\lambda(P_\Omega; G) := \sup\{|c| \mid c \text{ is in the spectrum of } T_\Omega^\circ\}. $$

If $\lambda(P_\Omega; G) < 1$, we say the left action $\Gamma \curvearrowright G$ of $\Gamma$ on $G$ has spectral gap.

It is worth mentioning that, if $\Omega_1$ and $\Omega_2$ are two generating sets of $\Gamma$ and $\lambda(P_\Omega; G) < 1$, then $\lambda(P_{\Omega_2}; G) < 1$. So, having spectral gap is a property of the action $\Gamma \curvearrowright G$, and it is independent of the choice of a generating set for $\Gamma$. The following is the main result of this article.

**Theorem 1.** Let $\Omega$ be a finite symmetric subset of $\text{GL}_{n_0}(\mathbb{F}_p[t, 1/r_0(t)])$ where $p > 5$ is prime and $r_0(t) \in \mathbb{F}_p[t] \setminus \{0\}$. Let $\Gamma$ be the group generated by $\Omega$. Suppose the Zariski-closure $G$ of $\Gamma$ in $\text{GL}_{n_0}(\mathbb{F}_p)$ is a connected, simply connected, absolutely almost simple group. Suppose the field generated by $\text{Tr}(\text{Ad}(\Gamma))$ is $\mathbb{F}_p(t)$. Then there is a positive integer $c_0$ such that

$$\sup_{\{\ell_i(t)\}_{i=1}^\infty \in I_{r_0,c_0}} \lambda\left(P_\Omega; \prod_{i=1}^\infty \text{GL}_{n_0}(\mathbb{F}_p[t]/\langle \ell_i(t) \rangle)\right) < 1,$$

where $\{\ell_i(t)\}_{i=1}^\infty \in I_{r_0,c_0}$ if and only if $\ell_i(t)$ are irreducible, $\ell_i(t) \nmid r_0(t)$, and $\{\deg \ell_i\}_{i=1}^\infty$ is a strictly increasing sequence consisting of integers more than 1 with no prime factors less than $c_0$.

It is well-known that Theorem 1 has immediate application in the explicit construction of expanders. Let us quickly recall that a family of $d$-regular graphs $X_i$ is called a family of expanders if the size $|V(X_i)|$ of the set of vertices goes to infinity and there is a positive number $\delta_0$ such that for any subset $B$ of $V(X_i)$ we have

$$\frac{|e(B, V(X_i) \setminus B)|}{\min(|B|, |V(X_i) \setminus B|)} > \delta_0,$$

where $e(B, C)$ is the set of edges that connect a vertex in $B$ to a vertex in $C$. Expanders have a lot of applications in theoretical computer science (see [22] for a survey on such applications).

Now we can give the equivalent formulation of Theorem 1 in terms of expander graphs (see [38, Remark 15] or [31, Section 4.3]).

**Theorem 1’.** Let $\Omega$ be a finite symmetric subset of $\text{GL}_{n_0}(\mathbb{F}_p[t, 1/r_0(t)])$ where $p > 5$ is prime and $r_0(t) \in \mathbb{F}_p[t] \setminus \{0\}$. Let $\Gamma$ be the subgroup generated by $\Omega$. Suppose the Zariski-closure $G$ of $\Gamma$ in $\text{GL}_{n_0}(\mathbb{F}_p)$ is a connected, simply connected, absolutely almost simple group. Suppose the field generated by $\text{Tr}(\text{Ad}(\Gamma))$ is $\mathbb{F}_p(t)$. Then there is a positive integer $c_0$ such that the family of Cayley graphs

$$\{\text{Cay}(\pi_{f(t)}(\Gamma), \pi_{f(t)}(\Omega)) \mid f(t) \in S_{r_0,c_0}\}$$

is a family of expanders where $S_{r_0,c_0}$ consists of square-free polynomials $f(t) \in \mathbb{F}_p[t]$ with prime factors $\ell_i(t)$ such that (1) $\ell_i(t) \nmid r_0(t)$, (2) $\deg \ell_i > 1$, (3) $\deg \ell_i \neq \deg \ell_j$ if $i \neq j$, and (4) $\deg \ell_i$ does not have a prime factor less than $c_0$ and $\pi_{f(t)}$ is induced by the quotient map $\pi_{f(t)} : \mathbb{F}_p[t, 1/r_0(t)] \to \mathbb{F}_p[t]/\langle f(t) \rangle$. 

1.2 What super-approximation is and an ultimate speculation

To put Theorem 1 in the perspective of previous works, let us say what super-approximation is in a very general setting.

**Definition 2.** Suppose $A$ is an integral domain, and $\Omega$ is a finite symmetric subset of $\text{GL}_{n_0}(A)$. Let $\Gamma$ be the group generated by $\Omega$. Suppose $C$ is a family of finite index ideals of $A$. We say $\Gamma$ has super-approximation with respect to $C$ if $\sup_{a \in C} \lambda(\pi_a[P_{\Omega}]; \text{GL}_{n_0}(A/a)) < 1$, where $\pi_a$ is the group homomorphism induced by the quotient map $A \to A/a$ and $\pi_a[P_{\Omega}]$ is the push-forward of $P_{\Omega}$ under $\pi_a$. We simply say $\Gamma$ has super-approximation if it has super-approximation with respect to the set of all the finite index ideals of $A$.

Because of several groundbreaking results in the past decade (see [2–6, 9, 19, 20, 37–41, 48]), we have a very good understanding of super-approximation property for finitely generated subgroups of linear groups over $A := \mathbb{Z}[1/q_0]$ (a finitely generated subring of $\mathbb{Q}$). In this case, it is proved that $\Gamma$ has super-approximation with respect to fixed powers of square-free ideals [39, 41] and powers of prime ideals [38, 39] if and only if the connected component $G^0$ of the Zariski-closure of $\Gamma$ in $(\text{GL}_{n_0})_\mathbb{Q}$ has trivial abelianization. Based on these results, we have the following conjecture.

**Conjecture 3 (Super-approximation conjecture over $\mathbb{Q}$).** Suppose $\Omega$ is a finite symmetric subset of $\text{GL}_{n_0}(\mathbb{Z}[1/q_0])$, $\Gamma = \langle \Omega \rangle$, and $G^0$ is the connected component of the Zariski-closure of $\Gamma$ in $(\text{GL}_{n_0})_\mathbb{Q}$. Then $\Gamma$ has super-approximation if and only if $G^0$ has trivial abelianization.

In the beautiful survey by Lubotzky [32], he goes further and make an analogues conjecture (see [32, Conjecture 2.25]) for an arbitrary finitely generated integral domain $A$. Note that such a conjecture implies that super-approximation is a Zariski-topological property; that means if two groups have equal Zariski-closures, then either both of them have super-approximation or neither have this property. It turns out that this conjecture is false in this generality (see [41, Example 5]); there are two finitely generated subgroups of $\text{GL}_{n_0}(\mathbb{Z}[1])$ such that (1) they have equal Zariski-closures in $(\text{GL}_{n_0})_\mathbb{Q}[1]$, and (2) one of them has super-approximation and the other one does not. This shows that for an arbitrary integral domain $A$ one needs a refiner understanding of $\Gamma$ to determine if it has super-approximation. The key point is that super-approximation is about how well $\Gamma$ is distributed in its closure $\overline{\Gamma}$ in the compact group $\text{GL}_{n_0}(\widehat{A})$ where $\widehat{A} := \lim_{\leftarrow \left| A/a \right| < \infty} A/a$ is the profinite closure of the ring $A$. When the field of fractions $Q(A)$ has a subfield $F$ such that $[Q(A) : F] < \infty$, $\Gamma$ might satisfy some hidden polynomial relations over $F$ which disappear over $Q(A)$. Of course such polynomial relations are still satisfied in $\overline{\Gamma}$; and so these are vital in understanding the group structure of $\overline{\Gamma}$. To detect the mentioned hidden polynomial relations, one has to use Weil’s restriction of scalars and view $\text{GL}_{n_0}(Q(A))$ as the $F$-points of $R_{Q(A)/F}(\text{GL}_{n_0})_Q(A)$. More or less what we are hoping for is to have a finitely generated ring $A_0$ and a group scheme $G_0$ over $A_0$ such that $\overline{\Gamma}$ can be realized as an open subgroup of $G_0(\widehat{A_0})$ where $\widehat{A_0}$ is the profinite closure of $A_0$. Strong approximation (see [33, 35, 36, 49]) gives us such a result under various extra algebraic conditions. This is partially responsible for some of the extra technical conditions in Theorem 1 compared to the mentioned results over $\mathbb{Z}[1/q_0]$; it will be explained later why we need some additional technical conditions.

In light of this discussion, it makes sense to formulate a conjecture for super-approximation property of a finitely generated subgroup $\Gamma$ of $\text{GL}_{n_0}(A)$ based on group theoretic properties of its
closure $\Gamma$ in $\text{GL}_{n_0}(\hat{A})$. As Lubotzky says in his survey [32, Conjecture 2.25], this conjecture is quite a fantasy at this point.

**Conjecture 4** (Super-approximation conjecture for a finitely generated integral domain). Suppose $A$ is a finitely generated integral domain, $\Omega$ is a finite symmetric subset of $\text{GL}_{n_0}(A)$, and $\Gamma$ is the subgroup generated by $\Omega$. Let $\hat{A} := \lim_{\leftarrow} A / \mathfrak{a}$ be the profinite closure of $A$ and $\overline{\Gamma}$ is the closure of $\Gamma$ in $\text{GL}_{n_0}(\hat{A})$. Then $\Gamma$ has super-approximation if and only if any open subgroup $\Lambda$ of $\overline{\Gamma}$ has finite abelianization; that means $|\Lambda/[\Lambda,\Lambda]| < \infty$.

Let us make two remarks: (1) since $A$ is a finitely generated ring, for any maximal ideal $\mathfrak{m}$ we have that $A/\mathfrak{m}$ is a finitely generated ring and a field; and so $|A/\mathfrak{m}| < \infty$ if $\mathfrak{m}$ is a maximal ideal. Moreover, since $A$ is a finitely generated integral domain, it is a Jacobson ring which means intersection of its maximal ideals is zero. Hence, $A$ can be (naturally) embedded into $\hat{A}$. Therefore, it does make sense to talk about the closure of $\Gamma$ in $\text{GL}_{n_0}(\hat{A})$. (2) Using the argument given in [39, Proposition 8], one can get the ‘only if’ part of Conjecture 4. It is worth mentioning that super-approximation (also known as superstrong approximation) has been found to be extremely instrumental in a wide range of problems; see [10] for a collection of its applications.

### 1.3 Best related result prior to this work

The best known result on super-approximation for linear groups over a global function field, prior to this work, is due to Bradford [7]. In [7], under the extra assumption that the degree $\deg \ell_i$ of irreducible factors $\ell_i$ are prime, a version of Theorem 1′ for subgroups of $\text{SL}_2(F_p[t])$ is proved. Bradford also highlights many of the subtleties involved in the positive characteristic case.

### 1.4 Notation

Throughout this paper for any group $G$ and a subgroup $H$, $Z(G)$ is the center of $G$, $C_G(H)$ is the centralizer of $H$ in $G$, and $N_G(H)$ is the normalizer of $H$ in $G$ as usual. If $G$ and $H$ are algebraic groups, then these notions are considered in the category of algebraic groups.

For a finite subset $S$ of a group $G$, we denote by $P_S$ the uniform probability measure supported on $S$; that means

$$P_S(A) = |A \cap S|/|S|$$

for any $A \subseteq G$.

For any measure $\mu$ with finite support on $G$ and $g \in G$, we let $\mu(g) := \mu(\{g\})$.

For any two measures with finite support $\mu, \nu$ on $G$, the convolution of $\mu$ and $\nu$ is denoted by $\mu \ast \nu$; and so

$$(\mu \ast \nu)(g) = \sum_{h \in G} \mu(h)\nu(h^{-1}g).$$

The $l$-fold convolution of $\mu$ with itself is denoted by $\mu^{(l)}$, and $\tilde{\mu}$ denotes the measure such that $\tilde{\mu}(g) = \mu(g^{-1})$. 

For a measure $\mu$ with finite support on a group $G$ and a group homomorphism $\pi : G \to H$, we denote by $\pi[\mu]$ the push-forward of $\mu$ under $\pi$; that means $\pi[\mu](\overline{A}) := \mu(\pi^{-1}(\overline{A}))$ for any subset $\overline{A}$ of $H$.

For subsets $A, A_1, \ldots, A_n$ of a group $G$, we write

$$\prod_{i=1}^n A_i := \{a_1 a_2 \ldots a_n | a_i \in A_i\}$$

for the product set of $A_1, \ldots, A_n$ and we write

$$\prod_{i=1}^k A_i := \{a_1 a_2 \ldots a_k | a_i \in A, \ 1 \leq i \leq k\}$$

for the set consisting of products of $k$ elements of $A$. We denote by $\bigoplus_{i=1}^k G_i$, the direct sum of the groups $G_1, \ldots, G_k$.

We use Vinogradov’s notation $x \ll_A y$ to mean $|x| < C y$ for some positive constant $C$ depending on the parameter $A$. For any constant $\delta$, $K = \Theta_A(\delta)$ means $\delta \ll_A K \ll_A \delta$. The subscript will be omitted from the above notation if either the constant is universal, or if the dependencies are clear from context.

For any positive integer $n$, $[1..n]$ denotes the set of integers that are at least 1 and at most $n$.

We use $\text{pr}_i : \bigoplus_{j \in J} G_j \to G_i$ to denote the projection to the $i$th factor. For $J \subseteq I$, we identify the group $\bigoplus_{i \in J} G_i$ with its natural inclusion in $\bigoplus_{i \in I} G_i$.

For any prime $p$, we let $\overline{\mathbb{F}}_p$ be an algebraic closure of a finite field $\mathbb{F}_p$ of order $p$. For any prime $p$ and positive integer $n$, $\mathbb{F}_p^n$ denotes the unique finite subfield of $\overline{\mathbb{F}}_p$ that has order $p^n$.

For a field $F$, we let $F^\times := F \setminus \{0\}$. For $f(t) \in \mathbb{F}_q[t] \setminus \{0\}$, we let $N(f) := |\mathbb{F}_q[t]/(f(t))|$. For an irreducible polynomial $\ell(t) \in \mathbb{F}_q[t]$ we let $v_\ell : F_q[t] \to \mathbb{Z} \cup \{\infty\}$ be the $\ell$-valuation; that means for $r \in F_q[t] \setminus \{0\}$ we let $v_\ell(r) := m$ if $\ell^m | r$ and $\ell^{m+1} \nmid r$, $v_\ell$ induces a group homomorphism from $F_q(t)^\times$ to $\mathbb{Z}$, and $v_\ell(r) = \infty$ if and only if $r = 0$. We let $v_\infty$ be the valuation associated to $1/t$; that means $v_\infty(r/s) := \deg s - \deg r$ for any $r, s \in F_q[t] \setminus \{0\}$. The set of valuations of $F_q(t)$ is denoted by $V_{F_q}(t)$. For any valuation $\nu$, the $\nu$-adic norm of $r \in F_q(t)$ is defined as

$$|r|_\nu := \begin{cases} N(\ell)^{-v_\ell(r)} & \text{if } v = v_\ell \text{ for some irreducible polynomial } \ell, \\ q^{-v_\infty(r)} & \text{if } v = v_\infty. \end{cases}$$

For any valuation $\nu$, the $\nu$-adic completion of $K := F_q(t)$ is denoted by $K_\nu$. The ring of $\nu$-adic integers is denoted by $\mathcal{O}_\nu$, and the residue field of $K_\nu$ is denoted by $K(\nu)$. For an irreducible polynomial $\ell$, we let $K(\ell) := F_q[t]/(\ell) \simeq K(v_\ell)$. For any valuation $\nu$ of $F_q$, we let $\deg \nu := [K(\nu) : F_q]$; and so we have $\log_q N(f) = \sum_{v \in V_q} \nu(f) \deg v$ for any $f \in F_q[t]$. For $r_0(t) \in F_q[t]$, we let $D(r_0)$ to be either the set of irreducible factors of $r_0$ or $\{v_\ell \in V_{F_q}(t) | \ell \text{ is irreducible, } \ell^{|r_0|}\}$. For a finite subset $S$ of valuations of $F_q(t)$, we let $||r||_S := \max_{v \in S} |r|_v$. In this note for $h \in \text{GL}_{r_0}(F_q[t, 1/r_0(t)])$, we let $||h|| := \max_{i,j} \|h_{ij}\|_{D(r_0), \nu}$, where $h_{ij}$ is the $ij$-entry of $h$. We note that this norm depends on $r_0(t)$, and $r_0(t)$ should be understood from the context.

For a polynomial $r_0 \in F_p[t] \setminus \{0\}$ and positive integer $c_0$, we let $S_{r_0,c_0}$ be the set of all square-free polynomials $f(t) \in F_p[t]$ with prime factors $\ell_i(t)$ such that (1) $\ell_i(t) \nmid r_0(t)$, (2) $\deg \ell_i > 1$, (3) $\deg \ell_i \neq \deg \ell_j$ if $i \neq j$, and (4) $\deg \ell_i$ does not have a prime factor less than $c_0$.

For a ring $A$, $A^\times$ is the group of units of $A$ and $\text{Spec}(A)$ denotes the associated affine scheme; that means the points of this space are prime ideals of $A$. If $H$ is a group scheme defined over
a ring $A$ and $B$ is an $A$-algebra, then $H \otimes_A B$ denotes the group scheme on the fiber product $H \times_{\text{Spec } A} \text{Spec } B$. For a group scheme $H$ defined over $A$ and $\ell \in A \setminus A^\times$, we let $H_{\ell} := H \otimes_A A/\ell$. For a ring $A$, $(\text{GL}_n)_A$ denotes the $A$-group scheme given by the $n$-by-$n$ general linear group; so $(\text{GL}_n)_A = (\text{GL}_n)_{\mathbb{Z}} \otimes_{\mathbb{Z}} A$.

For an algebraic group $G$, $R_u(G)$ denotes its unipotent radical, and $\text{Lie } G$ is its Lie algebra.

1.5 Outline of proof and the key differences with the characteristic zero case

The general architecture of this article is as in Salehi Golsefidy–Varjú’s work [41] where Bourgain–Gamburd’s method [2] has been combined with Varjú’s multi-scale argument [48]. By now there are many excellent surveys and lecture notes that explain the key ideas of the groundbreaking result of Bourgain and Gamburd (see [8, 21, 25, 46]); so here we will be very brief on that part and focus on the main difficulties that were needed to be addressed.

As in the characteristic zero case, we start with understanding the group structure of $\pi_f(\Gamma)$ for a square-free polynomial $f(t) \in \mathbb{F}_p(t)$. By Weisfeiler’s strong approximation theorem [49], we have that, if irreducible factors $\ell_i(t)$ of $f(t)$ have large degrees, then

$$\pi_f(\Gamma) \cong \bigoplus_{i=1}^n \mathbb{G}_{\ell_i}(\mathbb{F}_N(\ell_i))$$

for some absolutely almost simple $\mathbb{F}_N(\ell_i)$-group $\mathbb{G}_{\ell_i}$ of dimension bounded by $n_0^2$. Note that, since $\mathbb{F}_p(t)$ has many subfields, it is inevitable to have an assumption on the trace field of $\Gamma$ to get such a result; this is why we assume that $\mathbb{F}_p(t)$ is the field generated by $\text{Tr}(\text{Ad}(\Gamma))$.

There is a positive number $c_0$ depending on $n_0$ such that all the factors $\mathbb{G}_{\ell_i}(\mathbb{F}_N(\ell_i))$ are $c_0$-quasi-random in the sense of Gowers [16]; this implies that for any irreducible representation $\rho$ of $\pi_f(\Gamma)$ we have that $\dim \rho \geq |\text{Im } \rho|^\varnothing$. Based on Sarnak–Xue trick [42] (see [16, 34]), it would be enough to find a good upper bound for the trace of $(T^{\pi_f(\Gamma)})^l$ for some positive integer $l = \Theta(n_0 \log (\pi_f(\Gamma)))$. This trace can be controlled in terms of the $L^2$-norm of $\pi_f[P_\Omega]^l$. Following Bourgain–Gamburd’s treatment, we look at the sequence of $\{\|\pi_f[P_\Omega]^{2m}\|_2\}_{m=1}^{\infty}$. It is easy to see that it is a decreasing sequence with a lower bound $\|P_{\pi_f(\Gamma)}\|_2$ (the $L^2$-norm of the probability counting measure on $\pi_f(\Gamma)$). Roughly what Bourgain and Gamburd showed is that, if at some step $\|\pi_f[P_\Omega]^{2m}\|_2$ is still not close enough to the lower bound $\|P_{\pi_f(\Gamma)}\|_2$ and does not get significantly smaller in the next step, there should be an algebraic reason: $\pi_f[P_\Omega]^{2m}$ should be concentrated on an approximate subgroup $X$; this roughly means $X$ is symmetric and almost close under multiplication. (We refer the reader to the above-cited surveys and lecture notes and [47] for a more thorough treatment of this subject; in this note we do not define approximate subgroups as they play an important role only at the background of our arguments). Breakthrough results of Breuillard–Green–Tao [9] and Pyber–Szabó [37] (these generalize works of Helfgott [19, 20]) say that an approximate subgroup of a finite simple group of Lie type with bounded rank is very close to being a subgroup. The multi-scale argument of Varjú [48] gives us an axiomatic way to reduce understanding of approximate subgroups of a finite product of finite groups to the same question for each one of the factors (see [48, Section 3]). One of Varjú’s assumptions on the factors (see [48, Section 3, Condition (A5)]) demands a type of bounded hierarchy for the subgroups of factors. The main idea
of existence of such bounded hierarchy of subgroups relies on Nori’s result \cite{35} which roughly says a subgroup of $GL_{n_0}(F_p)$ is more or less the $F_p$-points of an algebraic subgroup of $(GL_{n_0})_{F_p}$; and the mentioned hierarchy comes from the dimension of the associated algebraic subgroup. Clearly, this type of statement is not true for subgroups of $GL_{n_0}(F_{p^d})$ when $d$ gets arbitrarily large; consider $GL_{n_0}(F_p) \subseteq GL_{n_0}(F_{p^2}) \subseteq \cdots \subseteq GL_{n_0}(F_{p^d})$. So an important part of this work is to modify Varjú’s argument to work in our setting (note that we are presenting the overview of the proof in a backward fashion; and so this part of proof appears toward the end of the article in Section 4).

So far under the contrary assumption we have that $\pi_f[P_{l_0}]$ is concentrated on a proper subgroup $H$ of $\pi_f(\Gamma)$ for some positive integer $l_0 = \Theta(n_0(\log |\pi_f(\Gamma)|))$. Hence, we need to have a good understanding of proper subgroups of $\pi_f(\Gamma)$ and escape them in logarithmic number of steps. Here is another important difference with the case of $A = \mathbb{Z}[1/q_0]$ that we only partially address and is responsible for some of the additional technical assumptions in Theorem 1. For the case of $A = \mathbb{Z}[1/q_0]$, we have to understand proper subgroups of $GL_{n_0}(F_{\ell})$ where $\ell$ is a prime integer; and as it has been pointed out earlier, by a result of Nori \cite{35} such groups are more or less $F_{\ell}$-points of an algebraic subgroup. When $A = \mathbb{F}_p[t,1/r_0(t)]$, we need to understand subgroups of $GL_{n_0}(F_{N(\ell)})$, where $\ell(t) \in F_p[t]$ is an irreducible polynomial that does not divide $r_0(t)$. Using work of Larsen and Pink \cite{29}, we prove (see Subsection 2.2) that if $G_0$ is an absolutely almost simple group of adjoint type defined over a finite field $F_q$ and $H \subseteq G_0(F_q)$ is a proper subgroup, then either there exists a proper algebraic subgroup $H$ (with controlled complexity) of $G_0$ with $H \subseteq H(F_q)$, or there exists a subfield $F_{q'}$ and a model $G_1$ of $G_0$ defined over $F_{q'}$ (that means we can and will identify $G_1 \otimes F_{q'} F_q$ with $G_0$) such that

$$[G_1(F_{q'}) : G_1(F_{q'})] \subseteq H \subseteq G_1(F_{q'}).$$

Subgroups of the former type are called \textit{structural subgroups} while subgroups of the latter type are called \textit{subfield type subgroups}. Currently, we do not know how to escape subfield type subgroups, and this is why we need to add the extra technical assumptions on the largeness of prime factors of the degree of irreducible factors $\ell_i$ of $f$ in Theorem 1.

To escape structural subgroups, we use similar ideas as in Salehi Golsefidy–Varjú \cite{41}; but since representations of a simple group over a positive characteristic field are not necessarily completely reducible, we face extra difficulties that need to be resolved.

To be more precise we show that there is a polynomial $r_1(t)$ depending on $\Omega$ such that, if $f(t) \in F_p[t]$ is a square-free polynomial and $\gcd(f,r_1) = 1$, then (1) $\pi_f(\Gamma) = \prod_{i=1}^n \pi_{\ell_i}(\Gamma)$ where the functions $\ell_i$ are irreducible factors of $q$ and $\pi_{\ell_i}(\Gamma) \simeq G_{\ell_i}(F_{N(\ell_i)})$ for an absolutely almost simple $F_{N(\ell_i)}$-groups $G_{\ell_i}$; (2) if $H \subseteq \pi_f(\Gamma)$ is a proper subgroup such that $\pi_{\ell_i}(H)$ is a structural subgroup of $G_{\ell_i}(F_{N(\ell_i)})$ for any $i$, then the set of small lifts of $H$,

$$L_\delta(H) := \{h \in G(F_p[t,1/r_0(t)]) | \pi_f(h) \in H \text{ and } \|h\| < [G : H]^{\delta}\}$$

is contained in a proper algebraic subgroup of $G$, where $\|h\| := \max_{i,j} \|h_{i,j}\|_{D(r_i)\cup\{v_\infty\}}$ (when $\delta$ is small enough depending on $\Omega$). So, we can escape proper subgroup $H$ of $\pi_f(\Gamma)$ where $\pi_{\ell_i}(H)$ are structural subgroups if we manage to escape proper algebraic subgroups of $G$. Following \cite{41}, we show that there are finitely many non-trivial irreducible representations $\rho_i : G \rightarrow GL(V_i)$ and affine representations $\rho'_j : G \rightarrow Aff(W_j)$ of $G$ such that (1) the linear part of $\rho'_j$ is non-trivial and irreducible, (2) $G(F_p(t))$ does not fix any point of $W_j(F_p(t))$, (3) for any proper algebraic
subgroup \( \mathbb{H} \) of \( \mathbb{G} \) there are either \( i \) and \( v \in \mathbb{V}_i(\mathbb{F}_p(t)) \) such that \( \rho_i(\mathbb{H}(\mathbb{F}_p(t)))[v] = [v] \) where \([v]\) is the line in \( \mathbb{V}_i(\mathbb{F}_p(t)) \) that is spanned by \( v \) or \( j \) and \( w \in \mathbb{W}_j(\mathbb{F}_p(t)) \) which is fixed by \( \mathbb{H}(\mathbb{F}_p(t)) \) (see Proposition 28). Note that, since the representation \( \Lambda^\dim\mathbb{H} \) Ad is not necessarily completely reducible, we had to use affine representations even for the case where \( \mathbb{G} \) is (semi)simple; this is an issue that can occur only in the positive characteristic case. Having this result we can apply the same ping-pong type argument as in [41, Proposition 21] and find a finite symmetric subset \( \Omega' \) of \( \Gamma \) such that very few words in terms of \( \Omega' \) fix a line in one of their reducible representations \( \rho_i \); and then we deduce that \( \mathbb{P}_\Omega^{(l)}(\mathbb{H}(\mathbb{F}_p(t))) \leq e^{-O_{\Omega}(l)} \) for any proper algebraic subgroup \( \mathbb{H} \) of \( \mathbb{G} \). To be able to use \( \Omega' \) instead of \( \Omega \), we have to make sure that \( \pi_f((\Omega')) = \pi_f(\Gamma) \) when irreducible factors of \( f \) have large degree. Unfortunately at this point, we cannot do this; and here is another place that the technical assumption on the largeness of prime divisors of the degree of irreducible factors of \( f \) is needed. We suspect that this condition should not be needed here and the answer to the following question should be affirmative.

**Question 5.** Let \( \Omega, \Gamma, \) and \( \mathbb{G} \) be as in the hypotheses of Theorem 1. Let \( K := \mathbb{F}_p(t) \), \( V_K \) be the set of valuations of \( K \), \( \mathcal{O}_v \) be the ring of integers of the completion \( K_v \) of \( K \) with respect to a valuation \( v \), and \( D(r_0) := \{v|\ell | \ell \text{ is an irreducible factor of } r_0\} \). Let \( \tilde{\Gamma} \) be the closure of \( \Gamma \) in \( \prod_{v \in V_K \setminus D(r_0) \cup \{v_{\infty}\}} GL_{n_0}(\mathcal{O}_v) \). Then there is a finite subset \( \Omega'_0 \) of \( \Gamma \) such that

(1) \( \Omega'_0 \) freely generates a subgroup \( \Gamma' \) of \( \Gamma \);
(2) the closure \( \tilde{\Gamma}' \) of \( \Gamma' \) in \( \tilde{\Gamma} \) is open;
(3) for any proper algebraic subgroup \( \mathbb{H} \) of \( \mathbb{G} \) we have \( \mathbb{P}_\Omega^{(l)}(\mathbb{H}(\mathbb{F}_p(t))) \leq e^{-O_{\Omega}(l)} \) where \( \Omega' := \Omega'_0 \cup \Omega_{0}^{-1} \).

It is worth mentioning that we do find \( \Omega'_0 \) that satisfies (1) and (3); but we cannot make sure that the trace field of \( \Gamma' \) would be still \( \mathbb{F}_p(t) \). Hence, strong approximation does not imply (2). This issue does not occur over \( \mathbb{Q} \) as it does not have any non-trivial subfield.

Overall, we get the following result.

**Proposition 6** (Escape from proper subgroups). Let \( \Omega, \Gamma, \) and \( \mathbb{G} \) be as in the hypotheses of Theorem 1. Then there is a finite subset \( \Omega'_0 \subset \Gamma \), a square free polynomial \( r_1 \) divisible by \( r_0 \), and constants \( c_0 \) and \( \delta_0 \) depending only on \( \Omega \) such that the following holds.

(1) \( \Omega'_0 \) freely generates a free subgroup.
(2) For \( f \in S_{r_1,c_0} \), \( \pi_f((\Omega')) = \pi_f(\Gamma) \) where \( \Omega' := \Omega_0 \cup \Omega_{0}^{-1} \).
(3) For \( f \in S_{r_1,c_0} \), suppose \( H \leq \pi_f(\Gamma) \) is a proper subgroup with the property that \( \pi_{r}(\Gamma) \) is a structural subgroup of \( \pi_{r}(\Gamma) \) for every irreducible factor \( \ell \) of \( f \). Then for \( l \gg_{\Omega} \deg f \), we have

\[
\pi_f[\mathbb{P}_{r_0}^{(l)}](H) \leq [\pi_f(\Gamma) : H]^{-\delta_0}.
\]

As you can see using Proposition 6, we can only show escape from proper subgroups with structural factors. On the other hand, roughly speaking an arbitrary proper subgroup \( H \) can be embedded into a product of two groups, one with structural factors and the other with subfield subgroup factors. The extra technical condition on the largeness of prime factors of degrees of irreducible factors of \( f \) implies that the subgroup with subfield factors is relatively small; so it can be disregarded, and we get the desired result.
2 | A REFINEMENT OF A THEOREM BY LARSEN AND PINK

In this section, we point out how Larsen and Pink’s work [29] gives us a concrete understanding of proper subgroups of $\pi_f(\Gamma)$ where $\Gamma \subseteq \text{GL}_{n_0}(\mathbb{F}_p[1/r_0(t)])$ as in Theorem 1 (see Theorem 22). To avoid referring reader to the ideas in that article, we present an argument that uses only a couple of results from [29] as a black box. That said it is worth pointing out that most of the results in this section are hidden in the mentioned Larsen–Pink work.

2.1 General setting and strong approximation

Let $\Omega \subset \text{GL}_{n_0}(\mathbb{F}_{q_0}(t))$ be a finite symmetric set, and let $\Gamma = \langle \Omega \rangle$. Since $\Omega$ is finite, there exists a square-free polynomial $r_0 \in \mathbb{F}_{q_0}[t]$ such that $\Omega \subset \text{GL}_{n_0}(\mathbb{F}_{q_0}[t, 1/r_0(t)])$. The set of polynomials in $n_0^2$ variables with coefficients in $\mathbb{F}_{q_0}(t)$ which vanish on $\Gamma$ define a flat groups scheme $\mathcal{G}$ of finite type over $\mathbb{F}_{q_0}[t, 1/r_0]$. The Zariski closure $\mathcal{G}$ of $\Gamma$ in $(\text{GL}_{n_0})_{\mathbb{F}_{q_0}(t)}$ can be viewed as the generic fiber

$$\mathcal{G} \otimes_{\mathbb{F}_{q_0}[t, 1/r_0]} \mathbb{F}_{q_0}(t)$$

of $\mathcal{G}$. After possibly passing to a multiple of $r_0$, we may assume $\mathcal{G}$ is a smooth group scheme over $\mathbb{F}_{q_0}[t, 1/r_0]$ and that all of its fibers are of constant dimension. For any polynomial $f \in \mathbb{F}_{q_0}[t]$ that is coprime to $r_0$, we let $G_f := \mathcal{G} \otimes_{\mathbb{F}_{q_0}[t, 1/r_0]} \mathbb{F}_{q_0}[t]/\langle f \rangle$; and the reduction modulo $f$ homomorphism is denoted by $\pi_f : \mathcal{G}(\mathbb{F}_{q_0}[t, 1/r_0]) \to G_f(\mathbb{F}_{q_0}[t]/\langle f \rangle)$.

For an irreducible polynomial $\ell$ which does not divide $r_0$, let $K(\ell) := \mathbb{F}_{q_0}[t]/\langle \ell \rangle$. Then $G_\ell$ is an absolutely almost simple $K(\ell)$-group; and possibly after passing to a multiple of $r_0$, we can and will assume that all $G_\ell \otimes_{K(\ell)} \overline{K(\ell)}$ are of the same type $\Phi$ as $\ell$ ranges through irreducible polynomials in $\mathbb{F}_{q_0}[t]$ that do not divide $r_0$; this means there is an adjoint Chevalley $\mathbb{Z}$-group scheme $G^\text{Che}$ (we refer the reader to [45] for a thorough treatment of Chevalley group schemes) such that for any irreducible $\ell$ that does not divide $r_0$ we have a central isogeny

$$G_\ell \otimes_{K(\ell)} \overline{K(\ell)} \to G^\text{Che} \otimes_{\mathbb{Z}} K(\ell).$$

By Weisfeiler’s strong approximation theorem [49, Theorem 1.1], after possibly passing to a multiple of $r_0$, we have that if $f$ is a square-free polynomial coprime to $r_0$, then

$$\pi_f(\Gamma) = G_f(\mathbb{F}_{q_0}[t]/\langle f \rangle);$$

and by the Chinese Remainder Theorem $\mathbb{F}_{q_0}[t]/\langle f \rangle \simeq \bigoplus_{\ell \mid f, \ell \text{ irreducible}} K(\ell)$, which implies

$$G_f(\mathbb{F}_{q_0}[t]/\langle f \rangle) \simeq \prod_{\ell \mid f, \ell \text{ irreducible}} G_\ell(K(\ell)).$$

Throughout this paper, we may replace $r_0$ by the product of all irreducible polynomials of degree at most $C$ in $\mathbb{F}_{q_0}[t]$ for some $C \ll \Omega^1$ as necessary. For the remainder of this section, $f$ is a fixed square-free polynomial coprime to $r_0$.

To prove Proposition 6, we must understand proper subgroups of $\pi_f(\Gamma)$. In light of (2) and (3), we must study proper subgroups of $G_\ell(K(\ell))$ as $\ell$ ranges through all irreducible factors of $f$. 

2.2 The dichotomy of proper subgroups of $G_{\ell}(K(\ell'))$

In this section, the mentioned theorem of Larsen–Pink is stated and based on that we define structure type and subfield type subgroups.

Let $T$ be a maximal torus of $G$ and let $L$ be a minimal splitting field of $T$. Then $L$ is a finite extension of $\mathbb{F}_{q_0}(t)$ of degree say $D'$. Let $G_{\text{Che}}$ be the adjoint Chevalley $\mathbb{Z}$-group scheme of the same type $\Phi$ as $G \otimes_K L$, where $K := \mathbb{F}_{q_0}(t)$. Then there exists a central $L$-isogeny

$$G \otimes_K L \rightarrow G_{\text{Che}} \otimes \mathbb{Z} L.$$ 

After passing to a multiple of $r_0$, if needed, we can extend this isogeny to a central $O_L[1/r_0]$-isogeny

$$\phi : G_{\ell} \otimes_{\mathbb{F}_{q_0}[t,1/r_0]} O_L[1/r_0] \rightarrow G_{\text{Che}} \otimes \mathbb{Z} O_L[1/r_0],$$

where $O_L$ is the integral closure of $\mathbb{F}_{q_0}[t]$ in $L$. For an irreducible polynomial $\ell'$ coprime to $r_0$, let $I \in \text{Spec}(O_L)$ be in the fiber over $\langle \ell' \rangle$; that means $I \cap \mathbb{F}_{q_0}[t] = \langle \ell' \rangle$. Then $K(\ell') := \mathbb{F}_{q_0}[t]/\langle \ell' \rangle$ can be embedded into $L(I) := O_L/I$, and

$$[L(I) : K(\ell')] \leq [L : K] \ll 1.$$ 

Hence, we obtain an induced central $L(I)$-isogeny

$$\phi_{\ell'} : G_{\ell} \otimes_{K(\ell')} L(I) \rightarrow G_{\text{Che}} \otimes \mathbb{Z} L(I).$$

With this preparation, we mention a theorem of Larsen and Pink which is key in understanding proper subgroups of $G_{\ell}(K(\ell'))$.

**Theorem 7** [29, Theorem 0.6]. Let $G_{\text{Che}}^0$ be an adjoint Chevalley $\mathbb{Z}$-group scheme with simple root system $\Phi_0$. Then there exists a representation

$$\rho : G_{\text{Che}}^0 \rightarrow (\text{GL}_{n_0'})_\mathbb{Z}$$

with the following property: Let $H$ be a finite subgroup of $G_{\text{Che}}^0(\overline{\mathbb{F}_p})$ where $G_{\text{Che}}^0 = G_{\text{Che}}^0 \otimes \mathbb{Z} \overline{\mathbb{F}_p}$ is the geometric fiber of $G_{\text{Che}}^0$ over $p$ where $p$ is a prime more than 3. Then either there exists a proper subspace $W \subset (\overline{\mathbb{F}_p})^{n_0}$ that is stable under $\rho(H)$ but not $\rho(G_{\text{Che}}^0(\overline{\mathbb{F}_p}))$, or there exists a finite field $\mathbb{F}_q \subset \overline{\mathbb{F}_p}$ and a model $G_0$ of $G_{\text{Che}}^0$ over $\mathbb{F}_q$ (that means an $\mathbb{F}_q$-group $G_0$ such that $G_0 \otimes_{\mathbb{F}_q} \overline{\mathbb{F}_p} \cong G_{\text{Che}}^0$) such that the commutator subgroup of $G_0(\mathbb{F}_q)$ is simple and

$$[G_0(\mathbb{F}_q) : G_0(\mathbb{F}_q)] \leq H \leq G_0(\mathbb{F}_q).$$

**Definition 8.** Subgroups that satisfy the first condition are said to be of structural type while subgroups that satisfy the latter condition are said to be of subfield type.

If for an irreducible polynomial $\ell'$ that does not divide $r_0$, $H \subseteq \pi_{\ell'}(\Gamma) \cong G_{\ell}(K(\ell'))$ is a subgroup such that $\phi_{\ell'}(H)$ is a subfield type subgroup (respectively, structural type subgroup) of $G_{\text{Che}}^0(\overline{\mathbb{F}_p})$, then we call $H$ a subfield (respectively, structural) type subgroup of $\pi_{\ell'}(\Gamma)$. 
2.3 Refiner description of subfield type subgroups of $G_\ell(K)$

In this section, we focus on subfield type subgroups of $G_\ell(K)$; and we get a connection between the model $G_0$ given in Theorem 7 and $G_\ell$. We prove a stronger result (see Proposition 9) which is of independent interest.

A subfield type subgroup $H$ of $G_{\text{Che}}(\mathbb{F}_p)$ gives us a finite field $F_H$ and a model $G_H$ of $G_{\text{Che}} \otimes_{\mathbb{F}_p} \mathbb{F}_p$ over $F_H$. Proposition 9 implies that if $H_1 \subseteq H_2$ are two subfield subgroups of $G_{\text{Che}}(\mathbb{F}_p)$ and $p$ is large enough, then $F_{H_1} \subseteq F_{H_2}$ and $G_{H_1}$ is a model of $G_{H_2}$ over $F_{H_1}$. This statement can be proved by the virtue of the argument given by Larsen and Pink. Here, we give an independent self-contained proof.

**Proposition 9.** For $i = 1, 2$, let $G_i$ be an absolutely almost simple group defined over a finite field $F_{q_i} \subseteq \mathbb{F}_p$. Suppose the functions $F_{q_i}$ are of characteristic $p > 5$, $q_1 > 9$, and that $G_2$ is of adjoint type. Suppose $\bar{\theta} : G_1 \otimes_{F_{q_1}} \mathbb{F}_p \to G_2 \otimes_{F_{q_2}} \mathbb{F}_p$ is an isogeny such that

$$\bar{\theta}(G_1(F_{q_1})) \subseteq G_2(F_{q_2}).$$

Then $F_{q_1} \subseteq F_{q_2}$ and there exists an isogeny $\theta : G_1 \otimes_{F_{q_1}} F_{q_2} \to G_2$ such that $\theta \otimes \text{id}_{F_{q_2}} = \bar{\theta}$.

By a theorem of Lang [23, Theorem 35.2], $G_1$ is quasi-split; that means $G_1$ has a Borel subgroup $B_1$ defined over $F_{q_1}$. By [1, Section 6.5(3)], there is a maximal $F_{q_1}$-split torus $S_1$ such that

$$B_1 = C_{G_1}(S_1) \cdot R_u(B_1),$$

where $R_u(B_1)$ is the unipotent radical of $B_1$. Since $B_1$ is a Borel subgroup, $T_1 = C_{G_1}(S_1)$ is a maximal torus. Since $S_1$ is defined over $F_{q_1}$, $T_1$ is defined over $F_{q_1}$.

Let $G_i = G_i \otimes_{F_{q_i}} \mathbb{F}_p$ for $i = 1, 2$, $S_2 = \bar{\theta}(S_1 \otimes_{F_{q_1}} \mathbb{F}_p)$, $T_2 = \bar{\theta}(T_1 \otimes_{F_{q_1}} \mathbb{F}_p)$, and $H_2 = \bar{\theta}(B_1 \otimes_{F_{q_1}} \mathbb{F}_p)$. Let $q_i = \text{Lie}(G_i)$ for $i = 1, 2$; it is worth pointing out that we view the functions $q_i$ as functors from $F_{q_i}$-algebras to Lie $F_{q_i}$-algebras, and since the functions $G_i$ are smooth $F_{q_i}$-group schemes, $q_i(A)$ is naturally isomorphic to $q_i \otimes_{F_{q_i}} A$ where $q_i := q_i(F_{q_i})$. Note that since $\bar{\theta}$ is an isogeny, we have an isomorphism

$$d \bar{\theta} : q_1(\mathbb{F}_p) \to q_2(\mathbb{F}_p)$$

which satisfies the identity

$$d \bar{\theta}(\text{Ad}(g_1)(x_1)) = \text{Ad}(\bar{\theta}(g_1))(d \bar{\theta}(x_1)), \quad (5)$$

for all $g_1 \in G_1(\mathbb{F}_p)$ and $x_1 \in q_1(\mathbb{F}_p)$. By [1, Corollaries 9.2 and 11.12] and [12, A.2.8], we have

$$\bar{\theta}(C_{G_1}(S_1 \otimes_{F_{q_1}} \mathbb{F}_p)) = C_{G_2}(S_2)$$

is an $\mathbb{F}_p$-torus, $T_2 = C_{G_2}(S_2)$ is a maximal $\mathbb{F}_p$-torus, and $\text{Lie}(T_1) = C_{G_1}(S_1)$.

For a torus $S$ defined over a perfect field $F$, let $X^*(S)$ be the group of characters of $S$; that means $\text{Hom}(S \otimes_F \mathbb{F}, (\text{GL}_1)_F)$). It is well-known that $X^*(S)$ is isomorphic to $\mathbb{Z}^{\dim S}$ as an abelian group and the absolute Galois group $\text{Gal}(\overline{F}/F)$ acts linearly on $X^*(S)$ (see [1, Chapter III, Section 8]). Suppose
$S$ is a subgroup of an algebraic group $H$; then $\Phi(H, S) \subseteq X^*(S)$ denotes the set of roots of $H$ relative to $S$. For $\alpha \in \Phi(H, S)$, let

$$\mathfrak{h}_\alpha(A) := \{x \in \mathfrak{h}(A) | \forall s \in S(A), \text{Ad}(s)(x) = \alpha(s)x\}$$

be the root space associated with $\alpha$. We note that if $\alpha$ is defined over $F$ (this is equivalent to saying $\alpha$ is invariant under the action of the absolute Galois group $\text{Gal}(\overline{F}/F)$), then $\mathfrak{h}_\alpha$ is defined over $F$.

Let us also recall that, $\tilde{\Phi}$ induces injective group homomorphism from $\tilde{\Phi}^*: X^*(\tilde{S}_2) \to X^*(\tilde{S}_1)$ and $\tilde{\Phi}^*: X^*(\tilde{T}_2) \to X^*(\tilde{T}_1)$.

**Lemma 10.** $\tilde{\Phi}^*$ induces bijections $\Phi(\tilde{G}_2, \tilde{S}_2) \to \Phi(\tilde{G}_1, \tilde{S}_1)$ and $\Phi(\tilde{G}_2, \tilde{T}_2) \to \Phi(\tilde{G}_1, \tilde{T}_1)$. Moreover, $d\tilde{\Phi}$ induces isomorphisms $\mathfrak{g}_{1,\tilde{\Phi}^*}(\tilde{F}_p) \to \mathfrak{g}_{2,\alpha}(\tilde{F}_p)$ for $\alpha \in \Phi(\tilde{G}_2, \tilde{S}_2)$ or $\Phi(\tilde{G}_2, \tilde{T}_2)$.

**Proof.** We note that the root space decomposition of $\mathfrak{g}_2$ relative to $\tilde{S}_2$ gives us

$$\mathfrak{g}_2(\tilde{F}_q) = \mathfrak{t}_2(\tilde{F}_q) \oplus \left( \bigoplus_{\beta \in \Phi(\tilde{G}_2, \tilde{S}_2)} \mathfrak{g}_{2,\beta}(\tilde{F}_q) \right).$$

Suppose $x_{2,\alpha} \in \mathfrak{g}_{2,\alpha}(\tilde{F}_p)$, and $x_1 \in \mathfrak{g}_{1}(\tilde{F}_p)$ such that $d\tilde{\Phi}(x_1) = x_{2,\alpha}$. By (5) for every $s_1 \in \tilde{S}_1(\tilde{F}_p)$ and $\alpha \in \Phi(\tilde{G}_2, \tilde{S}_2)$, we have

$$d\tilde{\Phi}(\text{Ad}(s)(x_1)) = \text{Ad}(\tilde{\Phi}(s_1))(d\tilde{\Phi}(x_1)) = (\tilde{\Phi}^*(\alpha))(s_1)d\tilde{\Phi}(x_1) = d\tilde{\Phi}((\tilde{\Phi}^*(\alpha))(s_1)x_1);$$

this implies $(\tilde{\Phi}^*(\alpha)(s_1)x_1 = \text{Ad}(s)x_1$ as $d\tilde{\Phi}$ is an isomorphism. Therefore, $\tilde{\Phi}^*(\alpha) \in \Phi(\tilde{G}_1, \tilde{S}_1)$ and $d\tilde{\Phi}(\mathfrak{g}_{-1,\tilde{\Phi}^*}(\tilde{F}_p)) \subseteq \mathfrak{g}_{-1,\tilde{\Phi}^*}(\tilde{F}_p)$. By comparing dimensions, we see that $\tilde{\Phi}$ induces a bijection from $\Phi(\tilde{G}_2, \tilde{S}_2)$ to $\Phi(\tilde{G}_1, \tilde{S}_1)$ and $d\tilde{\Phi}$ induces an isomorphism from $\mathfrak{g}_{-1,\tilde{\Phi}^*}(\tilde{F}_p)$ to $\mathfrak{g}_{-1,\tilde{\Phi}^*}(\tilde{F}_p)$. The argument is similar for the second assertion. \[\square\]

**Lemma 11.** For every $\alpha \in \Phi(\tilde{G}_1, \tilde{S}_1)$, $\dim \mathfrak{g}_{-1,\tilde{\Phi}^*} \leq 3$.

**Proof.** Let us recall that if $H$ is a quasi-split absolutely almost simple $k$-group, then there is a Galois extension $l$ of $k$ such that $H \otimes_k l$ is a split group and $\text{Gal}(l/k)$ can be embedded into the group of symmetries of the Dynkin diagram of $H \otimes_k \tilde{F}_1$; in particular, $\text{Gal}(l/k)$ is isomorphic to $\{1, \mathbb{Z}/2\mathbb{Z}, \mathbb{Z}/3\mathbb{Z}, \text{or } S_3\}$. By Lang’s theorem [23, Theorem 35.2], $G_i$ is quasi-split over $\mathbb{F}_{q_i}$ for $i = 1, 2$. Therefore by the above discussion and the fact that finite extensions of $\mathbb{F}_{q_i}$ are cyclic, we have that there is a Galois extension $F_1$ of $\mathbb{F}_{q_1}$ such that $G_1 \otimes_{\mathbb{F}_{q_1}} F_1$ splits and $| \text{Gal}(F_1/\mathbb{F}_{q_1}) | \leq 3$. For each $\alpha \in \Phi(\tilde{G}_1, \tilde{S}_1)$, we have

$$\dim \mathfrak{g}_{-1,\tilde{\Phi}^*} = |\{\tilde{\alpha} \in \Phi(\tilde{G}_1, \tilde{T}_1) | \tilde{\alpha}|_{\tilde{S}_1} = \alpha\}|$$

and $\text{Gal}(F_1/\mathbb{F}_{q_1})$ acts transitively on the set

$$\{\tilde{\alpha} \in \Phi(\tilde{G}_1, \tilde{T}_1) | \tilde{\alpha}|_{\tilde{S}_1} = \alpha\},$$

which implies the lemma (see [44, Proposition 15.5.3]). \[\square\]
Proposition 12. In the above setting, if \( q_1 > 9 \), then \( \mathbb{F}_{q_1} \subseteq \mathbb{F}_{q_2} \).

Proof. Let \( \{\alpha_1, \alpha_2, \ldots, \alpha_r\} \) be a set of simple roots of \( S_1 \), and \( \{\alpha'_1, \ldots, \alpha'_r\} \) the corresponding coroots. Then for any \( t_1, t_2, \ldots, t_r \in \mathbb{F}_{q_1} \),

\[
\text{Tr}(\text{Ad}(\tilde{\Theta}(\Pi_{i=1}^r \alpha'_i(t_i)))) \in \mathbb{F}_{q_2}
\]
since \( \tilde{\Theta}(G_{1}(\mathbb{F}_{q_1})) \subseteq G_2(\mathbb{F}_{q_2}) \). On the other hand, by (5), we have

\[
\text{Tr}(\text{Ad}(\Pi_{i=1}^r \alpha'_i(t_i))) = \text{Tr}(\text{Ad}(\tilde{\Theta}(\Pi_{i=1}^r \alpha'_i(t_i))));
\]
and so

\[
\sum_{\beta \in \Phi(G_1, S_1)} \dim_{\mathfrak{g}_1, \beta} \Pi_{i=1}^r \langle \alpha'_i, \beta \rangle \in \mathbb{F}_{q_2}.
\] (6)

Note that for each \( i = 1, 2, \ldots, r \), and any root \( \beta \), \( \langle \alpha'_i, \beta \rangle \) is a Cartan integer and hence is at most 3 in absolute value. By Lemma 11, \( \dim_{\mathfrak{g}_1, \beta} \leq 3 \). The proposition will be proved with the following series of lemmas.

Lemma 13. Suppose \( f(t) \in \mathbb{F}_p[t^{\pm 1}] \) is a nonconstant polynomial, \( (\deg_t f + \deg_{t^{-1}} f)^2 < q \), and \( f(\mathbb{F}_q) \subseteq \mathbb{F}_{q'} \); then \( \mathbb{F}_q \subseteq \mathbb{F}_{q'} \).

Proof. For each \( a \in \mathbb{F}_{q'} \), there are at most \( (\deg_t f + \deg_{t^{-1}} f) \) elements \( b \in \mathbb{F}_q \) such that \( f(b) = a \). Hence, \( |f(\mathbb{F}_q)| \geq q/(\deg_t f + \deg_{t^{-1}} f) \). Suppose \( F \) is the field generated by \( f(\mathbb{F}_q) \); then \( \log_p |F| \) divides \( \log_p q \) and \( \log_p q \leq \log_p |F| + \log_p(\deg_t f + \deg_{t^{-1}} f) \). If \( F \neq \mathbb{F}_q \), then the above argument implies \( (1/2) \log_p q \leq \log_p(\deg_t f + \deg_{t^{-1}} f) \). This contradicts the assumption that \( q > (\deg_t f + \deg_{t^{-1}} f)^2 \). \( \square \)

Lemma 14. Suppose \( f \in \mathbb{F}_p[t_{1}^{\pm 1}, \ldots, t_{r}^{\pm 1}] \) is a non-zero polynomial and

\[
\max_i(\deg_{t_i} f + \deg_{t_{-i}} f) + 1 < q;
\]
then \( f(\mathbb{F}_q^x, \ldots, \mathbb{F}_q^x) \neq 0 \).

Proof. This can easily be proved by induction on \( r \). \( \square \)

Lemma 15. Suppose \( f \in \mathbb{F}_p[t_1^{\pm 1}, \ldots, t_r^{\pm 1}] \) is a non-zero polynomial such that \( f(\mathbb{F}_q^x, \ldots, \mathbb{F}_q^x) \) is contained in \( \mathbb{F}_{q'} \), and \( \max_i(\deg_{t_i} f + \deg_{t_{-i}} f)^2 < q \); then \( \mathbb{F}_q \subseteq \mathbb{F}_{q'} \).

Proof. Since \( f \) is nonconstant, there exists some index \( i_0 \) where \( \deg_{t_{i_0}^{\pm 1}} f \neq 0 \). Without loss of generality we can and will assume that \( i_0 = r \). By Lemma 14, there is a choice of constants \( a_1, \ldots, a_{r-1} \in \mathbb{F}_q^x \) such that \( f(a_1, \ldots, a_{r-1}, t_r) \) is a nonconstant polynomial in \( t_r \). By Lemma 13, we are done. \( \square \)

Proposition 12 follows from (6) and Lemma 15. \( \square \)
We must now prove the existence of the isogeny $\theta$.

**Proposition 16.** If $q_1 > 7$ and $p > 5$, then $d \tilde{\theta}$ induces an isomorphism between $\tilde{\mathfrak{g}}_{1}(F_{q_2})$ and $\tilde{\mathfrak{g}}_{2}(F_{q_2})$.

We distinguish two cases depending on whether or not $\mathfrak{g}_1$ has a non-trivial center.

**Lemma 17.** Let $p > 5$. Suppose $G$ is an absolutely almost simple $F_q$-group and that $G$ is not of type $A_{n_{p-1}}$ for some positive integer $n$. Assume that:

1. $M \subseteq \tilde{\mathfrak{g}}(\overline{F}_p)$ is an $F_{q'}$-subspace where $F_q \subseteq F_{q'}$,
2. $\dim_{F_{q'}} M = \dim_{F_p} \tilde{\mathfrak{g}}(\overline{F}_p)$, and
3. $M$ is $G(F_q)$-invariant.

Then there exists $0 \neq \lambda \in \overline{F}_p$ such that $M = \lambda \tilde{\mathfrak{g}}(F_{q'})$.

**Proof.** Since $G$ is not of type $A_{n_{p-1}}$, $\tilde{\mathfrak{g}}(\overline{F}_p)$ is a simple $G(F_q)$-module. By [49, Corollary 4.6], $\tilde{\mathfrak{g}}(\overline{F}_p)$ is a simple $G(F_q)$-module. Let $\{\alpha_i\}$ be an $F_{q'}$-basis of $\overline{F}_p$, so we have

$$\tilde{\mathfrak{g}}(\overline{F}_p) = \bigoplus_{i \geq 0} \alpha_i \tilde{\mathfrak{g}}(F_{q'}).$$

Let $p_{r_i} : M \to \alpha_i \tilde{\mathfrak{g}}(F_{q'})$ be the projection morphism onto the $i^{th}$ component. Since $M$ and $\tilde{\mathfrak{g}}(\overline{F}_p)$ are both $G(F_q)$-invariant, $p_{r_i}$ is an $F_{q'}$-linear $G(F_q)$-module homomorphism. Again by [49, Corollary 4.6], $\tilde{\mathfrak{g}}(F_{q'})$ is a simple $F_{q'}[\text{Ad}(G(F_q))]$-module and hence $p_{r_i}$ is either trivial or surjective for each $i$. Since $\dim_{F_{q'}} M = \dim_{F_p} \tilde{\mathfrak{g}}(\overline{F}_p)$, either $p_{r_i} = 0$ or $p_{r_i}$ is an isomorphism.

If $p_{r_i}$ and $p_{r_j}$ are isomorphisms, then $p_{r_i} \circ p_{r_j}^{-1} \in \text{Aut}_{G(F_q)\text{-Mod}}(\tilde{\mathfrak{g}}(F_{q'}))$. Then there exists a non-zero element $\alpha_{i,j} \in F_{q'}$ such that $p_{r_i} \circ p_{r_j}^{-1}(x) = \lambda_{i,j} x$ for all $x \in \tilde{\mathfrak{g}}(F_{q'})$. Hence, if $j_0$ is a fixed index for which $p_{r_{j_0}}$ is an isomorphism, we have

$$M = \left( \sum_i \alpha_i \lambda_{i,j_0} \right) \tilde{\mathfrak{g}}(F_{q'}). \quad \square$$

In the case when $G$ is of type $A_{n_{p-1}}$ we have the following.

**Lemma 18.** Suppose $p > 5$ and $G$ is of type $A_{n_{p-1}}$ for some positive integer $n$. Suppose $F_q \subseteq F_{q'}$ and suppose:

1. $M \subseteq \tilde{\mathfrak{g}}(\overline{F}_p)$ is an $F_{q'}$-subspace,
2. $M$ is $\tilde{G}(F_q)$-invariant, and
3. $\dim_{F_q} (M + z(\overline{F}_p))/z(\overline{F}_p) = \dim_{F_p} \tilde{\mathfrak{g}}(\overline{F}_p)/z(\overline{F}_p)$ where $z$ is the center of $\tilde{\mathfrak{g}}$.

Then there exists $0 \neq \lambda \in \overline{F}_p$, such that $M + z(\overline{F}_p) = \lambda \tilde{\mathfrak{g}}(F_{q'}) + z(\overline{F}_p)$.

**Proof.** In this case, $\tilde{\mathfrak{g}}(\overline{F}_p)/z(\overline{F}_p)$ is a simple $\tilde{G}(\overline{F}_p)$-module. Again by [49, Corollary 4.6], $\tilde{\mathfrak{g}}(\overline{F}_p)/z(\overline{F}_p)$ is a simple $G(F_q)$-module. An argument similar to the proof of Lemma 17 establishes the claim. \square
Proof of Proposition 16. Let $M = d\tilde{\theta}^{-1}(\mathfrak{g}_2(F_{q_2})) \subseteq \mathfrak{q}_1(\overline{F}_p)$. If $G_1$ and $G_2$ are not of type $A_{n-1}$, then Lemma 17 finishes the proof. So, assume $G_1$ is of type $A_{n-1}$. Then $\dim_{F_{q_2}} M = \dim_{F_{q_2}} \mathfrak{q}_1(\overline{F}_p)$. Note that $d\tilde{\theta}$ induces an isomorphism between $\mathfrak{z}_1(\overline{F}_p)$ and $\mathfrak{z}_2(\overline{F}_p)$, and
\[
\dim_{F_{q_2}} \left(\mathfrak{g}_2(F_{q_2}) + \mathfrak{z}_2(\overline{F}_p)\right)/\mathfrak{z}_2(\overline{F}_p) = \dim_{F_{q_2}} \mathfrak{q}_1(\overline{F}_p) - 1
\]
and hence
\[
\dim_{F_{q_2}} \left(M + \mathfrak{z}_1(\overline{F}_p)\right)/\mathfrak{z}_1(\overline{F}_p) = \dim_{F_{q_2}} \mathfrak{q}_1(\overline{F}_p)/\mathfrak{z}_1(\overline{F}_p).
\]
By Lemma 18, there exists $0 \neq \lambda \in F_{q_2}$ such that $M + \mathfrak{z}_1(\overline{F}_p) = \lambda \mathfrak{q}_1(F_{q_2}) + \mathfrak{z}_1(\overline{F}_p)$. Since $[\mathfrak{g}_i(F_{q_2}), \mathfrak{g}_i(F_{q_2})] = \mathfrak{g}_i(F_{q_2})$ for $i = 1, 2$, we have $[M, M] = \lambda^2 \mathfrak{g}_1(F_{q_2})$ and
\[
[M, M] = d\tilde{\theta}^{-1}(\mathfrak{g}_2(F_{q_2}), \mathfrak{g}_2(F_{q_2})) = d\tilde{\theta}^{-1}(\mathfrak{g}_2(F_{q_2})) = M.
\]
Hence, $M = [M, M] = \lambda^4 \mathfrak{g}_1(F_{q_2}) = \lambda^2 \mathfrak{g}_1(F_{q_2})$. This shows $\mathfrak{g}_1(F_{q_2}) = \lambda^2 \mathfrak{g}_1(F_{q_2})$ and hence $M = \mathfrak{g}_1(F_{q_2})$. □

Corollary 19. $d\tilde{\theta}$ induces isomorphisms between
\[
\mathfrak{t}_1(F_{q_2}) \text{ and } \mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2(\overline{F}_p),
\]
and
\[
\mathfrak{g}_1(\tilde{\theta}^\ast(\beta))(F_{q_2}) \text{ and } \mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2,\beta(\overline{F}_p), \forall \beta \in \Phi(\widetilde{G}_2, \widetilde{S}_2).
\]

Proof. By Proposition 16, we have
\[
d\tilde{\theta}(\mathfrak{g}_1(\tilde{\theta}^\ast(\beta))(F_{q_2})) \subseteq \mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2,\beta(\overline{F}_p),
\]
and similarly
\[
d\tilde{\theta}(\mathfrak{t}_1(F_{q_2})) \subseteq \mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2(\overline{F}_p).
\]
By comparing dimensions of $\mathfrak{g}_1(F_{q_2})$ and
\[
(\mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2(\overline{F}_p)) \oplus \left(\oplus_{\beta \in \Phi(\widetilde{G}_2, \widetilde{S}_2)}(\mathfrak{g}_2(F_{q_2}) \cap \mathfrak{z}_2,\beta(\overline{F}_p))\right),
\]
the result follows easily. □

Proof of Proposition 9. Note that the Galois group $\text{Gal}(\overline{F}_p/F_{q_2})$ acts naturally on $G_1$, $G_2$, and their Lie algebras. The existence of such an isogeny
\[
\theta : G_1 \otimes F_{q_2} \rightarrow G_2
\]
is equivalent to $\tilde{\theta}$ commuting with the action of $\text{Gal}(\overline{F}_p/F_{q^2})$. More precisely, it suffices to show that for any $g_1 \in G_1(\overline{F}_p)$ and $\sigma \in \text{Gal}(\overline{F}_p/F_{q^2})$, $\sigma(\tilde{\theta}(g_1)) = \tilde{\theta}(\sigma(g_1))$.

Recall that by (5), we have

$$d\tilde{\theta}((\text{Ad}(g_1))(x_1)) = \text{Ad}(\tilde{\theta}(g_1))(d\tilde{\theta}(x_1))$$

(7)

for every $g_1 \in G_1(\overline{F}_p)$ and $x_1 \in \mathfrak{g}_1(\overline{F}_p)$. Since $d\tilde{\theta}$ restricts to an isomorphism from $\mathfrak{g}_1(F_{q^2})$ to $\mathfrak{g}_2(F_{q^2})$ by Proposition 16, we have

$$\sigma(d\tilde{\theta}((\text{Ad}(g_1))(x_1))) = d\tilde{\theta}(\sigma(\text{Ad}(g_1))(x_1)).$$

(8)

Since the adjoint representation of $G_1$ is defined over $\mathbb{F}_{q_1} \subseteq \mathbb{F}_{q^2}$, we have

$$\sigma(\text{Ad}(g_1)(x_1)) = \text{Ad}(\sigma(g_1))(\sigma(x_1)).$$

(9)

By (7), (8), and (9), we deduce

$$\sigma(d\tilde{\theta}((\text{Ad}(g_1))(x_1))) = d\tilde{\theta}(\sigma(\text{Ad}(g_1))(\sigma(x_1)))$$

$$= \text{Ad}(\sigma(\tilde{\theta}(g_1)))(d\tilde{\theta}(\sigma(x_1))).$$

(10)

Since $G_2$ is defined over $\mathbb{F}_{q^2}$, by Proposition 16

$$\sigma(\text{Ad}(\tilde{\theta}(g_1))(d\tilde{\theta}(x_1))) = \text{Ad}(\sigma(\tilde{\theta}(g_1)))(d\tilde{\theta}(\sigma(x_1))).$$

(11)

Therefore by (10) and (11), we have

$$\text{Ad}(\sigma(\tilde{\theta}(g_1)))(d\tilde{\theta}(\sigma(x_1))) = \text{Ad}(\sigma(\tilde{\theta}(g_1)))(d\tilde{\theta}(\sigma(x_1)))$$

and hence

$$\text{Ad}(\sigma(\tilde{\theta}(g_1))) = \text{Ad}(\sigma(\tilde{\theta}(g_1))).$$

Since $G_2$ is an adjoint group, $\tilde{\theta}(\sigma(g_1)) = \sigma(\tilde{\theta}(g_1))$ which proves the claim. □

2.4 Refiner description of structure type subgroups of $G_e(K(\ell))$

Suppose $H$ is a structural subgroup of $G_e(K(\ell))$; it means there is a proper subgroup $\mathbb{H}_e$ of $G_e \otimes_{K(\ell)} K(\ell)$ such that $H \subseteq \mathbb{H}_e(K(\ell))$. In this section, we use almost the full strength of Larsen and Pink’s result to give a control on the complexity of $\mathbb{H}_e$ and its field of definition.

**Definition 20.** Suppose $F$ is an algebraically closed field and $(\mathbb{A}^n)_F$ is the affine space over $F$. The complexity of a Zariski closed subset $X$ of $F^n$ is the minimum of positive integers $D$ such that there are at most $D$ polynomials $p_i$ of degree at most $D$ in $F[x_1, \ldots, x_n]$ such that $X$ is the set of common zeros of the functions $p_i$. 

It is worth pointing out that one can use the language of algebraic geometry and use degree of the closure of $X$ in the projective space $\mathbb{P}^n$ to capture the above-mentioned complexity of $X$; but we find it easier for the reader to work with the above-mentioned quantity.

**Proposition 21.** Suppose $\Gamma$, $G$, $G_\ell$, and $K(\ell)$ are as above; that means $\Gamma$ is a finitely generated subgroup of $\text{GL}_{n_0}(\mathbb{F}_{q_0}[t, 1/r_0(t)])$ where $q_0$ is a power of a prime $p > 3$ and the field generated by $\text{Tr}(\Gamma)$ is $\mathbb{F}_{q_0}(t)$, $G$ is the Zariski-closure of $\Gamma$ in $(\text{GL}_{n_0})\mathbb{F}_{q_0}[t, 1/r_0(t)]$, for any irreducible polynomial $\ell \in \mathbb{F}_{q_0}[t]$ that does not divide $r_0(t)$, let $K(\ell) := \mathbb{F}_{q_0}[t]/\langle \ell \rangle$ and $G_\ell := \mathcal{G} \otimes_{\mathbb{F}_{q_0}[t, 1/r_0(t)]} K(\ell)$. Suppose $G := \mathcal{G} \otimes_{\mathbb{F}_{q_0}[t, 1/r_0(t)]} \mathbb{F}_{q_0}(t)$ is an absolutely almost simple group, connected, simply connected group. Then if $H \subseteq \pi_\ell(\Gamma)$ is a proper structural subgroup for some irreducible polynomial $\ell$ with $\deg \ell \gg_1$, there is a proper algebraic subgroup $H$ of $G_\ell$ such that

1. the complexity of $H$ is bounded by a function of $\Gamma$,
2. $H \subseteq H(K(\ell)) \subseteq G_\ell(K(\ell))$.

**Proof.** As it has been mentioned earlier (see Subsection 2.1), by Weisfeiler's strong approximation theorem there is a multiple $r_1$ of $r_0$ such that for any irreducible polynomial $\ell \in \mathbb{F}_{q_0}[t]$ that does not divide $r_1$, $\pi_\ell(\Gamma) = G_\ell(K(\ell))$. By the discussion at the beginning of Subsection 2.2, there are a finite separable extension $L$ of $\mathbb{F}_{q_0}(t)$, a multiple $r_2$ of $r_1$, and a central $\mathcal{O}_L[1/r_2(t)]$-isogeny

$$\phi : \mathcal{G} \otimes_{\mathbb{F}_{q_0}[t, 1/r_0(t)]} \mathcal{O}_L[1/r_2(t)] \to \mathcal{G}_{\text{Che}} \otimes \mathcal{O}_L[1/r_2(t)],$$

where $G_{\text{Che}}$ is an adjoint Chevalley $\mathbb{Z}$-group scheme and $\mathcal{O}_L$ is the integral closure of $\mathbb{F}_{q_0}[t]$ in $L$. By [29, Theorem 0.5], there is a scheme $T$ of finite type over Spec $\mathbb{Z}$ and a closed group scheme $H$ of $G_{\text{Che}} \times_{\text{Spec} \mathbb{Z}} T$ such that

1. for any geometric point $s'$ of $T$ over a geometric point $s$ of Spec $\mathbb{Z}$, the geometric fiber $H_{s'}$ is a proper subgroup of the geometric fiber $G_{s'}$ (here is the only place that we use the concept of geometric fiber; and so we do not give a precise definition of this concept. To illustrate what kind of objects these are, we only consider the example of a scheme $\mathcal{X}$ over Spec $A$ where $A$ is a ring; for any $p \in \text{Spec} A$, we let $k(p) := Q(A/p)$ be the field of fractions of the integral domain $A/p$, and then $\mathcal{X} \times_{\text{Spec} A} \text{Spec}(k(p))$ is a geometric fiber of $\mathcal{X}$. Vaguely if $\mathcal{X}$ is affine and given by polynomial equations with coefficients in $A$, we are looking at those polynomials modulo $p \in \text{Spec} A$ and then view them over the algebraic closure of the field of fractions of $A/p$);
2. if $H$ is a finite subgroup of $G_{\text{Che}}(\mathbb{F}_p)$ and $s' \in T$ is a point over $p\mathbb{Z}$, then either $H \subseteq H_{s'}(k(s'))$ where $k(s')$ is the residue field of $s'$ or there are a finite field $F_H$ and a model $G_H$ of $G_{\text{Che}} \otimes \mathbb{F}_p$ over $F_H$ such that

$$[G_{H}(F_H), G_{H}(F_H)] \subseteq H \subseteq G_{H}(F_H).$$

By [29, Proposition 2.3], there is a representation $\rho : G_{\text{Che}} \to (\text{GL}_{n_0})_\mathbb{Z}$ with the following property:

Suppose $H$ is a finite subgroup of $G_{\text{Che}}(\mathbb{F}_p)$ such that a subspace of $\mathbb{F}_p^{n_0}$ which is invariant under $H$ should also be invariant under $G_{\text{Che}}(\mathbb{F}_p)$; then $H \not\subseteq H_{s'}(k(s'))$ if $s'$ is a geometric point over $p\mathbb{Z}$. 

For an irreducible polynomial $\ell$ that does not divide $r_2$, let $I \in \text{Spec}(O_L)$ be in the fiber over $\langle \ell \rangle$. Set $L(I) := O_L/I$. Let $\phi_\ell$ be the representation induced by the composite of $\rho$ and $\phi$ over $I$:

$$\phi_I : G_\ell \otimes_{K(\ell)} L(I) \to (GL_{n_0})_{L(I)}.$$

If $H \subseteq G_\ell(K(\ell))$ is a proper structural subgroup, then by the above -mentioned results of Larsen–Pink there is a subspace $\tilde{W}$ of $\overline{F}_p^{q_0} = L(I)^{q_0}$ which is invariant under $H$ but not under $G_\ell(L(I))$ (via the representation $\phi_I$). Since $\tilde{W}$ is not invariant under $G_\ell(L(I))$, the intersection of $G_\ell \otimes_{K(\ell)} K(\ell)$ with the stabilizer of $\tilde{W}$ is a proper algebraic subgroup of $G_\ell \otimes_{K(\ell)} K(\ell)$. Hence, the intersection of $G_\ell \otimes_{K(\ell)} K(\ell)$ with all the $\text{Gal}(\overline{L(I)}/L(I))$-conjugates of the stabilizer of $\tilde{W}$ has a descent to a proper subgroup $\tilde{H}$ of $G_\ell \otimes_{K(\ell)} L(I)$; and since $\phi_I$ is defined over $L(I)$ and $H$ leaves $\tilde{W}$ invariant, $H \subseteq \tilde{H}(L(I))$. For any $\sigma \in \text{Gal}(L(I)/K(\ell))$, let $\tilde{H}^\sigma$ be the corresponding subgroup of $G_\ell \otimes_{K(\ell)} L(I)$; and let $H$ be the subgroup $\tilde{G}_\ell$ that is the descent of $\bigcap_{\sigma \in \text{Gal}(L(I)/K(\ell))} \tilde{H}^\sigma$. Since $H \subseteq G_\ell(K(\ell)) \cap \tilde{H}(L(I))$, we have that $H \subseteq H(K(\ell))$. We note that the complexity of the stabilizer of a subspace via $\phi_I$ has a uniform upper bound which depends on $\rho$ and $\phi$ and it is independent of $I$. Hence, the complexity of $\tilde{H}$ is bounded as a function of $\Gamma$; moreover complexity does not change under the Galois action, which means the complexity of $\tilde{H}^\sigma$ is bounded by the same function of $\Gamma$. As $|L(I) : K(\ell)| \leq |L : K| \ll \Gamma$, we deduce that the complexity of $H$ is bounded by a function of $\Gamma$.

Proposition 3.2 in [29] implies that, if $\deg \ell \gg \Gamma$, then $\tilde{H}(K(\ell))$ is a proper subgroup of $G_\ell(K(\ell))$). For convenience sake we include its short proof here. Since the complexity of $H$ is bounded by a function of $\Gamma$, the number of its irreducible components is $O_\Gamma(1)$. Hence, $|\tilde{H}(K(\ell))| \ll \Gamma |K(\ell)|^{\dim H}$. On the other hand, since the geometric fiber of $G_\ell$ is connected, by Lang–Weil [28, Theorem 1], $|G_\ell(K(\ell))| \gg \Gamma |K(\ell)|^{\dim G_\ell}$ (It is worth pointing out that an explicit formula for $|G_\ell(K(\ell))|$, based on invariant factors and $|K(\ell)|$ is known. So, the mentioned result of Lang–Weil is not really needed; but it is more conceptual). Hence for $|K(\ell)| \gg \Gamma$, $H(K(\ell))$ is a proper subgroup of $G_\ell(K(\ell))$.

\[ \Box \]

2.5 \hspace{1cm} \textbf{Refine version of the dichotomy of subgroups of $G_\ell(K(\ell))$}

Here, we summarize what we have proved in the previous sections in regard to subgroups of $\pi_\ell(\Gamma)$.

\textbf{Theorem 22.} Suppose $\Omega$, $\Gamma$, $G$, $G_\ell$, and $K(\ell)$ are as above; that means $\Gamma$ is a finitely generated subgroup of $GL_{n_0}(\mathbb{F}_{q_0}[1/r_0(t)])$ where $q_0 > 7$ is a power of a prime $p > 5$ and the field generated by $\text{Tr}(\Gamma)$ is $\mathbb{F}_{q_0}[1/r_0(t)], \mathcal{G}$ is the Zariski-closure of $\Gamma$ in $(GL_{n_0}\mathbb{F}_{q_0}[1/r_0(t)])$, $\ell$ is an irreducible polynomial in $\mathbb{F}_{q_0}[1/r_0(t)]$ that does not divide $r_0, K(\ell) := \mathbb{F}_{q_0}[1/\ell], and G_\ell := G \otimes_{\mathbb{F}_{q_0}[1/r_0(t)]} K(\ell)$. Suppose $G := G \otimes_{\mathbb{F}_{q_0}[1/r_0(t)]} \mathbb{F}_{q_0}(t)$ is an absolutely almost simple group, connected, simply connected group. Suppose $\deg \ell \gg \Gamma$; then for a subgroup $H$ of $\pi_\ell(\Gamma)$ we have that either

(1) $H$ is a structural type subgroup: there are a proper subgroup $H$ of $G_\ell$ and a polynomial $f_H \in K(\ell)[x_1, \ldots, x_{n_0}]$ such that

(a) the complexity of $H$ is bounded by a function of $\Gamma$, and $H \subseteq H(K(\ell)) \subsetneq G_\ell(K(\ell))$,

(b) $\deg f \ll \Gamma$, $f_H(H) = 0$, and for some $\gamma \in \Omega, f_H(\pi_\ell(\gamma)) \neq 0$,

(2) $H$ is a subfield type subgroup: there is a subfield $F_H$ of $K(\ell)$ and an algebraic group $G_{H}$ defined over $F_H$ such that
(a) $G_H \otimes_{F_H} K(\ell) = \text{Ad}(G_{\ell})$.

(b) $[G_H(F_H), G_H(F_H)] \subseteq \text{Ad} H \subseteq G_H(F_H)$.

**Proof.** By Proposition 21, if $\deg \ell \gg_1 1$ and $H$ is a structural type subgroup, there is a proper subgroup $\mathbb{H}$ of $G_{\ell}$ such that the complexity of $\mathbb{H}$ is $O(1)$, $H \subseteq \mathbb{H}(K(\ell)) \subseteq G_{\ell}(K(\ell))$. Suppose $\mathbb{H}$ is defined by polynomials $\{f_i \in K(\ell)[x_1, \ldots, x_n] | 1 \leq i \ll_1 1\}$, where $\deg f_i \ll_1 1$. Since $G_{\ell}(K(\ell)) \neq \mathbb{H}(K(\ell))$ and by strong approximation $G_{\ell}(K(\ell))$ is generated by $\pi_{\ell}(\Omega)$, there is $\gamma \in \Omega$ and $f_i$ such that $f_i(\pi_{\ell}(\gamma)) \neq 0$. This implies the claim if $H$ is a structural type subgroup.

If $H$ is subfield type subgroup, then there are a finite field $F_H \subseteq K(\ell)$ and a model $G_H$ of $\text{Ad} G_{\ell} \otimes_{K(\ell)} K(\ell)$ over $F$ such that $[G_H(F_H), G_H(F_H)] \subseteq \text{Ad} H \subseteq G_H(F_H)$.

Let $\tilde{G}_H$ be the simply connected cover of $G_H$. Then $\tilde{G}_H$ is a model of $G_{\ell} \otimes_{K(\ell)} K(\ell)$; and so the adjoint homomorphism is a central isogeny

$$\text{Ad} : \tilde{G}_H \otimes_{F_H} K(\ell) \rightarrow \text{Ad} G_{\ell} \otimes_{K(\ell)} K(\ell) \text{ and } \text{Ad}(\tilde{G}_H(F_H)) \subseteq \text{Ad} H \subseteq \text{Ad}(G_{\ell}(K(\ell))).$$

Hence by Proposition 9, $F_H \subseteq K(\ell)$ and the adjoint homomorphism has a descent to $K(\ell)$, $\text{Ad} : \tilde{G}_H \otimes_{F_H} K(\ell) \rightarrow \text{Ad} G_{\ell}$; and so $G_H := \text{Ad} \tilde{G}_H$ satisfies the claim.

### 2.6 A note on subfield type subgroups

In this section, we prove Proposition 23 which will be used later in modifying Varjú’s multi-scale argument.

**Proposition 23.** Let $q$ be a power of a prime $p > 5$, and $n \in \mathbb{Z}^+$. Suppose $\mathbb{H}$ is an absolutely almost simple, connected, adjoint type $\mathbb{F}_q$-group. Then

$$T([H(F_q), H(F_q)], H(F_{q^n})) := \{g \in H(F_p) | g^{-1}[H(F_q), H(F_q)]g \subseteq H(F_{q^n}) \} = H(F_{q^n}).$$

The main idea of the proof is similar to the proof of Proposition 16; but as the proof is fairly short, we reproduce it here.

**Lemma 24.** Suppose $F$ is a field, $V$ is a finite-dimensional $F$-vector space, $H$ is a subgroup of $\text{End}_F(V)$, and $V$ is an absolutely simple $H$-module; that means $V \otimes_F \overline{F}$ is a simple $\overline{F}[H]$-module where $\overline{F}$ is an algebraic closure of $F$ and $\overline{F}[H]$ is the $\overline{F}$-span of $H$ in $\text{End}_{\overline{F}}(V \otimes_F \overline{F})$. Suppose $F \subseteq E \subseteq \overline{F}$ is an intermediate subfield. Let $F[H]$ be the $F$-span of $H$ in $\text{End}_F(V) \subseteq \text{End}_E(V \otimes_F E) \subseteq \text{End}_{\overline{F}}(V \otimes_F \overline{F})$.

If $W \subseteq V \otimes_F E$ is an $F[H]$-module and $\dim_F W = \dim_F V$, then there is $\lambda \in E$ such that $W = V \otimes \lambda$. 

Proof. First we note that since $V$ is an absolutely simple $H$-module, by [26, Theorem 7.5] $F[H] = \text{End}_F(V)$; and so
\[
\text{End}_{F[H]}(V) = F. \tag{12}
\]
Suppose $\{\alpha_i\}_{i=1}^\infty$ is an $F$-basis of $E$. Then $V \otimes_F E = \bigoplus_{i=1}^\infty V \otimes \alpha_i$. For any $i$, let
\[
\text{pr}_i : W \to V \otimes \alpha_i
\]
be the projection to the $i$th summand according to this decomposition. We note that, since $l_{\alpha_i} : V \to V \otimes \alpha_i, \, l_{\alpha_i}(v) := v \otimes \alpha_i$ is an $F[H]$-module isomorphism, $V \otimes \alpha_i$ is a simple $F[H]$-module. Hence, either $\text{pr}_i(W) = 0$ or $\text{pr}_i : W \to V \otimes \alpha_i$ is a surjective $F[H]$-module homomorphism. As $\dim_F W = \dim_F V$, in the latter case $\text{pr}_i$ is an $F[H]$-module isomorphism. Let $I := \{i \in \mathbb{Z}^+ \mid \text{pr}_i(W) \neq 0\}$. Then, for $i, j \in I$,
\[
l_{\alpha_j}^{-1} \circ \text{pr}_j \circ l_{\alpha_i}^{-1} : V \to V
\]
is an $F[H]$-module isomorphism. Therefore by (12), for $i, j \in I$, there is $a_{ij} \in F^\times$ such that
\[
\text{pr}_j \circ l_{\alpha_i}^{-1}(v \otimes \alpha_i) = v \otimes a_{ij} \alpha_j. \tag{13}
\]
Since $\dim_F W = \dim_F V < \infty$, by (13) $I$ is finite. Let $i_0 \in I$; then by (13) we have
\[
W = \{ \sum_{j \in I} v \otimes a_{i_0,j} \alpha_j \mid v \in V \} = V \otimes (\sum_{j \in I} a_{i_0,j} \alpha_j);
\]
and claim follows. \qed

Proof of Proposition 23. Since $p > 5$, by [49, Lemma 4.6] $\mathfrak{h}(\overline{F}_q) / \mathfrak{z}(\overline{F}_q)$ is a simple $H$-module, where $H = [\mathbb{H}(F_q), \mathbb{H}(F_q)], \, \mathfrak{h} = \text{Lie}(H), \text{ and } \mathfrak{z}$ is the center of $\mathfrak{h}$. Hence,
\[
(\mathfrak{h}(F_q^n) + \mathfrak{z}(\overline{F}_q)) / \mathfrak{z}(\overline{F}_q) \subseteq \mathfrak{h}(\overline{F}_q) / \mathfrak{z}(\overline{F}_q)
\]
is an absolutely simple $H$-module. \tag{14}
For $g \in T(H, \mathbb{H}(F_q^n))$, $\text{Ad}(g)\mathfrak{h}(F_q^n)$ is $H$-invariant as we have $H \subseteq g\mathbb{H}(F_q^n)g^{-1}$. Since $\dim_{F_q^n} \text{Ad}(g)\mathfrak{h}(F_q^n) = \dim_{F_q^n} \mathfrak{h}(F_q^n)$, by Lemma 24 there is $\lambda(g) \in \overline{F}_q$ such that
\[
\text{Ad}(g)\mathfrak{h}(F_q^n) + \mathfrak{z}(\overline{F}_q) = \lambda(g)\mathfrak{h}(F_q^n) + \mathfrak{z}(\overline{F}_q). \tag{15}
\]
Since $p > 5$, $\mathfrak{h}(F_q^n)$ is a perfect Lie algebra. Therefore by (15), we get that for any integer $m \geq 2$ we have
\[
\text{Ad}(g)\mathfrak{h}(F_q^n) = \lambda(g)^m \mathfrak{h}(F_q^n). \tag{16}
\]
Note that $\mathfrak{h}(F_q^n)$ and $\mathfrak{h}(\overline{F}_q)$ are naturally isomorphic to $\mathfrak{h} \otimes_{F_q} F_q^n$ and $\mathfrak{h} \otimes_{\overline{F}_q} \overline{F}_q$, respectively, where $\mathfrak{h} = \mathfrak{h}(\overline{F}_q)$; and so $\lambda(g)^m \mathfrak{h}(F_q^n)$ can be identified with $\mathfrak{h} \otimes \lambda(g)^m F_q^n$. Thus, (16) implies that $\lambda(g) \in F_q^n$. Therefore, $\text{Ad}(g)\mathfrak{h}(F_q^n) = \mathfrak{h}(F_q^n)$, which means $g \in \mathbb{H}(F_q^n)$ as $\mathfrak{h}$ is of adjoint form. \qed
Corollary 25. Let $q$ be a power of a prime $p > 5$. Let $H$ be a connected, almost simple, adjoint type $\mathbb{F}_q$-group. Suppose $n$ is a positive integer and $m$ is a positive divisor of $n$. Then, for any $g \in H(\mathbb{F}_q^n) \setminus H(\mathbb{F}_q^m)$, $gH(\mathbb{F}_q^m)g^{-1} \cap H(\mathbb{F}_q^m)$ is a structural subgroup of $H(\mathbb{F}_p^n)$.

Proof. Suppose to the contrary that it is a subfield type subgroup. Then by Proposition 9 there is a subfield $F'$ of $\mathbb{F}_q^m$ and a model $\overline{H}$ of $H \otimes_{\mathbb{F}_q} \mathbb{F}_q^m$ over $F'$ such that

$$[\overline{H}(F'), \overline{H}(F')] \subseteq g\overline{H}(\mathbb{F}_q^m)g^{-1} \cap \overline{H}(\mathbb{F}_q^m) \subseteq \overline{H}(F').$$

Therefore, $g \in T([\overline{H}(F'), \overline{H}(F')], \overline{H}(\mathbb{F}_q^m))$; and so by Proposition 23 we have that $g$ is in $\overline{H}(\mathbb{F}_q^m) = H(\mathbb{F}_q^m)$, which is a contradiction. □

3 | ESCAPING FROM THE DIRECT SUM OF STRUCTURE TYPE SUBGROUPS

For a square-free polynomial $f$ (with large degree irreducible factors), we say a proper subgroup $H$ of $\pi_f(\Gamma)$ is purely structural if $\pi_f(H)$ is a structure type subgroup of $\pi_f(\Gamma) = G_\ell(K(\ell'))$ for any irreducible factor $\ell'$ of $f$. The goal of this section is to prove Proposition 6; that roughly means we show that there exists a symmetric set $\Omega' \subseteq \Gamma$ with the following property: For any square-free polynomial $f \in \mathbb{F}_q[\ell]$ with large degree irreducible factors and for any purely structural subgroup $H$ of $\pi_f(\Gamma)$, the probability that an $l \sim \deg f$-step random walk lands in $H$ is small.

3.1 | Small lifts of elements of a purely structural subgroup are in a proper algebraic subgroup

Let us recall that for any $h \in GL_{n_0}(\mathbb{F}_{q_0}[t, 1/r_0])$,

$$\|h\| := \max_{v \in D/r_0, \ell|v, i, j} |h_{ij}|_v,$$

where $h_{ij}$ is the $i,j$-entry of $h$ and $| \cdot |_\ell$ is the $\ell$-adic norm (see Section 1.4 for the definition of all the undefined symbols). For a subgroup $H$ of $\pi_f(\Gamma)$, let

$$L_\delta(H) := \{h = (h_{ij}) \in \Gamma | \pi_f(h) \in H \text{ and } \|h\| < [\pi_f(\Gamma) : H]^{\delta}\}.$$

In this section, we show that, if $H$ is purely structural, then for some $\delta \ll 1$, $L_\delta(H)$ lies in a proper algebraic subgroup of $G$. In light of Theorem 22, we follow the proof of [41, Proposition 16].

Standing assumptions. In this section, we will be working with $\Omega$, $\Gamma$, $G$, $C_\ell$, $G_\ell$, and $K(\ell')$ are as before; that means $\Gamma$ is a finitely generated subgroup of $GL_{n_0}(\mathbb{F}_{q_0}[t, 1/r_0(t)])$ where $q_0 > 7$ is a power of a prime $p > 5$ and the field generated by $\text{Tr}(\Gamma)$ is $\mathbb{F}_{q_0}(t)$, $G$ is the Zariski-closure of $\Gamma$ in $(GL_{n_0}(\mathbb{F}_{q_0}[t, 1/r_0(t)]), G$ is the generic fiber of $G$, $G$ is a connected, simply connected, absolutely almost simple group, for an irreducible polynomial $\ell', K(\ell')$ is $\mathbb{F}_{q_0}(t)/<\ell'>$, and $C_\ell$ is the fiber of $G$ over $<\ell'>$. Here $f$ denotes a square free polynomial with the property that the dichotomy mentioned in Theorem 22 holds for any of its irreducible factors. In particular, for any irreducible factor $\ell'$ of
$f$ and any proper subgroup $H_\ell$ of $\pi_\ell(\Gamma)$, we have that

$$[\pi_\ell(\Gamma) : H_\ell] \gg \Gamma \begin{cases} |K(\ell)^{\text{dim} \mathbb{G} - \text{dim} H}| \geq |K(\ell)| & \text{if } H_\ell \text{ is a structure type subgroup,} \\ |K(\ell)/F_H|^{\text{dim} \mathbb{G}} \geq |K(\ell)| & \text{if } H_\ell \text{ is a subfield type subgroup.} \end{cases}$$

This implies that

$$[\pi_\ell(\Gamma) : H_\ell] \gg \Gamma |\pi_\ell(\Gamma)|^{c_0} \quad (17)$$

for some positive number $c_0$ which depends only on $\mathbb{G}$. Moreover, we assume, if $\ell$ and $\ell'$ are two different irreducible factors of $f$, then $\deg \ell \neq \deg \ell'$. This last condition is very restrictive and in a desired result it has to be removed. Removing this condition is in the spirit of Open Problem 1.4 in [30].

We first start with approximating a proper subgroup $H$ of

$$\pi_\ell(\Gamma) \approx \bigoplus_{\ell \mid f, \ell \text{ irred.}} \pi_\ell(\Gamma) = \bigoplus_{\ell \mid f, \ell \text{ irred.}} G_\ell(K(\ell))$$

with a subgroup in product form. This is done by a variant of [41, Lemma 15].

**Lemma 26.** Suppose $\{G_i\}_{i \in I}$ is a finite collection of finite groups with the following properties.

1. $G_i = \bigoplus_{j \in J_i} L_{i,j}$ where $L_{i,j}/Z(L_{i,j})$ is simple.
2. $G_i$ is perfect; that means $G_i = [G_i, G_i]$.
3. For $i \neq j$, simple factors of $G_i/Z(G_i)$ and $G_j/Z(G_j)$ are not isomorphic.
4. There is a positive integer $c$ such that for any proper subgroup $H_i$ of $G_i$ we have $[G_i : H_i] \geq |G_i|^c$.

Then for any subgroup $H$ of $G_I := \bigoplus_{i \in I} G_i$ we have

$$\prod_{i \in I} [G_i : \text{pr}_i(H)] \geq [G_I : H]^c,$$

where $\text{pr}_i : G_I \to G_i$ is the projection to the $i$th component.

**Proof.** We proceed by strong induction on $|G_I|$. Let

$$I_1 := \{i \in I | \text{pr}_i(H) = G_i\}, \text{ and } I_2 := \{i \in I | \text{pr}_i(H) \neq G_i\}. \quad \Box$$

**Claim 1.** We can assume that $I_1 \neq \emptyset$.

**Proof of Claim 1.** If $I_1 = \emptyset$, then

$$\prod_{i \in I} [G_i : \text{pr}_i(H)] \geq \prod_{i \in I} |G_i|^c \geq |G_I|^c \geq [G_I : H]^c;$$

and claim follows. So without loss of generality, we can and will assume that $I_1 \neq \emptyset$. \quad \Box

**Claim 2.** The restriction to $H$ of the projection map $\text{pr}_{I_1}$ to $G_{I_1} := \bigoplus_{i \in I_1} G_i$ is surjective.
**Proof of Claim 1.** We proceed by induction on \(|I_1|\). The base of induction is clear. Suppose \(\text{pr}_{I'}(H) = G_{I'}\) for some subset \(I'\) of \(I\) and \(\text{pr}_i(H) = G_i\) for some \(i \in I \setminus I'\). Let \(\overline{H} := \text{pr}_{I' \cup \{i\}}(H)\). Then \(\text{pr}_i(\overline{H}) = G_i\) and \(\text{pr}_{I'}(\overline{H}) = G_{I'}\). Let \(\overline{H} := \overline{H} \cap G_i\) and \(\overline{H}(i) := \overline{H} \cap G_i\). Then projections induce isomorphisms \(\overline{H}/\overline{H}(i) \to G_i\) and \(\overline{H}/\overline{H}(i) \to G_{I'}\). Hence, we get the following commuting diagram

\[
\begin{array}{ccc}
\overline{H}/\overline{H}(i) & \cong & G_i/\overline{H}(i) \\
\cong & & \cong \\
G_i/\overline{H}(i) & \longrightarrow & G_{I'}/\overline{H}(i)
\end{array}
\] (18)

If \(\overline{H}(i)\) is a proper subgroup of \(G_i\), then \(\overline{H}(i)Z(G_i)\) is also a proper subgroup of \(G_i\); this is because \([\overline{H}(i)Z(G_i), \overline{H}(i)Z(G_i)] = [\overline{H}(i), \overline{H}(i)]\) and \(G_i\) is perfect. Therefore by (18), a simple factor of \(G_i/Z(G_i)\) is isomorphic to a simple factor of \(G_j/Z(G_j)\) for some \(j \in I'\); this contradicts our assumption. Hence, \(\overline{H}(i) = G_i\) and \(\overline{H}(I') = G_{I'}\), which implies that \(\overline{H} = G_{I' \cup \{i\}}\); and claim follows. 

**Claim 3.** \(|G : H| \leq |G_{I_2}|\) and \(\prod_{i \in I}[G_i : \text{pr}_i(H)] \geq |G_{I_2}|^c\).

**Proof of Claim 3.** Let \(H(I_2) := H \cap \ker \text{pr}_{I_1}\) where \(\text{pr}_{I_1} : G \to G_{I_1}\) is the projection to \(G_{I_1}\). Then by Claim 2, we have \(|G_{I_1}| = |H : H(I_2)|\) and so

\[
|G : H| = \frac{|G_{I_1}| |G_{I_2}|}{|G_{I_1}| |H(I_2)|} = \frac{|G_{I_2}|}{|H(I_2)|} \leq |G_{I_2}|.
\]

We also have

\[
\prod_{i \in I}[G_i : \text{pr}_i(H)] = \prod_{i \in I_2}[G_i : \text{pr}_i(H)] \geq \prod_{i \in I_2} |G_i|^c = |G_{I_2}|^c,
\]

where we have the last inequality because of our assumption and \(\text{pr}_i(H)\) being a proper subgroup of \(G_i\) for any \(i \in I_2\).

Claim 3 implies that

\[
\prod_{i \in I}[G_i : \text{pr}_i(H)] \geq |G_{I_2}|^c \geq |G : H|^c;
\]

and claim follows. 

**Proposition 27.** Under the ‘Standing assumptions’ of this section, there exists a constant \(\delta\) depending on \(\Gamma\) such that the following holds: Let \(H \leq \pi_f(\Gamma)\) be a purely structural subgroup; that means \(\pi_{\ell}(H)\) is a structural subgroup of \(\pi_{\ell}(\Gamma)\) for each irreducible factor \(\ell\) of \(f\). Then \(L_3(H)\) lies in a proper algebraic subgroup \(H\) of \(G\).

**Proof.** By Lemma 26 and (17), there exists a positive constant \(c_0\) which depends only on \(G\) such that

\[
|\pi_f(\Gamma) : \bigoplus_{\ell \in \mathcal{D}(f)} \pi_{\ell}(H)| \geq |\pi_f(\Gamma) : H|^{c_0}.
\]
If $L_{\delta} \left( \bigoplus_{\ell \in D(f)} \pi_\ell(H) \right)$ lies in a proper algebraic subgroup of $G$, then so does $L_{\delta/\epsilon_0} (H)$. Therefore, we can and will replace $H$ with $\bigoplus_{\ell \in D(f)} \pi_\ell(H)$. Similarly, after replacing $f$ with the product of those irreducible factors satisfying $\pi_\ell (H) \neq \pi_\ell (\Gamma)$, we may assume $\pi_\ell (H)$ is a proper subgroup for each irreducible factor $\ell$ of $f$. By Theorem 22, there exists a constant $d_0 := d_0(\Gamma)$ such that for any $\ell \in D(f)$, there is a polynomial of degree at most $d_0$ and $\gamma_\ell \in \Omega$ such that $f_\ell (\pi_\ell (H)) = 0$ and $f_\ell (\pi_\ell (\gamma_\ell)) = 1$.

First we show that $L_{\delta}(H)$ lies in a low complexity proper algebraic subset of $G$. To this end, we consider the degree $d_0$ monomial map

$$
\Psi : \mathbb{GL}_{n_0} \rightarrow \mathbb{A}_{d_1},
$$

where

$$
d_1 = \binom{n_0^2 + d_0}{d_0}.
$$

Let $d$ be the dimension of the linear span of $\Psi(\mathbb{G}(\mathbb{F}_{q_0}(t)))$. To show $L_{\delta}(H)$ lies in a proper algebraic subgroup of $G$, it suffices to prove that $\Psi(L_{\delta}(H))$ spans a subspace of dimension less than $d$ if $\delta$ is sufficiently small.

Suppose to the contrary that the linear span of $\Psi(L_{\delta}(H))$ is $d$ dimensional. Hence, there is a set of $d$ linearly independent elements $h_1, h_2, \ldots, h_d$ of $\Psi(L_{\delta}(H))$.

Looking at the explicit formula for the number of elements of finite simple groups of Lie type [11, Sections 11.1 and 14.4], we have $|G_\ell(K(\ell))| \leq |K(\ell)|^{\dim G} = q_0^{\dim G \cdot \deg \ell}$. Hence,

$$
\pi_f(\Gamma) \leq d_0^{\dim G \cdot \deg f}.
$$

Thus for $h \in L_{\delta}(H)$, we have

$$
\|h\| < [\pi_f(\Gamma) : H]^\delta \leq |\pi_f(\Gamma)|^\delta \leq d_0^{\delta \dim G \cdot \deg f}.
$$

This implies that the entries of the vectors $h_1, \ldots, h_d \in \mathbb{F}_{q_0}(t)^{d_1}$ are of the form $a \prod_{\ell \in D(r_0)} \ell^{e_\ell}$ with $a \in \mathbb{F}_{q_0}[t]$, $\gcd(a, \prod_{\ell \in D(r_0)} \ell^{e_\ell}) = 1$,

$$
\deg a - \sum_{\ell \in D(r_0)} e_\ell \deg \ell < d_0 \delta \dim G \cdot \deg f, \quad (19)
$$

and for each $\ell \in D(r_0)$

$$
e_\ell \deg \ell < d_0 \delta \dim G \cdot \deg f. \quad (20)
$$

By the contrary assumption, the determinant $s(t) \in \mathbb{F}_{q_0}(t)$ of a $d$-by-$d$ submatrix of the matrix $X$ that has the vectors $h_1, \ldots, h_d$ in its rows is non-zero. By (19) and (20), we have that $s(t) = \frac{a'}{\prod_{\ell \in D(r_0)} \ell^{e_\ell}}$ for some $a' \in \mathbb{F}_{q_0}[t]$ and $e_\ell \in \mathbb{Z}_{\geq 0}$ such that

$$
\deg a' \leq \delta((|D(r_0)| + 1)d_0 \dim G) \deg f \leq \delta((|D(r_0)| + 1)|D(r_0)|d_0 \dim G) \max_{\ell \in D(f)} \deg \ell.
$$
Hence for $\delta < ((|D(r_0)| + 1)|D(r_0)|d_d \dim G)^{-1}$, there is an irreducible factor $\ell_0$ of $f$ such that $\deg a' < \deg \ell_0$; in particular, $\pi_{\ell_0}(s(t)) \neq 0$. This implies that $\pi_{\ell_0}(h_1), \ldots, \pi_{\ell_0}(h_d)$ are $K(\ell_0)$-linearly independent in $K(\ell_0)^{d_d}$; and so the right kernel of $\pi_{\ell_0}(X)$ is zero. By the definition of $\mathcal{L}_\delta(H)$, we have that $\pi_{\ell_0}(h_1) \in \Psi(\pi_{\ell_0}(H))$. Since $f_{\ell_0}(\pi_{\ell_0}(H)) = 0$ and $\deg f \leq d_0$, we have that the coefficients of $f_{\ell_0}$ form a column vector in the right kernel of $\pi_{\ell_0}(X)$, which is a contradiction.

Therefore, there is a proper algebraic subset $\mathcal{X}$ of $G$ whose complexity is $O_1(1)$, and $\mathcal{L}_\delta(H)$ is a subset of $\mathcal{X}(F_{q_0}(t))$. By [15, Proposition 3.2] if $A \subseteq G(F_{q_0}(t))$ is a generating set of a Zariski-dense subgroup of $G$, then there exists a positive integer $N$ depending on the complexity of $\mathcal{X}$ such that $\prod_N A \not\subseteq \mathcal{X}(F_{q_0}(t))$. It should be pointed out that the statement of [15, Proposition 3.2] is written for algebraic varieties and groups over $\mathbb{C}$. Its proof, however, is based on a generalized Bézout theorem that has a positive characteristic counterpart (see [14, III, Theorem 2.2; 18, Example 12.3.1; 43, p. 519]). Altogether one can see that the proof of [15, Proposition 3.2] is valid over any algebraically closed field. Since

$$\prod_N \mathcal{L}_{\delta/N}(H) \subseteq \mathcal{L}_\delta(H) \subseteq \mathcal{X}(F_{q_0}(t)),$$

we deduce that the group generated by $\mathcal{L}_{\delta/N}(H)$ is not Zariski-dense in $G$; that means that $\mathcal{L}_{\delta/N}(H)$ lies in a proper algebraic subgroup of $G$; and claim follows as $N = O_1(1)$.

3.2 Invariant theoretic description of proper positive dimensional subgroups of a simple group: The positive characteristic case

In this section, we provide an invariant theoretic (or one can say a geometric) description of proper positive dimensional algebraic subgroups of an absolutely almost simple group over a field of positive characteristic. This is the positive characteristic counterpart of [41, Proposition 17, part (1)]; and later it plays an important role in the proof of Proposition 6.

In this section we slightly deviate from our ‘Standing assumptions’, and let $G$ be a simply connected absolutely almost simple algebraic group defined over a positive characteristic algebraically closed field $k$.

**Proposition 28.** Let $G$ be an absolutely almost simple group defined over an algebraically closed field $k$ of positive characteristic. Then there are finitely many group homomorphisms $\{\rho_i : G \to (GL)_{V_i}\}_{i=1}^d$ and $\{\rho'_j : G \to Aff(W_j)\}_{j=1}^{d'}$ such that

1. for any $i$, $\rho_i$ is irreducible and non-trivial;
2. for any $j$, $\rho'_j(g)(v) := \rho'_{lin,j}(g)(v) + w_j(g)$ where $\rho'_{lin,j} : G \to GL(W_j)$ is irreducible and non-trivial, and $w_j(g) \in W_j(k)$; and no point of $W_j(k)$ is fixed by $G(k)$ under the affine action given by $\rho'_j$;
3. for every positive dimensional closed subgroup $H$ of $G$, either there is an index $i$ and a non-zero vector $v \in V_i(k)$ such that $\rho_i(H(k))[v] = [v]$ where $[v]$ is the line in $V_i(k)$ spanned by $v$, or there is an index $j$ and a point $w$ in $W_j(k)$ such that $\rho'_j(H(k))(w) = w$.

Let us remark that in the characteristic zero case any affine representation $V$ of a semisimple group has a fixed point; here is a quick argument: suppose $g \cdot v := \rho(g)(v) + c(g)$. We identify the affine space of $V(k)$ with the hyperplane $\{(v,1)v \in V(k)\}$ of $W := V(k) \oplus k$; and so $\hat{\rho}(g) :=$
\((\hat{\rho}(g)c(g) \circ \rho(g)) \circ (g \cdot v,1) = \hat{\rho}(g)(v,1)\) is a group homomorphism and \((g \cdot v,1) = \hat{\rho}(g)(v,1)\). In the characteristic zero case any module is completely reducible; and so there is a line \([v]\) which is invariant under \(G(k)\) and \(W = V(k) \oplus [v]\). As \(G\) is semisimple, it does not have a non-trivial character. Hence, any point on \([v]\) is a fixed point of \(G(k)\). As \([v] \nsubseteq V(k)\), after rescaling, if needed, we can and will assume that \(v = (v_0,1)\) for some \(v_0 \in V(k)\). Therefore, \(\hat{\rho}(g)(v) = v\) implies that \(g \cdot v_0 = v_0\).

In the positive characteristic case, however, there are affine transformations of \(G(k)\) that have no fixed points: there are irreducible representations \(V\) of \(G\) such that \(H^1(G(k), V(k)) \neq 0\). Hence there is a non-trivial cocycle \(c : G(k) \to V(k)\). Since \(c\) is a cocycle, \(g \cdot v := \rho(g)(v) + c(g)\) is a group action. If \(g \cdot v_0 = v_0\) for some \(v_0\), then \(c(g) = v_0 - \rho(g)(v_0)\) which means \(c\) is a trivial cocycle; and this contradicts our assumption.

This said it is not clear to the authors if the mentioned affine representations are needed in Proposition 28 or not.

**Question 29.** Suppose \(G\) is a connected, absolutely almost simple group and \(H\) is a positive dimensional proper subgroup of \(G\). Is there a non-trivial irreducible representation \(\rho : G \to GL(V)\) of \(G\) and a non-zero vector \(v \in V(k) \setminus \{0\}\) such that \(\rho(H(k))(\langle v \rangle) = \langle v \rangle\)?

As we will see in the proof of Proposition 28, the mentioned affine representations arise as submodules of wedge powers of the adjoint representation of \(G(k)\). When the characteristic of the field \(k\) is large compared to the dimension of \(G\), all these representations are completely reducible; and so by a similar argument as in the characteristic zero case, one can see that such affine representations do not occur. Hence, one gets a positive affirmative answer to Question 29.

**Proof Proposition 28.** Since \(H\) is a proper positive dimensional subgroup, \(h := \text{Lie}(H)(k)\) is a non-trivial proper subspace of \(g := \text{Lie}(G)(k)\). Since \(G\) is an absolutely almost simple group, \(g/z\) is a simple \(G := G(k)\)-module where \(z := Z(g)\) is the center of \(g\) and \(g\) is a perfect Lie algebra; that means \(g = [g,g]\). Therefore, \((h + z)/z\) is a proper subspace of \(g/z\) and it is not \(G\)-invariant. Thus, \(h\) is not invariant under \(G\). From here we deduce that \(l_H := \Lambda^{\text{dim}_k h} g\) is not invariant under \(G\), where \(G\) acts on \(\Lambda^{\text{dim}_k h} g\) via the representation \(\Lambda^{\text{dim}_k h} \text{Ad}\). Suppose

\[
0 := V_0 \subset V_1 \subset \cdots \subset V_m := \Lambda^{\text{dim}_k h} g
\]

is a composition factor of \(\Lambda^{\text{dim}_k h} g\). Let \(m'\) be the smallest index such that \(l_H \subseteq V_{m'}\) as a \(G\)-module. Hence, \(l_H \nsubseteq V_{m'-1}\), which implies \(l_H \oplus V_{m'-1} \subseteq V_{m'}\).

**Step 1.** (Composition factor is non-trivial) If \(\text{dim}_k V_{m'}/V_{m'-1} > 1\), then \(V_{m'}/V_{m'-1}\) is a non-trivial simple \(G\)-module that has a line which is \(H\)-invariant; here \(H := H(k)\).

**Step 2.** (Triviality of the composition factor gives us an affine action whose linear part is irreducible.) If \(\text{dim}_k V_{m'}/V_{m'-1} = 1\), then \(l_H \oplus V_{m'-1} = V_{m'}\). Let \(V := V_{m'-1}/V_{m'-2} \neq 0\) and \(W := V_{m'}/V_{m'-2}\); and so \(W/V\) is a one-dimensional \(G\)-module. Since \(G\) has no non-trivial character, \(G\) acts trivially on \(W/V\). Suppose \(w \in W \setminus V\); then for any \(g \in G\), \(c_w(g) := \rho_W(g)(w) - w \in V\). For \(v \in V\) and \(g \in G\), we let \(g \cdot v := \rho_V(g)(v) + c_w(g)\); then

\[
g_1 \cdot (g_2 \cdot v) = \rho_V(g_1)((g_2 \cdot v)) + c_w(g_1)
= \rho_V(g_1)(\rho_V(g_2)(v) + c_w(g_2)) + c_w(g_1)
= \rho_V(g_1g_2)(v) + \rho_W(g_1)(\rho_W(g_2)(w) - w) + (\rho_W(g_1)(w) - w)
\]
\[\rho_V(g_1 g_2)(v) + \rho_W(g_1 g_2)(w) = \rho_V(g_1 g_2)(v) + \rho_W(g_1 g_2)(w) - w \]
\[= \rho_V(g_1 g_2)(v) + \rho_W(g_1 g_2)(w) - w \]
\[= \rho_V(g_1 g_2)(v) + (\rho_W(g_1 g_2)(w) - w) \]
\[= \rho_V(g_1 g_2)(v) + c(g_1 g_2) = (g_1 g_2) \cdot v.\]

So, \( g \cdot v \) defines an affine action of \( G \) on \( V \). Suppose \( x_H \in l_H \setminus \{ 0 \} \); then \( x_H = c_0 w + v_0 \) for some \( c_0 \in k^* \) and \( v_0 \in V \). For any \( h \in H \), we have \( \rho_W(h)(x_H) = x_H \), which implies that \( c_0(\rho_W(h)(w) - w) = v_0 - \rho_V(h)(v_0) \). Therefore, for any \( h \in H \),
\[c_w(h) = c_0^{-1}(v_0 - \rho_V(h)(v_0)).\]  
(21)

Since \( x_H \) is not fixed by \( G \), there is \( g_0 \in G \) such that \( \rho_W(g_0)(x_H) \neq x_H \), which implies
\[c_w(g_0) \neq c_0^{-1}(v_0 - \rho_V(g_0)(v_0)).\]  
(22)

**Step 3.** (Affine action has a fixed point) If the above affine action has a fixed point \( v_1 \in V \), then for any \( g \in G \),
\[v_1 = \rho_V(g)(v_1) + c_w(g).\]  
(23)

By (21) and (23), for any \( h \in H \), we have \( v_1 - \rho_V(h)(v_1) = c_0^{-1}(v_0 - \rho_V(h)(v_0)) \), which implies
\[\rho_V(h)(c_0^{-1}v_0 - v_1) = c_0^{-1}v_0 - v_1.\]  
(24)

By (22) and (23), we have \( \rho_V(g_0)(c_0^{-1}v_0 - v_1) \neq (c_0^{-1}v_0 - v_1) \). Therefore, \( \rho_V \) is a non-trivial irreducible representation of \( G \) that has a non-zero vector fixed by \( H \).

**Step 4.** (Affine action does not have a fixed point) Now suppose that the above affine action does not have a \( G \)-fixed point; then by (21) for any \( h \in H \),
\[h \cdot (c_0^{-1}v_0) = \rho_V(c_0^{-1}v_0) + c_w(h) = \rho_V(h)((c_0)^{-1}v_0)) + c_0^{-1}(v_0 - \rho_V(h)(v_0)) = c_0^{-1}v_0,\]
which means \( H \) has a fixed point; and so claim follows. \(\square\)

### 3.3 Invariant theoretic description of small lifts of purely structural subgroups

In this section based on Propositions 27 and 28, we give an invariant theoretic understanding of small lifts of purely structural subgroups of \( \pi_f(\Gamma) \) under the ‘Standing assumptions’ (see the second paragraph of Subsection 3.1).

**Proposition 30.** Let \( \Gamma, G, f \) be as in the ‘Standing assumptions’. Then

1. there are local fields \( K_i \) and \( K'_j \) that are field extensions of \( F_{q_0}(t) \);
2. there are homomorphisms \( \rho_i : G \otimes_{F_{q_0}(t)} K_i \to GL(V_i) \) and \( \rho'_j : G \otimes_{F_{q_0}(t)} K'_j \to Aff(W_j) \) such that
(a) The functions $\rho_i$ are non-trivial irreducible representations over a geometric fiber; that means after a base change to an algebraic closure of $K_i$, $\rho_i$ is non-trivial and irreducible,
(b) the linear parts $\rho_{\text{lin},j}'$ of the affine representations $\rho_j'$ are non-trivial irreducible representations over a geometric fiber,
(c) $G(K_j')$ does not fix any point of $\mathcal{W}_j(K_j')$,
(d) $\rho_i(\Gamma) \subseteq \text{GL}(V_i(\kappa_i))$ and $\rho_{\text{lin},j}'(\Gamma) \subseteq \text{GL}(\mathcal{W}_j(K_j'))$ are unbounded subgroups;
(3) there is $\delta > 0$ depending on $\Gamma$ such that for any purely structural subgroup $H$ of $\pi_f(\Gamma)$ one of the following conditions hold:
(a) the group generated by $L_\delta(H)$ is a finite subgroup of $\Gamma$,
(b) for some $i$, there is a non-zero $v \in \mathcal{V}(K_i)$ such that for any $h \in L_\delta(H)$, $\rho_i(h)(v) = v$,
(c) for some $j$, there is $w \in \mathcal{W}_j(K_j')$ such that for any $h \in L_\delta(H)$, $\rho_j'(h)(w) = w$.

Proof. Let $k$ be an algebraic closure of $\mathcal{F}_{q_0}(t)$; then by Proposition 28 the geometric fiber $\mathcal{G} := G \otimes_{\mathcal{F}_{q_0}(t)} k$ of $G$ has representations $\{\overline{\rho}_i\}_i$ and $\{\overline{\rho}_j'\}_j$ that can describe positive dimensional proper subgroups of $\mathcal{G}$ (as in the statement of Proposition 28). There is a finite Galois extension $L$ of $\mathcal{F}_{q_0}(t)$ such that $\overline{\rho}_i$ and $\overline{\rho}_j'$ have Galois descents $\widehat{\rho}_i$ and $\widehat{\rho}_j'$ to $G \otimes \mathcal{F}_{q_0}(t) L$. As $\Gamma$ is a discrete subgroup of $\prod_{v \in D(r_0) \cup \{v_\infty\}} G(K_v)$ where $K_v$ is the $v$-adic completion of $\mathcal{F}_{q_0}(t)$, for any $i$ and $j$ there are some $v_i, v'_j \in D(r_0) \cup \{v_\infty\}$ and extensions $\nu_i, \nu'_j \in V_L$ of $v_i$ and $v'_j$, respectively, such that $\widehat{\rho}_i(\Gamma) \subseteq \text{GL}(\mathcal{V}(L_{\nu_i}))$ and $\widehat{\rho}_j'(\Gamma) \subseteq \text{GL}(\mathcal{W}_j(L_{\nu'_j}))$ are unbounded. So $\mathcal{K}_i := L_{\nu_i}, \mathcal{K}_j' := L_{\nu'_j}, \rho_i := \widehat{\rho}_i \otimes \text{id}_{\mathcal{K}_i},$ and $\rho_j' := \widehat{\rho}_j' \otimes \text{id}_{\mathcal{K}_j'}$ satisfy parts (1) and (2).

Let $\delta$ be as in Proposition 27; then for any structural subgroup $H$ of $\pi_f(\Gamma)$, there is a proper subgroup $H$ of $G$ such that $L_\delta(H) \subseteq H(k)$. If $H$ is zero-dimensional, then the group generated by $L_\delta(H)$ is a finite group. If $H$ is positive dimensional, then Proposition 28 implies that either $(3b)$ holds or $(3c)$; and claim follows. □

### 3.4 Ping-pong argument

Let us recall that under the ‘Standing assumptions’ (see the second paragraph of Subsection 3.1), we want to show a random walk with respect to the probability counting measure on $\pi_f(\Omega)$ after $O(\deg f)$-many steps lands in a purely structural subgroup $H$ of $\pi_f(\Gamma)$ with small probability. Considering the lift of this random walk in $\Gamma$, we have to say that after $O(\delta_0 \deg f)$-many steps, the probability of landing in $L_\delta(\Omega)$ is small. By Proposition 30, it is enough to make sure that the probability of landing in a proper algebraic subgroup of $G$ is small. In this section, we point out that the characteristic of the involved fields are irrelevant in the ping-pong type argument in [41, Subsection 3.2], and we get similar statements in the global function field case. After having the needed ping-pong players, using Proposition 28 we end up getting a finite symmetric subset $\Omega_0$ such that a random walk with respect to the probability counting measure on $\Omega_0$ has an exponentially small chance of landing in a proper algebraic subgroup of $G$. In this note, we do not repeat any of the proofs presented in [41, 48], and we refer the readers to those articles for the details of the arguments.

For a subset $\Omega'$ of a group and a positive integer $l$, we let

$$B_l(\Omega') := \{g_1 \cdots g_l | g_i \in \Omega' \cup \Omega'^{-1}, g_i \neq g_{i+1}^{-1}\};$$

so the support of the $l$-step random walk with respect to the probability counting measure on $\Omega' \cup \Omega'^{-1}$ is $\bigcup_{2k \leq l} B_{l-2k}(\Omega')$. 

**Proposition 31.** Let $\Gamma, \mathcal{G}$ be as in the ‘Standing assumptions’. Let $\mathcal{K}, \mathcal{K}', \rho, \rho'$ be as in Proposition 30. Then there exists a finite subset $\Omega' \subset \Gamma$ that freely generates a subgroup $\Gamma'$ with the following properties.

1. For any $i$ and any non-zero vector $v \in \mathcal{V}_i(\mathcal{K}_i)$,
   \[|\{ g \in B_c(\Omega')|\rho_i(g)([v]) = [v]\}| < |B_c(\Omega')|^{1-c'}.
   \]

2. For any $j$ and any point $w \in \mathcal{W}_j(\mathcal{K}'_j)$
   \[|\{ g \in B_c(\Omega')|\rho'_j(g)(w) = w\}| < |B_c(\Omega')|^{1-c'},
   \]
   where $c'$ is a constant depending only on $\Omega'$ and the representations.

**Proof.** See proof of [41, Proposition 20]. \(\square\)

### 3.5 Escaping purely structural subgroups: Finishing proof of Proposition 6

This proof is almost identical to the proof of [41, Proposition 7]. Let $\Gamma, \mathcal{G}, \mathcal{G}_0, \mathcal{K}_0$ be as in the ‘Standing assumptions’. Let $\Omega'$ be the set given by Proposition 31. Suppose $H \subseteq \pi_f(\Gamma)$ is a purely structural subgroup. Let $\delta$ be as in Proposition 30.

As $\pi_f[\mathcal{P}_{\Omega'}][l](H)^2 \leq \pi_f[\mathcal{P}_{\Omega'}][2l](H)$, it is enough to prove the claim for even positive integers $l$. We note that for any positive integer $l$

\[\pi_f[\mathcal{P}_{\Omega'}][2l](H) = \mathcal{P}_{\Omega'}^{(2l)} \left( \bigcup_{0 \leq k \leq l} (\pi_f^{-1}(H) \cap B_{2l-2k}(\Omega')) \right);
\]

and for any $\gamma \in \pi_f^{-1}(H) \cap B_l(\Omega')$, $\|\gamma\| \leq (\max_{w \in \Omega'} \|w\|)^l$. Hence for $l \ll \Omega', \delta \log[\pi_f(\Gamma) : H]$ and $\deg f \gg \Omega' 1$, we have

\[\mathcal{P}_{\pi_f(\Omega')}[l](H) \leq \sum_{0 \leq k \leq l} \mathcal{P}_{\Omega'}^{(2l)}(\mathcal{L}_{\delta}(H) \cap B_{2l-2k}(\Omega')). \tag{25}\]

We note that, since $\Omega' = \Omega'_0 \cup \Omega'_{-1}$ and $\Omega'_0$ freely generates a subgroup, for $\gamma, \gamma' \in B_{2r}(\Omega')$ we have $\mathcal{P}_{\Omega'}^{(2l)}(\gamma) = \mathcal{P}_{\Omega'}^{(2l)}(\gamma')$; let $P_l(r) := \mathcal{P}_{\Omega'}^{(2l)}(\gamma)$ for some $\gamma \in B_{2r}(\Omega')$. Hence by (25), we have

\[\mathcal{P}_{\pi_f(\Omega')}[l](H) \leq \sum_{0 \leq r \leq l} \mathcal{L}_{\delta}(H) \cap B_{2r}(\Omega')|P_l(r). \tag{26}\]

Combining Propositions 30 and 31, we have

\[|\mathcal{L}_{\delta}(H) \cap B_{2r}(\Omega')| < |B_{2r}(\Omega')|^{1-c'},\tag{27}\]

where $c'$ is the constant from Proposition 31.
Let us recall a few well-known results related to random walks (in a free group); for any $\gamma \in \langle \Omega' \rangle$, by Cauchy–Schwarz inequality, we have

$$P^{(2)}_{\Omega'}(\gamma) = \sum_{\gamma'} P^{(l)}_{\Omega'}(\gamma')P^{(l)}_{\Omega'}(\gamma'^{-1}) \leq \|P^{(l)}_{\Omega'}\|^2 = \sum_{\gamma'} P^{(l)}_{\Omega'}(\gamma')P^{(l)}_{\Omega'}(\gamma'^{-1}) = P^{(2)}_{\Omega'}(I),$$

where $I$ is the identity matrix; and so $P_l(r) \leq P_l(0)$ for any non-negative integer $r$. Since $P_{l_1}(0)P_{l_2}(0) \leq P_{l_1+l_2}(0)$, we have that $\{\sqrt{P_l(0)}\}$ is a non-decreasing sequence. Hence by Kesten’s result [24, Theorem 3], we have

$$P_l(r) \leq P_l(0) \leq (\frac{2M - 1}{M^2})^l,$$

where $|\Omega'| = 2M$. We also have $|B_{2r}(\Omega')| = 2M(2M - 1)^{2r-1}$. Therefore by (25), (27), and (29), for $l = \Theta |\Omega'|([\pi_f(\Gamma) : H])$, we have

$$P^{(2l)}_{\pi_f(\Omega')}(H) \leq \sum_{0 \leq r \leq l/20} |\mathcal{L}_{\delta}(H) \cap B_{2r}(\Omega')|P_l(0) + \sum_{l/20 < r \leq l} |\mathcal{L}_{\delta}(H) \cap B_{2r}(\Omega')|P_l(r)$$

$$\leq \left(1 + 2M \sum_{1 \leq r \leq l/20} (2M - 1)^{2r-1}\right) \left(\frac{2M - 1}{M^2}\right)^l + \sum_{l/20 < r \leq l} |B_{2r}(\Omega')|^{1-\epsilon}P_l(r)$$

$$\leq \left(\frac{2M}{M^2}\right)^{11l/10 + 1} + \left(\frac{2M(2M - 1)^{1/10}}{M^2}\right)^l\sum_{l/20 < r \leq l} |B_{2r}(\Omega')|P_l(r)$$

for any $g \in \pi_f(\Gamma)$. Hence for any $l' > l$, we have

$$P^{(l')}_{\pi_f(\Omega')}(gH)^2 \leq P^{(2l')}_{\pi_f(\Omega')}(H) \leq [\pi_f(\Gamma) : H]^{-\delta_0}.$$
divisor of deg $\ell$ that is at most $\max(\deg s, \deg r)$. So, if all the prime divisors of deg $\ell$ are more than $c_0 := \max(\deg s, \deg r)$, then

$$F_p[s(t)/r(t)]/\langle \ell' \rangle = F_p[t]/\langle \ell' \rangle;$$

and claim follows.

4  |  A VARIATION OF VARJÚ’s PRODUCT THEOREM

In [48], Varjú introduced a technique on proving a multi-scale product result for the direct product of an infinite family of certain finite groups. He provided a series of conditions for each one of the factors for this gluing process to work. One of the important conditions is on the structure of the subgroups of each factor; it was assumed that subgroups can be divided into $O(1)$ families of different dimensions. This condition was modeled from Nori’s theorem on description of subgroups of $GL_n(F_p)$, which roughly says that any such subgroup is very close to being the $F_p$-points of an algebraic subgroup. As we discussed in Section 2, subgroups of $GL_n(F_{p^m})$ might be either structural or subfield type; and the subfield type subgroups cannot be grouped into an $O_n(1)$ family of subgroups. We, however, use the fact that intersection of two conjugate subgroups of subfield type is a structural subgroup (see Corollary 25), and modify Varjú’s axioms and arguments accordingly (see Proposition 33).

Most of Varjú’s arguments and results stay the same even after the modifications of the assumptions; but we reproduce some of those arguments. It should be pointed out that there is an error in the proof of [48, Corollary 14]. Our modified axioms help us to resolve this issue; Varjú has also communicated to us a way to correct the proof without changing the original assumptions.

4.1  |  Modified assumptions

Before stating our modified assumptions, let us introduce a notation and recall the definition of quasi-random groups (this concept was introduced by Gowers [16]). For two subgroups $H$ and $H'$ of a finite group $G$ and a positive integer $L$, we write $H \preceq_L H'$ if $[H : H' \cap H] < L$.

**Definition 32.** For a positive constant $c$, we say a finite group $G$ is $c$-quasi-random if for any non-trivial irreducible representation $\rho$ of $G$ we have $\dim \rho > |G|^c$.

Our set of axioms depend on two parameters $L$ and $\delta_0$, where $L$ is a positive integer and $\delta_0 : \mathbb{R}^+ \to \mathbb{R}^+$ is a function.

**Assumptions (V1)$_L$ –(V3)$_L$ and (V4)$_{\delta_0}$**

(V1)$_L$  $G$ is an almost simple group with $|Z(G)| < L$.

(V2)$_L$  $G$ is $L^{-1}$-quasi-random (see Definition 32).

(V3)$_L$  There exists an integer $m < L$, and classes of proper subgroups $H_j$ for $1 \leq j \leq m$ and $H'_i$ for $1 \leq i \leq m'$ where $m' \leq L \log |G|$ with the following properties.

(i) For each $i$, $H_i$ and $H'_i$ are closed under conjugation by elements in $G$.

(ii) $H_0 = \{Z(G)\}$.

(iii) For each proper subgroup $H$ of $G$, there exist an index $i$ and a subgroup $H^3 \in H_i$ or $H'_i$ such that $H \preceq_L H^3$. 
(iv) For each \( i \) and for each pair of distinct subgroups \( H_1, H_2 \in \mathcal{H}_i \), there exists \( j < i \) and a subgroup \( H^j \in \mathcal{H}_j \) such that \( H_1 \cap H_2 \trianglelefteq L H^j \). For any \( H \in \mathcal{H}_i \), there is \( j \) and \( H^j \in \mathcal{H}_j \) such that \( N_G(H) \trianglelefteq L H^j \).

(v) For each \( i \) and for each pair of distinct subgroups \( H'_1, H'_2 \in \mathcal{H}'_i \), there exists \( j \) and a subgroup \( H^j \in \mathcal{H}_j \) such that \( H'_1 \cap H'_2 \trianglelefteq L H^j \). For any \( H \in \mathcal{H}'_i \), there is \( j \) and \( H^j \in \mathcal{H}_j \) such that \( N_G(H) \trianglelefteq L H^j \).

\( \delta_0 \) If \( S \subseteq G \) is a generating set and \( |S| < |G|^{1-\varepsilon} \) for a positive number \( \varepsilon \), then \( |S \cdot S \cdot S| > |S|^{1+\delta_0(\varepsilon)} \).

**Proposition 33.** For \( L \in \mathbb{Z}^+ \), \( \delta_0 : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \), suppose \( \{G_i\}_{i=1}^{\infty} \) is a family of pairwise non-isomorphic finite groups that satisfy assumptions (VI)_L−(V3)_L and (V4)_{\delta_0}. Then for any \( \varepsilon > 0 \), there is \( \delta > 0 \) such that for any \( n \in \mathbb{Z}^+ \) and any symmetric subset \( S \) of \( G := \bigoplus_{i=1}^{n} G_i \) satisfying

\[
|S| < |G|^{1-\varepsilon} \text{ and } \mathcal{P}_S(gH) < [G : H]^{-\varepsilon} |G|^\delta \text{ for any subgroup } H \text{ of } G \text{ and } g \in G,
\]

we have

\[
|\Pi_3 S| \gg \varepsilon |S|^{1+\delta}.
\]

Let us reiterate that there are two key differences between Proposition 33 and [48, Proposition 14]: (1) In Varjú’s setting, we have only \( O(L) \) families of proper subgroups, and this parameter resembles dimension of an algebraic subgroup. In our setting, however, we have two types of families of proper subgroups, and only one of the types can have at most \( O(L) \) families of proper subgroups. These types resemble the structural and the subfield type subgroups. For the structural subgroups we more or less use dimension of the underlying algebraic groups to parameterize them, and for subfield type subgroups the order of the subfield gives us the needed parameterization. It is clear that in this case the number of such possible families can grow as \( |G| \) goes to infinity; but it does not get more than \( \log |G| \). (2) We are assuming a product type result for each factor (see (V4)_{\delta_0}) instead of an \( l^2 \)-flattening assumption for measures with large \( l^2 \)-norm (see (A4) in [48, Section 3]). This modification helps us resolve the mentioned error in [48, Corollary 14].

### 4.2 A detailed overview of Varjú’s proof

Before getting to the multi-scale setting of Proposition 33, we recall Bourgain–Gamburd’s result which gives us a way to measure how product of two random variables gets *substantially more random* unless there is an algebraic obstruction (see [2, Proposition 2; 48, Lemma 15]).

**Lemma 34.** Let \( \mu \) and \( \nu \) be two probability measures on an arbitrary finite group \( G \), and let \( K \) be a real number greater than 2. If \( \|\mu \ast \nu\|_2 > \frac{1}{K} \|\mu\|_2^{1/2} \|\nu\|_2^{1/2} \), then there is a symmetric subset \( A \subseteq G \) with the following properties:

1. (Size of \( A \) is comparable with \( \|\mu\|_2^{-2} \)) \( K^{-R} \|\mu\|_2^{-2} \leq |A| \leq K^R \|\mu\|_2^{-2} \).
2. (An approximate subgroup) \( |A \cdot A \cdot A| \leq K^R |A| \).
3. (Almost equidistribution on \( A \)) \( \min_{a \in A} (\overline{\mu} \ast \mu)(a) \geq K^{-R} |A|^{-1} \),

where \( R \) is a universal constant and \( \overline{\mu}(g) := \mu(g^{-1}) \).
One can use various forms of entropy to quantify how random a measure is.

**Definition 35.** Suppose $X$ is a random variable on a finite set $S$ and has distribution $\mu$; then the (Shannon) entropy of $X$ is

$$H(X) := \sum_{s \in S} -\log(\mathbb{P}(X = s))\mathbb{P}(X = s),$$

where $\mathbb{P}(X = s)$ is the probability of having $X = s$. The Rényi entropy of $X$ is

$$H_2(X) := -\log \left( \sum_{s \in S} \mathbb{P}(X = s)^2 \right) = -\log \| \mu \|^2_2.$$

We let $H_\infty(X) := -\log(\max_{s \in \text{supp}(X)} \mathbb{P}(X = s))$ and $H_0(X) := \log |\text{supp}(X)|$, where $\text{supp}(X)$ is the support of $X$.

Suppose $Y$ is another random variable on $S$. Then the entropy of $X$ conditioned to $Y$ is

$$H(X|Y) := \sum_{y \in S} \mathbb{P}(Y = y)H(X|Y = y)$$

$$= -\sum_{y \in S} \mathbb{P}(Y = y) \sum_{x \in S} \mathbb{P}(X = x|Y = y) \log \mathbb{P}(X = x|Y = y),$$

(31)

where $X|Y = y$ is the random variable $X$ conditioned to the random variable $Y$ taking a certain value $y$, and $\mathbb{P}(X = x|Y = y)$ is the probability of having $X = x$ conditioned to $Y = y$. The Rényi entropy of $X$ conditioned to $Y$ is

$$H_2(X|Y) := \sum_{y \in S} \mathbb{P}(Y = y)H_2(X|Y = y).$$

Here are some of the basic properties of entropy that will be used in this note.

**Lemma 36.** Suppose $S$ is a finite set, and $X$ and $Y$ are random variables with values in $S$. Then

1. $H(X,Y) = H(X) + H(Y|X)$,
2. $H(X) \geq H(X|Y)$,
3. $H_0(X) \geq H(X) \geq H_2(X) \geq H_\infty(X)$,
4. $H(X|f(Y)) \geq H(X|Y)$, where $f$ is a function.

**Proof.** These are all well-known facts; for instance, see [13, Theorems 2.4.1, 2.5.1, and 2.6.4, Lemma 2.10.1, Problem 2.1].

It is very intuitive to say that the product of two independent random variables with values in a group should be at least as random as the initial random variables. The next lemma says that this intuition is compatible with how various types of entropy measure the randomness of a distribution.

**Lemma 37.** Suppose $X$ and $Y$ are two independent random variables with values in a group $G$ and finite supports. Then $H(XY) \geq \max(H_i(X), H_i(Y))$ for $i \in \{0, 1, 2, \infty\}$ where $H_1(X) := H(X)$. 

Proof. Note that \( \text{supp}(XY) = \text{supp}(X)\text{supp}(Y) \); and so \( H_0(XY) \geq \max(H_0(X), H_0(Y)) \).

For any \( g \in G \), we have
\[
P(XY = g) = \sum_{x \in G} P(X = x)P(Y = x^{-1}g) \leq \max_{y \in G} P(Y = y);
\]
and so \( H_{\infty}(XY) \geq H_{\infty}(Y) \). By symmetry we get the claim for \( i = \infty \).

Since the function \( x^2 \) is a convex function, we have
\[
P(XY = g)^2 = \left( \sum_{x \in H} P(X = x)P(Y = x^{-1}g) \right)^2 \leq \sum_{x \in G} P(X = x)P(Y = x^{-1}g)^2.
\]
Therefore, \( \sum_{g \in G} P(XY = g)^2 \leq \sum_{g \in G} \sum_{x \in G} P(X = x)P(Y = x^{-1}g)^2 = \sum_{y \in G} P(Y = y)^2 \), which implies the claim for \( i = 2 \).

By Lemma 36, we have
\[
H(XY) \geq H(X|Y) = H(X) = H(X);
\]
and claim follows.

Lemma 34 says how much the Rényi entropy of product of two independent variables increases unless there is an algebraic obstruction: if \( X \) and \( Y \) are two independent random variables with values in a group \( G \), then we have
\[
H_2(XY) \geq \frac{H_2(X) + H_2(Y)}{2} + \log K,
\] (32)
unless there is a symmetric subset \( A \) of \( G \) such that
\[
|\log |A| - H_2(X)| \leq R \log K, \quad |A \cdot A \cdot A| \leq K^R |A|,
\]
and for any \( a \in A \)
\[
P(X^{-1}X = a) \geq K^{-R} |A|^{-1},
\]
where \( X' \) is a random variable with identical distribution as \( X \) and it is independent of \( X \). Based on this result one can prove a meaningful increase in the Rényi entropy of product of two independent random variables with a Diophantine \( \text{type} \) condition with values in a group that has a \text{product type} property (similar to the condition \((V4)_{\delta_0}\)).

**Definition 38.** Suppose \( G \) is a finite group and \( X \) is a random variable with values in \( G \). We say \( X \) is of \((\alpha, \beta)-\text{Diophantine type}\) if for any proper subgroup \( H \) of \( G \) with \( |H| \geq |G|^{\alpha} \) and for any \( g \in G \), we have \( P(X \in gH) \leq [G : H]^{-\beta} \).
Lemma 39. Suppose $G$ is a finite group and $X$ and $Y$ are two independent random variables with values in $G$. Suppose $G$ satisfies the following properties.

(1) (Quasi-randomness) It is an $L^{-1}$-quasi-random group for some positive integer $L$.
(2) (Product property) For every positive number $\varepsilon$, there is a positive number $\delta_0 := \delta_0(\varepsilon)$ such that if $A$ is a generating set of $G$ and $|A| < |G|^{1-\varepsilon}$, then $|A \cdot A \cdot A| \geq |A|^{1+\delta_0}$.

Suppose the random variable $X$ satisfies the following properties.

(1) (Diophantine condition) For some $\alpha, \beta > 0$, $X$ is of $(\alpha, \beta)$-Diophantine type.
(2) (Initial entropy) $\alpha' \log |G| \leq H_2(X)$ for some $\alpha' > 2\alpha$.
(3) (Room for improvement) $H_2(X) \leq (1 - \alpha'') \log |G|$ for some $\alpha'' > 0$.

Then

$$H_2(XY) \geq \frac{H_2(X) + H_2(Y)}{2} + \gamma_0 \log |G|,$$

where $\gamma_0$ is a positive constant that only depends on $\alpha', \alpha'', \beta$, and the function $\delta_0$.

Proof. Suppose $H_2(X) < \frac{H_2(X) + H_2(Y)}{2} + \gamma \log |G|$ for some $\gamma > 0$; then by Bourgain–Gamburd’s result and the above discussion there is a symmetric subset $A$ of $G$ such that

$$|\log |A| - H_2(X)| \leq R\gamma \log |G| \quad \text{(Controlling the order),} \quad (33)$$

$$|A \cdot A \cdot A| \leq |G|^{R\gamma} |A| \quad \text{(Almost subgroup),} \quad (34)$$

$$\forall a \in A, \mathbb{P}(X'^{-1}X = a) \geq |G|^{-R\gamma} |A|^{-1} \quad \text{(Almost equidistribution),} \quad (35)$$

where $X'$ is a random variable with identical distribution as $X$ and it is independent of $X$ and $R$ is an absolute positive constant. Let $H$ be the group generated by $A$. Note that

$$\mathbb{P}(X'^{-1}X \in H) = \sum_{g \in G} \mathbb{P}(X'^{-1} \in H, g^{-1}) \mathbb{P}(X \in gH) \leq \max_{g \in G} \mathbb{P}(X \in gH). \quad (36)$$

Hence, by (36) and (35)

$$\max_{g \in G} \mathbb{P}(X \in gH) \geq \mathbb{P}(X'^{-1}X \in H) \geq \mathbb{P}(X'^{-1}X \in A) \geq |G|^{-R\gamma}, \quad (37)$$

and by the lower bound on the Rényi entropy of $X$

$$|H| \geq |A| \geq |G|^{-R\gamma} e^{H_2(X)} \geq |G|^{\alpha'/2} \quad (38)$$

for $\gamma \leq \frac{\alpha'}{2R}$. Since $X$ is of $(\alpha, \beta)$-Diophantine type and $\alpha' > 2\alpha$, by (38) and (37) we get

$$[G : H]^{-\beta} \geq \max_{g \in G} \mathbb{P}(X \in gH) \geq |G|^{-R\gamma}. \quad (39)$$
Since $G$ is an $L^{-1}$-quasi-random group, we have $[G : H] \geq |G|^{1/L}$ if $H$ is a proper subgroup; and so by (39) we get

$$\gamma \geq \frac{\beta}{RL}.$$ 

Therefore for $\gamma \leq \frac{\beta}{4RL}$, we have $G = H$, which means $A$ is a generating set of $G$.

By the upper bound on the Rényi entropy of $X$ and (33), we have

$$|A| \leq |G|^{1-\alpha''} |G|^{R\gamma} \leq |G|^{1-\frac{\alpha''}{2}}$$

for $\gamma \leq \frac{\alpha''}{2R}$. Hence, by the product property of $G$ there is $\delta_0 := \delta_0(\alpha''/2)$ such that

$$|A \cdot A \cdot A| \geq |A|^{1+\delta_0}. \quad (40)$$

By (34) and (40), we deduce

$$|G|^{R\gamma} \geq |A|^\delta_0;$$

together with (33) and the lower bound on the Réy entropy of $X$ we get

$$|G|^{R\gamma} \geq |A|^\delta_0 \geq (|G|^{-R\gamma} e^{H_2(X)})^{\delta_0} \geq |G|^{\alpha'\delta_0/2}.$$ 

Hence, we deduce that for $\gamma = \gamma_0 := \min\left(\frac{\alpha'\delta_0(\alpha''/2)}{4R}, \frac{\beta}{4RL}\right)$, we have

$$H_2(XY) \geq \frac{H_2(X) + H_2(Y)}{2} + \gamma \log |G|;$$

and claim follows. \hfill \Box

Now suppose the functions $X_j := (X_j^{(i)})_{i=1}^n$ are independent and identically distributed random variables with values in $G := \bigoplus_{i=1}^n G_i$ and distribution $P_A$. We note that (see Lemma 36)

$$\log |\prod_i A| = H_0(X_1 \cdots X_l) \geq H(X_1 \cdots X_l);$$

and by the mentioned basic properties of entropy (see Lemma 36) we have

$$H(X_1 \cdots X_l) = \sum_{j=1}^n H(X_1^{(j)} \cdots X_l^{(j)} | X_1^{(1)} \cdots X_l^{(1)}, \ldots, X_1^{(j-1)} \cdots X_l^{(j-1)})$$

$$\geq \sum_{j=1}^n H(X_1^{(j)} \cdots X_l^{(j)} | X_1^{(k)}, 1 \leq i \leq l, 1 \leq k \leq j - 1)$$

$$\geq \sum_{j=1}^n H_2(X_1^{(j)} \cdots X_l^{(j)} | X_1^{(k)}, 1 \leq i \leq l, 1 \leq k \leq j - 1).$$
At this point we are almost at the setting of Bourgain–Gamburd’s result, and we would like to apply Lemma 39. By (V2)_L and (V4)_δ₀, G_j does satisfy the conditions of Lemma 39; but the random variables X_j^{(i)} do not necessarily satisfy the required conditions. Here are the steps that we take to get the desired conditions:

**Step 1.** By a regularization argument, we find a subset A of S such that

(a) for any (g_1, ..., g_{j-1}) ∈ ⨁_{k=1}^{j-1} G_k the conditional random variables X_i^{(j)}|X_i^{(k)} = g_k, 1 ≤ k ≤ j - 1 are uniformly distributed in their support;
(b) H(X_i^{(j)}|X_i^{(k)} = g_k, 1 ≤ k ≤ j - 1) is the same for any (g_1, ..., g_{j-1}) ∈ pr_{[1..j-1]}(A) where pr_i : ⨁_{k=1}^n G_k → ⨁_{k∈I} G_k is the projection map;
(c) (Initial entropy) For any (g_1, ..., g_{j-1}) ∈ pr_{[1..j-1]}(A), either H(X_i^{(j)}|X_i^{(k)} = g_k, 1 ≤ k ≤ j - 1) = 0 or H(X_i^{(j)}|X_i^{(k)} = g_k, 1 ≤ k ≤ j - 1) ≥ α log |G_j|; (d) log |A| > log |S| - 2α log |G|.

This process (more or less) gives us the initial entropy condition.

**Step 2.** At this step, we focus on the scales where the entropy is already large and does not have much room for improvement. In the influential work [16] where Gowers defined quasi-random groups, he proved the following result (see [16, Theorem 3.3] and also [34, Corollary 1]).

**Theorem 40.** Suppose G is an L^{-1}-quasi-random group. Suppose X_1, X_2, X_3 are three independent random variables with values in G. If

$$\frac{H_0(X_1) + H_0(X_2) + H_0(X_3)}{3} > (1 - \frac{1}{3L}) \log |G|,$$

then H_0(X_1X_2X_3) = \log |G|.

We apply Theorem 40 for the conditional random variables X_i^{(j)}|X_i^{(k)} = g_i^{(k)}, 1 ≤ k ≤ j - 1 for (g_i^{(1)}, ..., g_i^{(j-1)}) ∈ pr_{[1..j-1]}(A) and at the scales where

$$H(X_i^{(j)}|X_i^{(k)} = g_i^{(k)}, 1 ≤ k ≤ j - 1) ≥ (1 - \frac{1}{3L}) \log |G|, \tag{41}$$

and deduce that ⨁_{i∈I_1} G_i = pr_{I_1}(A \cdot A \cdot A) where I_1 consists of the functions j such that (41) holds. Next we let I_s := [1..n] \setminus I_1; and define the following metric on ⨁_{i∈I_s} G_i

$$d(g, g') := \sum_{i∈I_s, pr_i(g)≠pr_i(g')} \log |G_i|.$$

Let T := max{d(g, 1) | g ∈ pr_{I_s}(Π_{S∩{1}} G_i)} Then one gets a T-almost group homomorphism ψ : ⨁_{i∈I_s} G_i → ⨁_{i∈I_s} G_i. By a result of Farah [17] on approximate homomorphisms, ψ should be close to a group homomorphism. Based on this and certain Diophantine property of S, one can deduce that

$$\exists (1, g_0) ∈ Π_{S∩{1}} G_i, d(g_0, 1) ≫ ε^2 \log |G|.$$

Now considering H := C_G((g_0, 1)) and using the assumed upper bound of P_S(gH), one gets a strong lower bound for |Π_{1..4} S| unless almost all the scales do have room for improvement.
**Step 3.** At this step, we focus on the scales where there is an initial entropy and room for improvement as required in Lemma 39. The last condition that is needed is a Diophantine type condition. Varjú (essentially) proves the following result in order to deal with this issue.

**Proposition 41.** Suppose $L$ is a positive integer, $G$ is a finite group that satisfies properties $(V1)_L$–$(V3)_L$. Let $m$ be as in $(V3)_L$. Suppose $X_1,\ldots,X_{2m+1}$ are independent random variables with values in $G$ and $H_{\infty}(X_i) \geq \alpha' \log |G|$ for some positive number $\alpha'$ and any index $i$. For $\vec{y} := (y_1,\ldots,y_{2m+1-1}) \in \bigoplus_{i=1}^{2m+1-1} G$, let $X_{\vec{y}} := X_1y_1X_2y_2\cdots y_{2m+1-1}X_{2m+1}$. Suppose $Y_1,\ldots,Y_{2m+1-1}$ are independent and identically distributed random variables with values in $G$. The functions $Y_i$ are of $(\alpha,\beta)$-Diophantine type for some positive numbers $\alpha$ and $\beta$ such that $\beta \geq 4\alpha$; further, assume that for any $g \in G$ and $H \in \bigcup_{i=1}^m H_i$, $\mathbb{P}(Y_1 \in gH) \leq [G: H]^{-\beta}$. Then assuming $|G| \gg \alpha',\beta,L,1$, we have

$$\mathbb{P}((Y_1,\ldots,Y_{2m+1-1}) = \vec{y} \text{ such that } X_{\vec{y}} \text{ is not of } (0,\beta'/2)-\text{Diophantine type}) \leq |G|^{-\frac{\beta}{4L}}$$

where $\beta' := \frac{1}{8^{m+1}} \min(\beta,\frac{\alpha'}{SL},\frac{\alpha'}{2})$.

Using Proposition 41 and Lemmas 37–39, one gets the following result.

**Proposition 42.** Suppose $L$ is a positive integer and $\delta_0 : \mathbb{R}^+ \to \mathbb{R}^+$ is a function. Suppose $G$ satisfies conditions $(V1)_L$–$(V3)_L$ and $(V4)_{\delta_0}$. Let $m$ be as in the condition $(V3)_L$. Suppose random variables $X_1,\ldots,X_{2m+1+1}$ satisfy the following properties.

1. (Initial entropy) $\alpha' \log |G| \leq H_{\infty}(X_i)$ for some $\alpha' > 0$ and any index $i$.
2. (Room for improvement) $H_2(X_i) \leq (1 - \alpha'') \log |G|$ for some $\alpha'' > 0$.

Suppose the independent and identically distributed random variables $Y_1,\ldots,Y_{2m+1-1}$ satisfy the following property.

(Diophantine condition) For some $0 \leq \alpha < \min(\beta/4,\alpha'/2)$, $Y_1$ is of $(\alpha,\beta)$-Diophantine type; and for any $H \in \bigcup_{i=1}^m H_i$ and $g \in G$, $\mathbb{P}(Y_1 \in gH) \leq [G: H]^{-\beta}$.

Then assuming $|G| \gg \alpha',\alpha'',\beta,L,\delta_0,1$, we have

$$H_2(X_1Y_1X_2\cdots Y_{2m+1-1}X_{2m+1}X_{2m+1+1}|Y_1,\ldots,Y_{2m+1-1}) \geq \min_i H_2(X_i) + \gamma \log |G|,$$

where $\gamma$ is a positive constant that only depends on $\alpha',\alpha'',\beta,L, and the function $\delta_0$.

Finally Varjú finds a subset $B$ of $S$ such that, if $Y = (Y^{(1)},\ldots,Y^{(n)})$ is a random variable with distribution $\mathcal{P}_B$, then for lots of $i$ $Y^{(i)}$ is of $(0,\varepsilon')$-Diophantine type where $\varepsilon' \gg \varepsilon,L 1$ ($\varepsilon$ and $L$ are given in Proposition 33); overall one gets

$$\log |\prod_{m+2} S| - \log |S| \gg \varepsilon,L \log |S|.$$ 

One can finish the proof of Proposition 33 using [19, Lemma 2.2] which says

$$(k - 2)(\log |\prod_{3} S| - \log |S|) \gg \log |\prod_{k} S| - \log |S|$$

for any integer $k \geq 3$. 
4.3 Regularization and a needed inequality

Let $L$, $\delta_0$, and $\{G_i\}_{i=1}^{\infty}$ be as in the statement of Proposition 33. Since the functions $G_i$ are pairwise non-isomorphic, $\lim_{i \to \infty} |G_i| = \infty$.

**Lemma 43.** Suppose $m : \mathbb{R}^+ \to \mathbb{Z}^+$ is a function. If the claim of Proposition 33 holds for $\varepsilon, \delta(\varepsilon)$, and the subfamily $\{G_i | 1 < i, |G_i| > m(\varepsilon)\}$, then Proposition 33 holds with $\delta(\varepsilon)/2$ for $\delta$ and a possibly larger implied constant in the final claimed inequality.

Let us remark that $\delta$ also depends on $L$ and $\delta_0$; but we are assuming that those are fixed in the entire section.

**Proof of Lemma 43.** Suppose $S$ is a symmetric subset of $G := \bigoplus_{i=1}^{n} G_i$ such that

$$|S| < |G|^{1-\varepsilon} \text{ and } P_S(gH) < [G : H]^{-\varepsilon}|G|^{\delta(\varepsilon)/2}$$

(42)

for any subgroup $H$ of $G$ and $g \in G$. Let

$$N := \bigoplus_{|G_i| \leq m(\varepsilon), 1 \leq i \leq n} G_i,$$

Since the functions $G_i$ are pairwise non-isomorphic, $|N| < f(\varepsilon)$ for some function $f : \mathbb{R}^+ \to \mathbb{Z}^+$.

Let $\overline{S} := \pi_N(S)$, where

$$\pi_N : G \to \overline{G} := \bigoplus_{|G_i| > m(\varepsilon), 1 \leq i \leq n} G_i$$

is the natural projection. For any subgroup $\overline{H}$ of $\overline{G}$ and $\overline{g} \in \overline{G}$, by (42) we have

$$P_{\overline{S}}(\overline{g}H) < [\overline{G} : H]^{-\varepsilon}|\overline{G}|^{\delta(\varepsilon)/2};$$

and so

$$\frac{1}{|N|} P_{\overline{S}}(\overline{gH}) \leq \frac{|\overline{S}|}{|S|} P_S(gH) < [\overline{G} : H]^{-\varepsilon}|\overline{G}|^{\delta(\varepsilon)/2}|N|^{\delta(\varepsilon)/2}. $$

This implies that

$$P_{\overline{S}}(\overline{gH}) \leq [\overline{G} : H]^{-\varepsilon}|\overline{G}|^{\delta(\varepsilon)/2} f(\varepsilon)^{1+\delta(\varepsilon)/2}.$$ 

If $|\overline{G}| > f(\varepsilon)^{1+\delta(\varepsilon)/2}$, then we get $P_{\overline{S}}(\overline{gH}) \leq [\overline{G} : H]^{-\varepsilon}|\overline{G}|^{\delta(\varepsilon)}$. Therefore, by our assumption

$$|\overline{S}|^{1+\delta(\varepsilon)} \leq C(\varepsilon) |\overline{S} \cdot \overline{S} \cdot \overline{S}|.$$ 

Hence,

$$|S|^{1+\delta(\varepsilon)} \leq f(\varepsilon)^{1+\delta(\varepsilon)} C(\varepsilon) |S \cdot S \cdot S|. $$
If $|G| < f(\varepsilon)^{1 + \frac{\delta(\varepsilon)}{2}}$, then $|S| \leq |G| < f(\varepsilon)^{1 + \frac{\delta(\varepsilon)}{2}}$. Overall, we get

$$|S|^{1 + \delta(\varepsilon)} \leq C'(\varepsilon)|S \cdot S \cdot S|,$$

where $C'(\varepsilon) := \max\{f(\varepsilon)^{2+\frac{\delta(\varepsilon)}{2}}, f(\varepsilon)^{1+\delta(\varepsilon)}C(\varepsilon)\}$; and claim follows.

We show that for small enough $\varepsilon$ we can take

$$\delta(\varepsilon) := \min\{\varepsilon^5, 1\}/8L. \quad (43)$$

For the given $\delta(\varepsilon)$ and a positive valued function $C''(\varepsilon)$, we let

$$m(\varepsilon) := \sup\{x \in \mathbb{R}^+ | C''(\varepsilon) \log x \geq x^{\delta(\varepsilon)^2}\}.$$

By Lemma 43, we can and will assume that

$$C''(\varepsilon) \log |G_i| < |G_i|^{\delta(\varepsilon)^2} \quad (44)$$

for any $i$. Throughout the proof of Proposition 33, we will be assuming inequalities of the type given in (44).

As it is discussed in the beginning of [48, Section 3.2], passing to the groups $G_i/Z(G_i)$, using an argument similar to Lemma 43 and based on an inequality of type (44), we can and will assume that the functions $G_i$ are simple groups.

For any non-empty subset $I$ of $[1..n]$, we let $G_I := \bigoplus_{i \in I} G_i$; sometimes we view $G_I$ as a subgroup of $G_J$ when $I \subseteq J$. We let $G_\emptyset = \{1\}$. For any $I \subseteq J \subseteq [1..n]$, we let $\text{pr}_J : G_J \to G_I$ be the natural projection map.

**Definition 44.** A subset $A$ of $\bigoplus_{i=1}^n G_i$ is called $(m_0, \ldots, m_{n-1})$-regular if for any $0 \leq k < n$ and $\bar{x} \in \text{pr}_{[1..k]}(A)$ we have

$$|\{x \in \text{pr}_{[1..k+1]}(A) | \text{pr}_{[1..k]}(x) = \bar{x}\}| = m_k.$$

For a random variable $X$ with values in $\bigoplus_{i=1}^n G_i$, we write $X = (X_1, \ldots, X_n)$ and get random variables $X_i$ with values in $G_i$.

**Lemma 45.** Suppose $A \subseteq \bigoplus_{i=1}^n G_i$ is an $(m_1, \ldots, m_n)$-regular subset. Let $X$ be a random variable with respect to the probability counting measure on $A$. Then,

(1) $\text{pr}_{[1..k]}(X)$ is a random variable with respect to the probability counting measure on $\text{pr}_{[1..k]}(A)$;

(2) for any $(a_1, \ldots, a_n) \in A$, the conditional probability measure

$$\mathbb{P}(X_k | X_1 = a_1, \ldots, X_{k-1} = a_{k-1})$$

is a probability counting measure on a set of size $m_k$.

**Proof.** Both of the above claims are easy consequences of the fact that $A$ is a regular set (see [40, Lemma 22]).
The filtration \( \{1\} = G_\emptyset \subseteq G_{[1]} \subseteq \cdots \subseteq G_{[1..i]} \subseteq \cdots \subseteq G_{[1..n]} \) gives us a rooted tree structure, where the vertices at the level \( i \) are the elements of \( G_{[1..i]} \); and the children of \((a_1, \ldots, a_i) \) are elements of \( (a_1, \ldots, a_i) \oplus G_{[i+1]} \). To a non-empty subset \( A \) of \( G_{[1..n]} \), we associate the rooted subtree consisting of paths from the root to the elements of \( A \). So a subset \( A \) is \((m_0, \ldots, m_{n-1})\)-regular precisely when the vertices at the level \( i \) of the associated rooted tree of \( A \) has exactly \( m_i \) children.

As it has been discussed in [48, Section 3.2] by [5, Lemma 5.2] and inequality (44) (see also [4, A.3] and [38, Section 2.2]), we get that there is a \((D_0, \ldots, D_{n-1})\)-regular subset \( A \) of \( S \) such that the following holds.

1. For any \( i \), either \( D_i > |G_i|^\delta \) or \( D_i = 1 \).
2. \(|A| > (\prod_{i=1}^n |G_i|)^{-2\delta}|S|\).

### 4.4 Scales with no room for improvement

This section is identical to [48, Section 3.4]. The change in the assumptions has no effect in this part of the proof. We have decided to include the proofs for the convenience of the reader.

Let \( I_l := \{i \in [0..n-1] \mid D_i \geq |G_i|^{1-1/(3L)}\} \), and \( I_s := [0..n-1] \setminus I_l \). Suppose \( X = (X_1, \ldots, X_n) \) is the random variable with respect to the probability counting measure on \( A \).

**Lemma 46.** In the above setting, \( \text{pr}_{I_l}(A \cdot A \cdot A) = G_{I_l} \).

**Proof.** (See the beginning of [48, Section 3.4]) Let us recall that \( A \) is a \((D_0, \ldots, D_{n-1})\)-regular set. Suppose \( I \) is a subset \([0..n-1]\) such that for any \( i \in I \), \( D_i > |G_i|^{1-1/(3L)} \). By induction on \(|I|\), we prove that \( \text{pr}_{I}(A \cdot A \cdot A) = G_{I} \). The base of induction follows from Theorem 40. Suppose \( I = \{i_1, \ldots, i_{m+1}\} \) and \( i_1 < \cdots < i_{m+1} \). By the induction hypothesis,

\[
\text{pr}_{\{i_1, \ldots, i_m\}}(A \cdot A \cdot A) = G_{I \setminus \{i_{m+1}\}}.
\]

So for any \((g_{i_1}, \ldots, g_{i_m}) \in G_{I \setminus \{i_{m+1}\}}\), there are \( a_1, a_2, a_3 \in A \) such that

\[
\text{pr}_{\{i_1, \ldots, i_m\}}(a_1 a_2 a_3) = (g_{i_1}, \ldots, g_{i_m}). \tag{45}
\]

Let

\[
A(a_j) := \{a \in A \mid \text{pr}_{[1..i_{m+1}-1]}(a) = \text{pr}_{[1..i_{m+1}-1]}(a_j)\}.
\]

Then \(|\text{pr}_{i_{m+1}}(A(a_j))| = D_{i_{m+1}} > |G_{i}^{1-1/(3L)}|\); and so by Theorem 40, we have

\[
\text{pr}_{i_{m+1}}(A(a_1)a_2A(a_3)) = \text{pr}_{i_{m+1}}(A(a_1))pr_{i_{m+1}}(A(a_2))pr_{i_{m+1}}(A(a_3)) = G_{i_{m+1}}. \tag{46}
\]

By (45) and (46), we have

\[
\text{pr}_{I}(A \cdot A \cdot A) = G_{I};
\]

and claim follows.
Let $I_s := [0..n - 1] \setminus I_l$, and for $g, g' \in G_{I_s}$, let

$$d(g, g') := \sum_{i \in I_s, \text{pr}_i(g) \neq \text{pr}_i(g')} \log |G_i|.$$ 

It is easy to see that $d(., .)$ defines a metric on $G_{I_s}$. Let

$$T := \max \{d(g_s, 1) | g_s \in \bigcup_{i=1}^3 \text{pr}_i((\prod_{i=1}^3 S) \cap \{1\} \oplus G_{I_s})\};$$

here we rearranging components of $G_{[1..n]}$ and identifying it with $G_{I_l} \oplus G_{I_s}$. For any $g_l \in G_{I_l}$, let $\psi(g_l) \in G_{I_s}$ be such that

$$(g_l, \psi(g_l)) \in A \cdot A \cdot A;$$

note that by Lemma 46 there is such a $\psi(g_l)$.

**Lemma 47.** In the above setting $\psi : G_{I_l} \rightarrow G_{I_s}$ is a $T$-approximate homomorphism; that means for any $g, g' \in G_{I_l}$ we have

$$d(\psi(gg'), \psi(g)\psi(g')) \leq T \text{ and } d(\psi(g^{-1}), \psi(g)^{-1}) \leq T.$$ 

**Proof.** For $g, g' \in G_{I_l}$, we have $(g, \psi(g)), (g', \psi(g')), (gg', \psi(gg')) \in A \cdot A \cdot A$; and so

$$(1, \psi(gg')\psi(g)^{-1}\psi(g')^{-1}) \in \prod_{i=1}^n S \cap \{1\} \oplus G_{I_s} \text{ and } (1, \psi(g^{-1})\psi(g)) \in \prod_{i=1}^n S \cap \{1\} \oplus G_{I_s};$$

and claim follows as $d(g, g')$ is $G_{I_s}$-bi-invariant. \hfill \square

By [17, Theorem 2.1], there is a group homomorphism $\widetilde{\psi} : G_{I_l} \rightarrow G_{I_s}$ such that for $g \in G_{I_l}$

$$d(\psi(g), \widetilde{\psi}(g)) \leq 24T. \quad (47)$$

**Lemma 48.** In the above setting, let $H$ be the graph of $\widetilde{\psi}$; then for any $g \in S$, there is $I_s(g) \subseteq I_s$ such that the following holds.

1. $g \in HG_{I_s(g)}$ where $G_{I_s(g)}$ is viewed as a subgroup of $G_{[1..n]}$.
2. $|G_{I_s(g)}| \leq 2^{25T}.$

**Proof.** Suppose $g = (g_l, g_s)$ for some $g_l \in G_{I_l}$ and $g_s \in G_{I_s}$; then $d(\psi(g_l), g_s) \leq T$. By (47), we have $d(\widetilde{\psi}(g_l), \psi(g_l)) \leq 24T$; and so

$$d(g_s, \widetilde{\psi}(g_l)) \leq 25T. \quad (48)$$

Let $h := (g, \widetilde{\psi}(g_l)) \in H$; and consider $h^{-1} g = (1, \widetilde{\psi}(g_l)^{-1} g_s).$ Let

$$I_s(g) := \{ j \in I_s | \text{pr}_j(g_s) \neq \text{pr}_j(\widetilde{\psi}(g_l))\};$$
and so $h^{-1}g \in G_{I_s(g)}$. By (48), we have
\[
\sum_{j \in I_s(g)} \log |G_j| \leq 25T,
\]
which implies that $|G_{I_s(g)}| \leq 2^{25T}$; and the claim follows. \hfill \Box

**Lemma 49.** In the above setting, under the assumptions that $\delta \ll \varepsilon^2 \ll 1$ (as in (43)) and an inequality of type (44) hold, either $|\prod_3 S| > |G_{[1..n]}|^{1-\varepsilon+\delta}$ or $T \gg \varepsilon^2 \log |G_{[1..n]}|$; that means either $|\prod_3 S| > |G_{[1..n]}|^{1-\varepsilon+\delta}$ or there is
\[
(1, g_s) \in \bigcup_{i=1}^3 (\prod S) \cap \{(1) \oplus G_{I_s}\}
\]
such that $d(g_s, 1) \gg \varepsilon^2 \log |G_{[1..n]}|$.

This can be interpreted as the existence of an element with small height and large centralizer; it has some conceptual similarities with [38, Proposition 57].

**Proof of Lemma 49.** By Lemma 48, we have
\[
S \subseteq \bigcup_{I' \subseteq I_s, |G_{I'}| \leq 2^{25T}} HG_{I'}.
\]
Therefore, we have
\[
1 = P_S \left( \bigcup_{I' \subseteq I_s, |G_{I'}| \leq 2^{25T}} HG_{I'} \right) \leq \sum_{I' \subseteq I_s, |G_{I'}| \leq 2^{25T}} P_S(HG_{I'}) \leq 2^{25T} |G_{[1..n]} : H|^{-\varepsilon} |G_{[1..n]}|^\delta = 2^{25T} |G_{I_s}|^{1-\varepsilon} |G_{[1..n]}|^\delta \\
\leq 2^{25T} |G_{I_s}|^{1-\varepsilon/2} |G_{[1..n]}|^\delta. \quad (2^{25T} \leq |G_{I_s}|^{1/2} \text{ by inequality (44)}) (49)
\]
Let us assume that $|\prod_3 S| \leq |G_{[1..n]}|^{1-\varepsilon+\delta}$; then
\[
|G_{I_s}| \leq |\prod_3 S| \leq |G_{[1..n]}|^{1-\varepsilon+\delta},
\]
which implies
\[
|G_{[1..n]}|^{\varepsilon/2} \leq |G_{[1..n]}|^{\varepsilon-\delta} \leq |G_{I_s}|. \quad (50)
\]
By (49) and (50), we have
\[
2^{25T} \geq |G_{[1..n]}|^{(\varepsilon/2)^2-\delta} \geq |G_{[1..n]}|^{\varepsilon^2/8},
\]
and the claim follows. \hfill \Box
Lemma 50. In the above setting, for any \( g \in G_{[1..n]} \), we have
\[
|\{ s g s^{-1} \mid s \in S \}| \geq |Cl(g)|^2 |G_{[1..n]}|^{-\delta},
\]
where \( Cl(g) \) is the conjugacy class of \( g \) in \( G_{[1..n]} \).

Proof. Because of the bijection between conjugates of \( g \) and cosets of the centralizer \( C_{G_{[1..n]}}(g) \) of \( g \) in \( G_{[1..n]} \), we have
\[
|\{ s g s^{-1} \mid s \in S \}| = |\{ s C_{G_{[1..n]}}(g) \mid s \in S \}|.
\]
On the other hand,
\[
1 = P_S(\bigcup_{s \in S} s C_{G_{[1..n]}}(g)) = P_S(\bigcup_{\tilde{s} \in C(g;S)} \tilde{s}) \leq \sum_{\tilde{s} \in C(g;S)} P_S(\tilde{s});
\]
and by our assumption
\[
P_S(\tilde{s}) \leq [G_{[1..n]} : C_{G_{[1..n]}}(g)]^{-\varepsilon} |G_{[1..n]}|^{-\delta} = |Cl(g)|^{-\varepsilon} |G_{[1..n]}|^{-\delta},
\]
for any \( \tilde{s} \in C(g;S) \). Hence, we have
\[
|Cl(g)|^2 |G_{[1..n]}|^{-\delta} \leq |C(g;S)|;
\]
and the claim follows.

Proposition 51. In the above setting, either
\[
|\prod_{i=1}^{3} S| > |G_{[1..n]}|^{1-\varepsilon+\delta}
\]
or
\[
|\prod_{i=1}^{14} S| \geq |G_{[1..n]}|^{\Theta_L(\varepsilon^3)} |G_{I_s}|.
\]

Proof. If \( |\prod_{i=1}^{3} S| \leq |G_{[1..n]}|^{1-\varepsilon+\delta} \), then by Lemma 49 there is
\[
(1, g_k) \in \bigcup_{i=1}^{3} (\prod_{i=1}^{3} S) \cap (\{ 1 \} \Theta_G I_s)
\]
such that \( d(g_k, 1) \gg \varepsilon^2 \log |G_{[1..n]}| \). Note that
\[
|Cl(1, g_k)| = [G_{[1..n]} : C_{G_{[1..n]}}(1, g_k)] = \prod_{i \in I_s} [G_i : C_{G_i}(pr_i g_k)] \geq 2^{d(g_k, 1)/L} \geq |G_{[1..n]}|^{\Theta_L(\varepsilon^2)}. \tag{51}
\]
Let us recall that there is a function \( \psi : G_{I_s} \to G_{I_s} \) such that graph \( H_{\psi} \) of \( \psi \) is a subset of \( \prod_{i=1}^{3} S \). Since \( Cl(1, g_k) \subseteq \{ 1 \} \Theta_G I_s \), we have
\[
| Cl(1, g_k) H_{\psi} | = | Cl(1, g_k) | G_{I_s} |.
\]
Note that
\[
\prod_{i=1}^{11} S \supseteq \{ s(1, g_k)s^{-1} \mid s \in S \}. \tag{53}
\]
Hence by (51)–(53), and Lemma 50, we have
\[ |\prod_{14} S| \geq |G_{[1..n]}|^{\Theta_L(\varepsilon^3)}|G_{[1..n]}|^{-\delta}|G_{[1]}| \geq |G_{[1..n]}|^{\Theta_L(\varepsilon^3)}|G_{[1]}|;\]
and claim follows. □

4.5 Combining Diophantine property of a distribution with entropy of another one

The main goal of this section is to prove Proposition 41. So, this section is all about a single scale. Roughly speaking, we start with two distributions on a finite group that satisfies (V1)$_L$−(V3)$_L$; we assume one of them has a certain Diophantine property and the other one has an entropy proportional to the entropy of the uniform distribution. We will show lots of certain convolutional distributions have both of these properties at the same time.

In this section, $G$ is a finite group that satisfies (V1)$_L$−(V3)$_L$, and $m \leq L$ and $m' \leq L \log |G|$ are positive integers given in (V3)$_L$.

The next lemma says if we have a Diophantine type property for a distribution $\nu$ for subgroups of given complexity, then not many subgroups of the next level of complexity can fail a Diophantine type property of a similar order.

We note that because of (V3)$_L$−(v) the extra type $\{H'_i\}_{i=1}^{m'}$ of subgroups do not cause any problem and Varjú’s argument works in our setting as well.

**Lemma 52.** Suppose $G$ is a finite group that satisfies (V3)$_L$ and $m \leq L$ is a positive integer given in (V3)$_L$. Suppose $\nu$ is a probability measure on $G$, $1 \leq k \leq m$ is an integer, and $0 < p, p' < 1$ with the following properties.

1. For any $H \in \bigcup_{i=1}^k \mathcal{H}_i$ and for any $g \in G$, $\nu(gH) < p$.
2. $p' > \sqrt{2Lp}$.

If $k < m$, let
\[ E_{k+1}(\nu; p, p') := \{ H \in \mathcal{H}_{k+1} | \tilde{\nu} * \nu(H) > p' \}. \]
If $k = m$, for any $i \in [1..m']$, let
\[ E'_i(\nu; p, p') := \{ H \in \mathcal{H}_i' | \tilde{\nu} * \nu(H) > p' \}. \]

Then $|E_{k+1}(\nu; p, p')|$ and $|E'_i(\nu; p, p')|$ are less than $\sqrt{\frac{2}{Lpp'}}$.

**Proof** (See toward the end of proof of [48, Lemma 18]). First we consider the case $k < m$. For two distinct elements $H, H' \in E_{k+1}(\nu; p, p')$, there is $H^\sharp \in \mathcal{H}_j$ for some $j \leq k$ such that $[H \cap H' : H^\sharp \cap H \cap H'] \leq L$. Hence, $\nu(g(H \cap H')) \leq Lp$, which implies
\[ \tilde{\nu} * \nu(H \cap H') \leq Lp. \] (54)
For any $1 \leq l \leq |E_{k+1}(\nu; p, p')|$, suppose $H_1, \ldots, H_l$ are distinct elements of $E_{k+1}(\nu; p, p')$; then

$$1 \geq \bar{\nu} \ast \nu \left( \bigcup_{i=1}^{l} H_i \right) \geq \sum_{i=1}^{l} \bar{\nu} \ast \nu (H_i) - \sum_{1 \leq i < j \leq l} \bar{\nu} \ast \nu (H_i \cap H_j) \geq l p' - \left( \frac{l}{2} \right) L p. \quad (55)$$

Let $f(x) := -\frac{L p}{2} x^2 + (p' + \frac{L p}{2}) x - 1$; then by (55) for any $l \in [1..|E_{k+1}(\nu; p, p')|]$, $f(l) \leq 0$. We note that

$$f \left( \frac{2}{p' + L p/2} \right) = - \frac{L p}{2} \left( \frac{2}{p' + L p/2} \right)^2 + (p' + L p/2) \left( \frac{2}{p' + L p/2} \right) - 1$$

$$= - \frac{L p}{2} \left( \frac{2}{p' + L p/2} \right)^2 + 1.$$

Since $p' > \sqrt{2Lp}$, we have $p' + Lp/2 > \sqrt{2Lp}$, which implies $\frac{p' + Lp/2}{2} > \sqrt{\frac{Lp}{2}}$. Hence,

$$f \left( \frac{2}{p' + L p/2} \right) > 0.$$

By the concavity of $f$, $f(-\infty) = -\infty$, $1 \geq 2/(p' + Lp/2)$, and the above discussion we deduce

$$|E_{k+1}(\nu; p, p')| < \frac{2}{p' + Lp/2} \leq \sqrt{\frac{2}{Lp p'}};$$

and claim follows in this case.

For the case of $k = m$, we note that for any two distinct elements $H, H' \in H_j$, there is $H^j \in H_j$ for some $j \leq m$ such that $[H \cap H' : H^j \cap H \cap H'] \leq L$. So, an identical argument as in the previous case works here as well.

Let us first recall the setting of Proposition 41; we will be working in this setting for the rest of this section.

(1) $G$ is a finite group that satisfies $(V2)_L$, $(V3)_L$ and $|G| \gg \alpha', \beta, L$ (the implied constant will be specified later).

(2) $X_1, \ldots, X_{2m+1}$ are independent random variables such that $H_\infty(X_i) \geq \alpha' \log |G|$.

(3) For any $l$-tuple $\vec{y} := (y_1, \ldots, y_l), X_{\vec{y}} := X_1 y_1 X_2 \cdots y_l X_{l+1}$; in addition we let

$$X'_{\vec{y}} := X_{l+2} y_1 X_{l+3} \cdots y_l X_{2l+2}.$$

(4) $Y_1, \ldots, Y_{2m+1-1}$ are independent and identically distributed random variables with values in $G$ such that for any $H$ in $\bigcup_{i=1}^{m} H_i$ and $g \in G$, $\mathbb{P}(Y_1 \in gH) \leq [G : H]^{-\beta}$; and moreover for any subgroup $H$ with order at least $|G|^\alpha$ and any $g \in G$, we have the same inequality; that means $\mathbb{P}(Y_1 \in gH) \leq [G : H]^{-\beta}$.

(5) $\beta \geq 4\alpha$; in fact it is enough to assume $(1 - \frac{1}{L})\beta \geq \alpha$. 
Lemma 53. In the above setting, let $$\beta_0 := \min(\frac{\beta}{5L}, \frac{\alpha'}{2})$$, $$\beta_k := \frac{\beta_0}{8k}$$ and $$p_k := (2^k - 1)|G|^{-\beta/(2L)}$$; then for any $$1 \leq k \leq m$$

$$P((Y_1, ..., Y_{2^k-1}) = \bar{y} \text{ such that } \exists H \in \bigcup_{j=0}^{k} H_j, \exists g \in G, P(X_{\bar{y}} \in gH) \geq |G|^{-\beta_k}) \leq p_k.$$  

Proof (See proof of [48, Lemma 18].). We proceed by induction on $$k$$. To deal with the base of induction in the same venue as in the induction step, we consider the case of $$k = 0$$ as well; in the sense that we show why we have $$P(X_1 \in gZ(G)) < |G|^{-\beta_0}$$ for any $$g \in G$$.

Since $$H_\infty(X) \geq \alpha' \log |G|$$ and $$|Z(G)| \leq L$$, we have $$P(X_1 \in gZ(G)) < L|G|^{-\alpha'} \leq |G|^{-\alpha'/2}$$ (the second inequality holds as $$|G| \gg \alpha', L$$ 1); and this implies the case of $$k = 0$$.

Next we focus on the induction step; let

$$E_k := \{\bar{y} \in \bigoplus_{i=1}^{2^k-1} G | \exists H \in \bigcup_{i=0}^{k} H_i, \exists g \in G, P(X_{\bar{y}} \in gH) \geq |G|^{-\beta_k}\},$$

and

$$E'_k := \{\bar{y} \in \bigoplus_{i=1}^{2^k-1} G | \exists H \in \bigcup_{i=0}^{k} H_i, \exists g \in G, P(X'_{\bar{y}} \in gH) \geq |G|^{-\beta_k}\}.$$  

By the induction hypothesis, we have that these are exceptional sets:

$$P((Y_1, ..., Y_{2^k-1}) \in E_k) \leq p_k \text{ and } P((Y_{2^k+1}, ..., Y_{2^{k+1}-1}) \in E'_k) \leq p_k.$$  

Suppose $$\bar{y} := (\bar{y}_l, y, \bar{y}_r) \in E_{k+1}$$ where $$\bar{y}_l$$ and $$\bar{y}_r$$ are the left and the right $$2^k - 1$$ components of $$\bar{y}$$, respectively, and $$y \in G$$. Then $$X_{\bar{y}} = X_{\bar{y}_l} y X'_{\bar{y}_r}$$ and there are $$H \in \bigcup_{i=0}^{k+1} H_i$$ and $$g \in G$$ such that

$$|G|^{-\beta_{k+1}} \leq P(X_{\bar{y}_l} y X'_{\bar{y}_r} \in gH) = \sum_{j=1}^{[G:H]} P(X_{\bar{y}_l} \in gH g_j) P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H),$$

where $$\{g_j\}_{j=1}^{[G:H]}$$ is a set of right coset representatives of $$H$$. Let

$$I_l := \{j \in [1..[G : H]] | P(X_{\bar{y}_l} \in gH g_j) \leq P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H)\}$$

and

$$I_r := \{j \in [1..[G : H]] | P(X_{\bar{y}_l} \in gH g_j) > P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H)\}.$$  

Let $$q_l := \max_{j \in I_l} P(X_{\bar{y}_l} \in gH g_j)$$ and $$q_r := \max_{j \in I_r} P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H)$$; then

$$\sum_{j \in I_l} P(X_{\bar{y}_l} \in gH g_j) P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H) \leq q_l,$$

and

$$\sum_{j \in I_r} P(X_{\bar{y}_l} \in gH g_j) P(X'_{\bar{y}_r} \in y^{-1} g_j^{-1} H) \leq q_r.$$
Therefore by (59), we have
\[
\frac{1}{2} |G|^{-\beta_{k+1}} \leq \max(q_l, q_r),
\]
which implies that there is \( j_0 \) such that
\[
\frac{1}{2} |G|^{-\beta_{k+1}} \leq \mathbb{P}(X_{y_l} \in g H g_{j_0}) \quad \text{and} \quad \frac{1}{2} |G|^{-\beta_{k+1}} \leq \mathbb{P}(X_{y_r}' \in y^{-1} g_{j_0}^{-1} H).
\] (60)

For a random variable \( U \) with values in \( G \), let \( \tilde{U} \) be a random variable independent of \( U \) with a distribution similar to \( U^{-1} \). Then by (60), we have
\[
\mathbb{P}(\tilde{X}_{y_l} \in g H g_{j_0}) \geq \frac{1}{4} |G|^{-2\beta_k+1} \quad \text{and} \quad \mathbb{P}(X_{y_r}' \in y^{-1} g_{j_0}^{-1} H) \geq \frac{1}{4} |G|^{-2\beta_{k+1}}.
\] (61)

It \( y_l \not\in \mathcal{E}_k \), then \( \mathbb{P}(X_{y_l} \in g H) < |G|^{-\beta_k} \) for any \( H \in \bigcup_{i=0}^{k} \mathcal{H}_i \) and any \( g \in G \). This implies that
\[
g_{j_0}^{-1} H g_{j_0} \in E_{k+1}(\lambda_{y_l}; |G|^{-\beta_k}, \frac{1}{4} |G|^{-2\beta_{k+1}}),
\] (62)
where \( \lambda_{y_l} \) is the distribution of the random variable \( X_{y_l} \) and \( E_{k+1} \) is the set defined in Lemma 52.

By a similar argument, if \( y_r \not\in \mathcal{E}_k' \), then
\[
y^{-1} g_{j_0}^{-1} H g_{j_0} y \in E_{k+1}(\lambda_{y_r}'; |G|^{-\beta_k}, \frac{1}{4} |G|^{-2\beta_{k+1}}),
\] (63)
where \( \lambda_{y_r}' \) is the distribution of the random variable \( X_{y_r}' \). So far by (62), (63), and we have
\[
\mathbb{P}((\tilde{y}_l, y, \tilde{y}_r) \in \mathcal{E}_{k+1}) \leq \mathbb{P}(\tilde{y}_l \in \mathcal{E}_k) + \mathbb{P}(\tilde{y}_r \in \mathcal{E}_k') + \mathbb{P}((\tilde{y}_l, y, \tilde{y}_r) \in \mathcal{E}_{k+1}, y_l \not\in \mathcal{E}_k, y_r \not\in \mathcal{E}_k')
\leq 2p_k + \sum_{\tilde{y}_l \not\in \mathcal{E}_k, \tilde{y}_r \not\in \mathcal{E}_k'} \mathbb{P}((Y_{1, \ldots, Y_{2k-1}} = \tilde{y}_l) \mathbb{P}((Y_{2k+1, \ldots, Y_{2k+1-k}} = \tilde{y}_r) \mathbb{P}(Y_{2k}^{-1} H_1 Y_{2k} = H_2, H_1, H_2)
\) (64)

where \( H_1 \) ranges in \( E_{k+1}(\lambda_{y_l}; |G|^{-\beta_k}, \frac{1}{4} |G|^{-2\beta_{k+1}}) \) and \( H_2 \) ranges in \( E_{k+1}(\lambda_{y_r}'; |G|^{-\beta_k}, \frac{1}{4} |G|^{-2\beta_{k+1}}) \). For a given \( H_1 \) and \( H_2 \) that are conjugate of each other and are in \( \mathcal{H}_i \) for some \( i \) there is \( g' \in G \) such that
\[
\mathbb{P}(Y_{2k}^{-1} H_1 Y_{2k} = H_2) = \mathbb{P}(Y_{2k} \in g' N_G(H_1));
\]
and by our assumption there is \( H^j \in \mathcal{H}_j \) for some \( j \) such that \( N_G(H_1) \leq_L H^j \). Hence,
\[
\mathbb{P}(Y_{2k}^{-1} H_1 Y_{2k} = H_2) \leq L[|G : H^j|]^{-\beta} \leq L|G|^{-\beta/L}.
\] (65)
By (64), (65), and Lemma 52, we have
\[
\mathbb{P}(\vec{y}_l, y, \vec{y}_r) \in \mathcal{E}_{k+1}) \leq 2p_k + \sum_{\vec{y}_l \not\in \mathcal{E}_k, \vec{y}_r \not\in \mathcal{E}_k'} \mathbb{P}(Y_1, \ldots, Y_{2^k-1} = \vec{y}_l)\mathbb{P}(Y_{2^k+1}, \ldots, Y_{2^k+1-1} = \vec{y}_r)
\]
\[
\left(\frac{L|G|^{-\beta/L}}{L|G|^{-\beta_k}|G|^{-2\beta_{k+1}/4}}\right)
\]
\[
\leq 2p_k + 8|G|^{-\frac{\beta}{L} + \beta_k + 2\beta_{k+1}}.
\]
(66)

By (66), to prove the claim it is enough to show that \(2p_k + 8|G|^{-\frac{\beta}{L} + \beta_k + 2\beta_{k+1}} \leq p_{k+1}\). We note that
\[
p_{k+1} - 2p_k = |G|^{-\frac{\beta}{2L}} - \frac{\beta_k + 2\beta_{k+1}}{4} \leq -\frac{3\beta}{4L}.
\]

Hence, it is enough to show \(8|G|^{-\frac{3\beta}{4L}} \leq |G|^{-\frac{\beta}{2L}}\), which clearly holds for \(|G| \gg \beta, L\).

\[\square\]

**Lemma 54.** In the above setting, let \(p := (2m+1-1)|G|^{-\beta/(2L)}\), \(\beta_0 := \min(\frac{\beta}{5L}, \frac{\alpha'}{2})\), and \(\beta' := \frac{\beta_0}{8m+1}\); then
\[
\mathbb{P}(Y_1, \ldots, Y_{2m+1-1}) = \vec{y} \text{ s.t. } \exists H \in \bigcup_{i=0}^{m'} H'_i, \exists g \in G, \mathbb{P}(X_{\vec{y}} \in gH) \geq |G|^{-\beta'} \leq p.
\]

**Proof.** We follow an identical argument as in the proof of Lemma 53. Let
\[
\mathcal{E}' := \{\vec{y} \in \bigoplus_{i=1}^{2^m-1} G | \exists H \in \bigcup_{i=1}^{m'} H'_i, \exists g \in G, \mathbb{P}(X_{\vec{y}} \in gH) \geq |G|^{-\beta'}\}.
\]
(67)

Suppose \(\vec{y} := (\vec{y}_l, y, \vec{y}_r) \in \mathcal{E}'\) where \(\vec{y}_l\) and \(\vec{y}_r\) are the left and the right \(2^m - 1\) components of \(\vec{y}\), respectively, and \(y \in G\). Then \(X_{\vec{y}} = X_{\vec{y}_l}yX_{\vec{y}_r}'\), and there are \(1 \leq i \leq m'\), \(H \in H'_i\), and \(g \in G\) such that \(|G|^{-\beta'} \leq \mathbb{P}(X_{\vec{y}_l}yX_{\vec{y}_r}' \in gH)\). As in the proof of Lemma 53, there is \(g' \in G\) such that
\[
\mathbb{P}(X_{\vec{y}_l}yX_{\vec{y}_r}' \in g^{-1}Hg') \geq \frac{1}{4}|G|^{-2\beta'}\text{ and } \mathbb{P}(X_{\vec{y}_l}yX_{\vec{y}_r}' \in y^{-1}g'^{-1}Hg' y) \geq \frac{1}{4}|G|^{-2\beta'}.\]
(68)

If \(\vec{y}_l \not\in \mathcal{E}_m\) where \(\mathcal{E}_m\) is defined in (56), then by Lemma 53 for any \(H \in \bigcup_{i=0}^{m} H_i\) and any \(g \in G\) we have \(\mathbb{P}(X_{\vec{y}} \in gH) < |G|^{-\beta_m}\) where \(\beta_m = \frac{\beta_0}{8m}\). This implies that
\[
g'^{-1}Hg' \in E'_i(\lambda_{\vec{y}_l}, |G|^{-\beta_m}, \frac{1}{4}|G|^{-2\beta'}),
\]
(69)

where \(E'_i\) is the set defined in Lemma 52. Similarly, if \(\vec{y}_r \not\in \mathcal{E}'_m\) where \(\mathcal{E}'_m\) is defined in (57), then
\[
y^{-1}g'^{-1}Hg'y \in E'_i(\lambda_{\vec{y}_r}, |G|^{-\beta_m}, \frac{1}{4}|G|^{-2\beta'}).
\]
(70)
Following an identical argument as in the proof of Lemma 53, we get

\[
\mathbb{P}((\vec{y}_l, y, \vec{y}_r) \in \mathcal{E}') \leq \mathbb{P}(\vec{y}_l \in \mathcal{E}_m) + \mathbb{P}(\vec{y}_r \in \mathcal{E}_m') + \mathbb{P}((\vec{y}_l, y, \vec{y}_r) \in \mathcal{E}', \vec{y}_l \notin \mathcal{E}_m, \vec{y}_r \notin \mathcal{E}_m')
\]

\[
\leq 2p_m + \sum_{\vec{y}_l \notin \mathcal{E}_m, \vec{y}_r \notin \mathcal{E}_m'} \mathbb{P}(Y_1, \ldots, Y_{2m-1} = \vec{y}_l)\mathbb{P}(Y_{2m+1}, \ldots, Y_{2m+1-1} = \vec{y}_r)
\]

\[
\left( \sum_{i=1}^{m'} \sum_{H_1, H_2} \mathbb{P}(Y_{2m}^{-1}H_1Y_{2m} = H_2) \right),
\]

where \(p_m\) is given in Lemma 53, \(H_1\) ranges in \(E'(\lambda^-; |G|^{-\beta_m}, \frac{1}{4}|G|^{-2\beta'})\), and \(H_2\) ranges in \(E'(\lambda^-; |G|^{-\beta_m}, \frac{1}{4}|G|^{-2\beta'})\) for the given \(i\). We note that for a given \(H_1\) and \(H_2\) that are conjugate of each other and are in \(H'_i\), there is \(g'' \in G\) such that

\[
\mathbb{P}(Y_{2m}^{-1}H_1Y_{2m} = H_2) = \mathbb{P}(Y_{2m} \in g''N_G(H_1));
\]

and by our assumption \([N_G(H_1) : H_1] \leq L\). Hence,

\[
\mathbb{P}(Y_{2m}^{-1}H_1Y_{2m} = H_2) \leq L \max_{g \in G} \mathbb{P}(Y_{2m} \in gH_1).
\]

Now we consider two cases based on whether \(|H_1| \geq |G|^\alpha\) or not.

**Case 1.** \(|H_1| \geq |G|^\alpha\).

In this case, by our assumption,

\[
\max_{g \in G} \mathbb{P}(Y_{2m} \in gH_1) \leq [G : H_1]^{-\beta} \leq |G|^{-\frac{\beta}{L}};
\]

and so by an identical analysis as in the proof of Lemma 53 and our assumption that \(m' \leq \log |G|\), we deduce

\[
\mathbb{P}((\vec{y}_l, y, \vec{y}_r) \in \mathcal{E}') \leq 2p_m + 8L(\log |G|)|G|^{-\frac{\beta}{L} + \frac{\beta}{L} + \frac{2\beta'}{L}}.
\]

By (71) to prove the claim in this case, it is enough to show \(2p_m + 8L(\log |G|)|G|^{-\frac{\beta}{L} + \frac{\beta}{L} + \frac{2\beta'}{L}} \leq p\). We note that \(p - 2p_m = |G|^{-\beta/(2L)}\), and \(-\frac{\beta}{L} + \frac{\beta}{L} + 2\beta' \leq \frac{3\beta}{4L}\). Hence, it is enough to show

\[
8L(\log |G|)|G|^{-\frac{3\beta}{4L}} \leq |G|^{-\frac{\beta}{L}},
\]

which clearly holds for \(|G| \gg \beta, L\).

**Case 2.** \(|H_1| < |G|^\alpha\).

In this case, we have

\[
\max_{g \in G} \mathbb{P}(Y_{2m} \in gH_1) \leq |G|^{-\beta}|H_1| \leq |G|^{-\beta}|G|^\alpha \leq |G|^{-\frac{\beta}{L}},
\]

where the last inequality holds as \((1 - \frac{1}{L})\beta \geq \alpha\). Now we can follow the same analysis as in the first case; and the claim follows. \(\square\)
Proof of Proposition 41. First we note that we can and will let \( H_{m+1} := H_m \) and get the claim of Lemma 53 for \( k = m + 1 \) as well. Hence by Lemmas 53 and 54, we get
\[
P(\vec{y} \in E_{m+1} \cup E') \leq p_{m+1} + p' = 2(2^{m+1} - 1)|G|^\frac{\beta}{4 n} \leq |G|^\frac{\beta}{4 n},
\]
where \( E_{m+1} \) and \( E' \) are defined in (56) and (67), respectively, and the last inequality holds for \( |G| \gg L, \beta \).

Suppose \( \vec{y} \notin E_{m+1} \cup E' \). For any proper subgroup \( H \) of \( G \) proper, there is \( H^\sharp \in \bigcup_{i=0}^m H_i \cup \bigcup_{j=1}^{m'} H'_j \) such that \([H : H \cap H^\sharp] \leq L\). Then for any \( g \in G \)
\[
P(\vec{x}_y \in gH) \leq L \max_{g' \in G} P(\vec{x}_y \in g'\hat{H}) \leq L|G|^{-\beta'} \leq |G|^{-\beta'/2},
\]
where the last inequality holds for \( |G| \gg \beta, L \).

\[\square\]

4.6 | Gaining conditional entropy: Proof of Proposition 42

By the definition of the conditional Rényi entropy, we have
\[
H_2(X_1 Y_1 \cdots Y_{2^{m+1}-1} X_{2^m+1} X_{2^m+1+1} | Y_1, \ldots, Y_{2^m+1-1}) = 
\sum_{\vec{y} \in \Theta_{2^{m+1}-1} G} P((Y_1, \ldots, Y_{2^{m+1}-1}) = \vec{y}) H_2(X_\vec{y} X_{2^m+1+1}).
\] (72)

Let
\[
E'' := \{\vec{y} \text{ such that } X_\vec{y} \text{ is not of } (0, \beta'/2)-Diophantine \text{ type}\},
\]
where \( \beta' := \frac{1}{8^{m+1}} \min\left(\frac{\beta}{5 L}, \frac{\sigma'}{2}\right) \); and so by Proposition 41 we have
\[
P((Y_1, \ldots, Y_{2^{m+1}-1}) \in E'') \leq |G|^{-\frac{\beta}{4 n}}.
\] (73)

For \( \vec{y} \in E'' \), we use the trivial bound given in Lemma 37
\[
H_2(X_\vec{y} X_{2^m+1+1}) \geq 2^{m+1+1} \max_{i=1}^m H_2(X_i) \geq \min_{i=1}^{2^{m+1}+1} H_2(X_i) := h_{\min};
\] (74)
we note that \( H_2(X g) = H_2(X) \) for any random variable \( X \) with values in \( G \) and \( g \in G \). For \( \vec{y} \notin E'' \), we have

1. \( X_\vec{y} \) is of \((0, \beta'/2)-Diophantine \) type;
2. \( H_2(X_\vec{y}) \geq \max_{i=1}^{2^{m+1}} H_2(X_i) \geq \max_{i=1}^{2^{m+1}+1} H_\infty(X_i) \geq \alpha' \log |G| \) by Lemma 36, Lemma 37, and the fact that \( H_2(X_i | y_i) = H_2(X_i) \) for any \( i \).

Then either \( H_2(X_\vec{y}) > (1 - \frac{\alpha''}{2}) \log |G| \) or by Lemma 39
\[
H_2(X_\vec{y} X_{2^{m+1}+1}) \geq \frac{H_2(X_\vec{y}) + H_2(X_{2^{m+1}+1})}{2} + \gamma_0 \log |G|
\]
for some positive $\gamma_0$ which depends only on $\alpha', \alpha'', \beta$, and the function $\delta_0$. Since

$$\max_{i=1}^{2m+1+1} H_2(X_i) \leq (1 - \alpha'') \log |G|,$$

in either case we get

$$H_2(X_{\vec{y}}X_{2m+1+1}) \geq h_{\min} + \gamma_0 \log |G|. \quad (75)$$

In what follows, let $p_{\vec{y}} := \mathbb{P}((Y_1, \ldots, Y_{2m+1-1}) = \vec{y})$ for simplicity. By (72), (74), and (75), we have

$$H_2(X_1 Y_1 \cdots Y_{2m+1-1} X_{2m+1} X_{2m+1+1} | Y_1, \ldots, Y_{2m+1-1})$$

$$= \sum_{\vec{y} \in \mathcal{E}''} p_{\vec{y}} h_{\min} + \sum_{\vec{y} \notin \mathcal{E}''} p_{\vec{y}} (h_{\min} + \gamma_0 \log |G|)$$

$$= h_{\min} + \gamma_0 \mathbb{P}((Y_1, \ldots, Y_{2m+1-1}) \notin \mathcal{E}'') \log |G|$$

$$\geq h_{\min} + \gamma_0 (1 - |G|^{-\frac{\delta}{4\beta}}) \log |G|$$

$$\geq h_{\min} + \frac{\gamma_0}{2} \log |G|,$$

for $|G| \gg_1 \beta, \alpha', \alpha'', \delta_0$; and the claim follows.

4.7 Scales with room for improvement

In this section, we use the gain of conditional entropy (given in Proposition 42) at levels where we have room for improvement to prove a growth statement in the multi-scaled setting of Proposition 33. To use Proposition 42, we need to have an auxiliary random variable with some Diophantine property. We recall a result of Varjú that provides us with such a random variable.

Lemma 55. [48, Lemma 17] Suppose $\{G_i\}$ is a sequence of finite groups that are $L^{-1}$-quasi-random. Suppose $0 < \varepsilon < 1$, $0 < \delta < \varepsilon/(8L)$, and $S \subseteq G := \bigoplus_{i=1}^n G_i$ is such that for any proper subgroup $H$ of $G$ and $g \in G$ we have

$$P_S(gH) \leq |G : H|^{-\varepsilon}|G|^{\delta}.$$

Then there are $B \subseteq S$ and $J_g \subseteq [1..n]$ (think about it as the set of good indices) with the following properties. Let $Y := (Y^{(1)}, \ldots, Y^{(n)})$ be the random variable with the uniform distribution on $B$, and $Y^{(i)}$ be the induced random variable with values in $G_i$.

1. For $i \in J_g$, $Y^{(i)}$ is of $(0, \frac{\delta}{2L})$-Diophantine type.
2. Let $J_b := [1..n] \setminus J_g$ (think about it as the set of bad indices); then $|G_{J_b}| \leq |G|^{\frac{\delta}{2(2L)}}$, where $G_{J_b} := \bigoplus_{i \in J_b} G_i$.

Proof. See proof of [48, Lemma 17].
Let us recall some of our assumptions and earlier results that will be used in the remainder of this section.

1. \( \{G_i\}_{i=1}^{\infty} \) is a family of pairwise non-isomorphic finite groups that satisfy assumptions (V1), (V3), and (V4).
2. \( 0 < \varepsilon < 1 \) and \( \delta := \varepsilon^5/(8L) \).
3. Suppose \( |G_i| \gg \varepsilon L \) such that Proposition 42 holds for the variables \( \alpha' := \delta, \alpha'' := 1/(3L), \beta := \varepsilon/(2L), L, \) and \( \delta_0 \); we are allowed to make this assumption thanks to Lemma 43. Let \( \gamma \) be the constant given by Proposition 42 for the same set of variables.
4. \( S \subseteq G := \bigoplus_{i=1}^{n} G_i \) such that for any proper subgroup \( H \) of \( G \) and \( g \in G \)

\[
P_S(gH) \leq |G : H|^{-\varepsilon}|G|^\delta.
\]
5. Let \( A \subseteq S \) be the \( (D_0, \ldots, D_{n-1}) \)-regular subset that is given at the end of Subsection 4.3; that means \( D_i \) is either 1 or at least \( |G_i|^\delta \) and \( |A| > |G|^{-2\delta}|S| \).
6. Let \( I_1 := \{i \in [0..n-1] | D_i > |G_i|^{-1/(3L)} \} \) and \( I_0 := [0..n-1] \setminus I_1 \).
7. Let \( B \subseteq S \) be given by Lemma 55; and let \( J_g \) and \( J_b \) be given the sets given in same lemma.

In the above setting, we let \( X_i := (X^{(1)}_i, \ldots, X^{(n)}_i) \) be independent and identically distributed random variables with distribution \( P_A \) for \( 1 \leq i \leq 2m+1+1 \), and \( Y_i := (Y^{(1)}_i, \ldots, Y^{(n)}_i) \) be independent and identically distributed random variables with distribution \( P_B \) for \( 1 \leq i \leq 2m+1-1 \). For \( \vec{y} = (\vec{y}^{(1)}, \ldots, \vec{y}^{(n)}) \in \bigoplus_{i=1}^{2m+1-1} G_i \), we let

\[
p_{\vec{y}} := \mathbb{P}((Y_1, \ldots, Y_{2m+1-1}) = \vec{y}), \quad \text{and} \quad p_{\vec{y}^{(i)}} := \mathbb{P}((Y^{(i)}_1, \ldots, Y^{(i)}_{2m+1-1}) = \vec{y}^{(i)})
\]

and

\[
X_{\vec{y}} := X_1y_1X_2 \cdots y_{2m+1-1}X_{2m+1} = (X^{(1)}_1 y^{(1)}_1 X^{(1)}_2 \cdots y^{(1)}_{2m+1-1} X^{(1)}_{2m+1}, \ldots, X^{(n)}_1 y^{(n)}_1 X^{(n)}_2 \cdots y^{(n)}_{2m+1-1} X^{(n)}_{2m+1}).
\]

**Lemma 56.** In the above setting, we have

\[
\sum_{\vec{y} \in \bigoplus_{i=1}^{2m+1-1} G_i} p_{\vec{y}} H(X_{\vec{y}}X_{2m+1+1}) \geq \log |S| + \gamma \log |G_{I_0}| - \gamma \delta \frac{\log |G|}{\varepsilon/(3L)}.
\]

**Proof.** By Lemma 36, we have

\[
H(X_{\vec{y}}X_{2m+1+1}) = \sum_{i=1}^{n} H(X^{(i)}_{\vec{y}^{(i)}} X^{(i)}_{2m+1+1} | \mathbb{P}_{[1..i-1]}(X^{(i)}_{2m+1+1})) \geq \sum_{i=1}^{n} H(X^{(i)}_{\vec{y}^{(i)}} X^{(i)}_{2m+1+1} | \{\mathbb{P}_{[1..j-1]}(X^{(i)}_j)\}_{j=1}^{2m+1+1}).
\]
By (76), we get
\[
\sum_{\tilde{y} \in \bigoplus_{j=1}^{2m+1-1} G} p_H(X_{\tilde{y}}X_{2^{m+1}+1}) \geq \sum_{i=1}^{n} \sum_{\tilde{y} \in \bigoplus_{j=1}^{2m+1-1} G} p_H(X_{\tilde{y}(i)}X_{2^{m+1}+1} | \{\text{pr}_{[1..i-1]}(X_j)\}_{j=1}^{2^{m+1}+1})
\]
\[
= \sum_{i=1}^{n} \sum_{\tilde{y}(i) \in \bigoplus_{j=1}^{2m+1-1} G_i} p_H(X_{\tilde{y}(i)}X_{2^{m+1}+1} | \{\text{pr}_{[1..i-1]}(X_j)\}_{j=1}^{2^{m+1}+1}). \quad (77)
\]

We note that for a given \(1 \leq i \leq n\), we have
\[
h_i := \sum_{\tilde{y}(i) \in \bigoplus_{j=1}^{2m+1-1} G_i} p_H(X_{\tilde{y}(i)}X_{2^{m+1}+1} | \{\text{pr}_{[1..i-1]}(X_j)\}_{j=1}^{2^{m+1}+1}) = H(X_1Y_1X_2 \ldots Y_{i-1}X_{2^{m+1}+1} | \{\text{pr}_{[1..i-1]}(X_j)\}_{j=1}^{2^{m+1}+1}, \{Y_j\}_{j=1}^{2^{m+1}+1}). \quad (78)
\]

Note that if \(i \in I_g\) and \(D_i \neq 1\), then the conditional random variables \(X_{\tilde{y}(i)} | \text{pr}_{[1..i-1]}(X_j)\) satisfy the initial entropy and room for improvement conditions mentioned in Proposition 42. The initial entropy condition holds because \(D_i \geq |G_i|^5\), and the room for improvement condition holds because \(D_i \leq |G_i|^{1-1/(3L)}\). We also note that if \(i \in J_g\), then the random variables \(Y_{\tilde{y}(i)}\) satisfy the Diophantine condition mentioned in Proposition 42. Hence, for \(i \in J_g \cap I_g\) and \(D_i \neq 1\), by Proposition 42, we have
\[
h_i \geq \log D_i + \gamma \log |G_i|.
\]

By Lemma 37, we have the trivial bound
\[
h_i \geq \log D_i, \quad (80)
\]
for any \(i\). By (77)–(80), we get
\[
\sum_{\tilde{y} \in \bigoplus_{j=1}^{2m+1-1} G} p_H(X_{\tilde{y}}X_{2^{m+1}+1}) \geq \log |A| + \gamma \log |G_{J_g \cap I_g}|. \quad (81)
\]

We note that
\[
\log |G_{I_g}| = \log |G_{J_g \cap I_g}| + \log |G_{J_b \cap I_g}| \leq \log |G_{J_g \cap I_g}| + \log |G_{J_b}| \leq \log |G_{J_g \cap I_g}| + \frac{\delta}{\varepsilon/(2L)} \log |G|,
\]
and \(\log |A| \geq \log |S| - 2\delta \log |G|\). Hence by (81) and (82), we have
\[
\sum_{\tilde{y} \in \bigoplus_{j=1}^{2m+1-1} G} p_H(X_{\tilde{y}}X_{2^{m+1}+1}) \geq \log |S| + \gamma \log |G_{I_g}| - \gamma \delta(2 + \frac{2L}{\varepsilon}) \log |G|;
\]
and the claim follows.
Corollary 57. In the above setting, we have

$$\log |\prod_{2m+2} S| \geq \log |S| + \gamma \log |G_{t_2}| - \frac{\gamma \delta}{\varepsilon/(3L)} \log |G|.$$  

Proof. By Lemma 56, there is $\vec{y} \in B \times \cdots \times B$ such that

$$H(X_{\vec{y}}X_{2^m+1}) \geq \log |S| + \gamma \log |G_{t_2}| - \frac{\gamma \delta}{\varepsilon/(3L)} \log |G|.$$  

On the other hand, $H(X_{\vec{y}}X_{2^m+1}) \leq H_0(X_{\vec{y}}X_{2^m+1}) \leq \log |\prod_{2m+2} S|$; and the claim follows. □

4.8 Multi-scale product result: Proof of Proposition 33

In this section, we still work in the setting listed in the previous section, and finish the proof of Proposition 33.

By Proposition 51, we either have $|\prod_{3} S| \geq |G|^{1-\varepsilon+\delta}$ in which case the claim follows or

$$\log |\prod_{14} S| \geq \log |G_{t_4}| + \Theta_L(\varepsilon^3) \log |G|.$$  (83)

By Corollary 57, we have

$$\log |\prod_{2m+2} S| \geq \log |S| + \gamma \log |G_{t_2}| - \Theta_L(\gamma \varepsilon^4) \log |G|.$$  (84)

By (83) and (84), we get

$$(1 + \gamma) \log |\prod_{2m+2} S| \geq \log |S| + \gamma \log |G|.$$  

As $\log |S| \leq (1 - \varepsilon) \log |G|$, we deduce

$$(1 + \gamma) \log |\prod_{2m+2} S| \geq \log |S| + \frac{\gamma}{1-\varepsilon} \log |S| \geq (1 + \gamma) \log |S| + \gamma \varepsilon \log |S|.$$  

Hence by [19, Lemma 2.2], we get

$$(1 + \gamma)(2^{m+2} - 2)(\log |\prod_{3} S| - \log |S|) \geq (1 + \gamma)(\log |\prod_{2m+2} S| - \log |S|) \geq \gamma \varepsilon \log |S|;$$  

and the claim follows.

5 SUPER-APPROXIMATION: PROOF OF THEOREM 1

As it has been pointed out by Bradford (see [7, Theorem 1.14]) Varjú has already proved a multi-scale version of Bourgain–Gamburd’s result which in combination with Proposition 33 can be formulated as follows (see [48, Sections 3 and 5]).
**Theorem 58.** Suppose $L$ is a positive integer, $\delta_0 : \mathbb{R}^+ \to \mathbb{R}^+$, and $\{G_i\}_{i=1}^\infty$ is a family of finite groups that satisfy $V(1)_L - V(3)_L$ and $V(4)_{\delta_0}$. Suppose $\Omega$ is a symmetric generating set of $G := \bigoplus_{i=1}^n G_i$. Suppose there are $\eta > 0$, $C_0$, and $l < C_0 \log |G|$ such that for any proper subgroup $H$ of $G$, we have $P_{\pi_f^L}(H) \leq [G : H]^{-\eta}$. Then

$$1 - \lambda(P_{\pi_f^L};G) \gg L, \delta_0, \eta, C_0, |\Omega| 1.$$

Let us recall that by the discussion in Subsection 2.1, we can and will assume

$$\pi_f(G) \simeq \bigoplus_{\ell | f, \ell \text{ irred.}} G_{\ell}(K(\ell)), \quad \text{(85)}$$

where $K(\ell)$ is the finite field $\mathbb{F}_{p_0}[t]/(\ell)$, $G_{\ell}$ is an absolutely almost simple, simply connected, $K(\ell)$-group, and the absolute type of all the functions $G_{\ell}$ are the same.

By Proposition 6, there is a finite symmetric subset $\Omega'$ of $\Gamma$, a square-free polynomial $r_1$, and positive numbers $c_0$ and $\delta$ such that for any $f \in S_{r_1,c_0}$ (that means $f$ and $r_1$ are coprime and the degree of any irreducible factor of $f$ does not have a prime factor less than $c_0$), any purely structural subgroup $H$ of $\pi_f(G)$ and $l \gg \Omega \deg f$, we have

$$\pi_f(\langle \Omega' \rangle) = \pi_f(\Gamma), \quad \text{and} \quad P_{\pi_f(\Omega')}^{(l)}(H) \leq [\pi_f(\Gamma) : H]^{-\delta}; \quad \text{(86)}$$

moreover $\Omega' = \Omega'_0 \cup \Omega'_{0^{-1}}$ and $\Omega'_0$ freely generates a subgroup of $\Gamma$. By (86), to prove Theorem 1, it is enough to prove

$$1 - \lambda(P_{\pi_f(\Omega')};\pi_f(\Gamma)) \gg \Omega 1.$$

By (85), (86), and Theorem 58, to prove Theorem 1, it is enough to prove the following.

1. There are $L$ and $\delta_0$ such that $G_{\ell}(K(\ell))$ satisfies $V(1)_L - V(3)_L$, and $V(4)_{\delta_0}$ if $\ell$ is an irreducible polynomial that does not divide $r_1$.
2. There are $\eta > 0$, $C_0$, and $c_0' \geq c_0$ such that for any $f \in S_{r_1,c_0'}$ and any proper subgroup $H$ of $\pi_f(\Gamma)$ we have $P_{\pi_f(\Omega')}^{(l)}(H) \leq [\pi_f(\Gamma) : H]^{\eta}$ for some $l < C_0 \deg f$.

In the rest of this section, we will prove these items.

### 5.1 Verifying Varjú’s assumptions $V(1)_L - V(3)_L$, and $V(4)_{\delta_0}$ for $G_{\ell}(K(\ell))$

Since the functions $G_{\ell}$ are absolutely almost simple, simply connected, $K(\ell)$-groups, and all of them have the same absolute type, by [27], they satisfy $V(1)_L$ and $V(2)_L$ for some positive integer $L$. By the groundbreaking results [9, Corollary 2.4; 37, Theorem 4], there is a function $\delta_0$ such that the functions $G_{\ell}(K(\ell))$ satisfy $V(4)_{\delta_0}$. Now we introduce the families of subgroups $H_l$ and $H'_l$, and prove that they satisfy $V(3)_L$ for some positive integer $L$ that is independent of irreducible polynomials $\ell$.  

By Theorem 22, for a structural subgroup \( H \) of \( G_\ell(K(\ell)) \), there is a proper subgroup \( \mathbb{H} \) of \( G_\ell \) with complexity \( O_\Gamma(1) \) such that \( H \subseteq \mathbb{H}(K(\ell)) \). Since the complexity of \( \mathbb{H} \) is \( O_\Gamma(1) \), \( \mathbb{H}^0(K(\ell)) \) is bounded by a function of \( \Gamma \), where \( \mathbb{H}^0 \) is the connected component of the identity of \( \mathbb{H} \) in the Zariski topology. For \( 0 \leq i < \dim G \), initially we let

\[
H_i := \{ \mathbb{H}(K(\ell)) \mid \mathbb{H} \leq G_\ell, \dim \mathbb{H} = i, \mathbb{H} = \mathbb{H}^0 \text{, its complexity is bounded as above} \}
\]

Next for smaller dimension subgroups, we allow slightly larger complexity to include the connected components of the intersections of larger dimension connected proper subgroups. Then by Theorem 22, a subgroup \( H \) of \( G_\ell(K(\ell)) \) is a structural subgroup if and only if there is \( H^\sharp \) in \( H_i \) for some \( i \) such that \( H \leq H^\sharp \subseteq L \) where \( L := O_\Gamma(1) \). Moreover, the functions \( H_i \) satisfy the condition (V3)\(_L\)–(i)–(ii).

By Theorem 22, we know that if \( H \) is a proper subgroup of subfield type of \( G_\ell(K(\ell)) \), then there is a subfield \( F_H \) and an \( F_H \)-model \( G_H \) of \( \text{Ad}(G_\ell) \) such that

\[
[\text{Ad}(G_H(F_H)), \text{Ad}(G_H(F_H))] \subseteq \text{Ad}(H) \subseteq G_H(F_H).
\]

This implies that \( H \leq G_H(F_H) \) where \( G_H \) is a simply connected cover of \( G_H \).

**Lemma 59.** For a subgroup \( H \) of \( G_\ell(K(\ell)) \), let \( \text{Con}(H) \) be the set of all the conjugates of \( H \) in \( G_\ell(K(\ell)) \). For a subfield \( F \) of \( K(\ell) \), let

\[
n_F := |\{ \text{Con}(\tilde{G}(F)) \mid \tilde{G} \text{ is an } F \text{-model of } G_\ell \}|.
\]

Then \( n_F \ll_\mathbb{G} 1 \).

**Proof.** Since \( \tilde{G} \) has the same absolute type as \( G_\ell \), up to \( F \)-isomorphism there are only two choices; either \( \tilde{G} \) is the unique simply connected \( F \)-split group of the given absolute type or it is the unique quasi-split outer form of the given absolute type defined over \( F \). So without loss of generality, we fix an \( F \)-model \( \tilde{G}_0 \) of \( G_\ell \) and we want to show that

\[
|\{ \text{Con}(\tilde{G}(F)) \mid \tilde{G} \cong \tilde{G}_0 \text{ as } F \text{-groups} \}| \ll_\mathbb{G} 1.
\]

Note that if \( \tilde{G} \) is an \( F \)-model of \( G_\ell \) which is \( F \)-isomorphic to \( \tilde{G}_0 \), then there is an \( F \)-isomorphism \( \phi : \tilde{G}_0 \cong \tilde{G} \) which induces a automorphism of \( G_\ell \) after base change. Since \( [\text{Aut}(G_\ell) : \text{Ad}(G_\ell)] \ll 1 \), without loss of generality we can and will assume that \( \phi \) induces and inner automorphism of \( G_\ell \). Hence, we can and will assume that there is \( g \in G_\ell(K(\ell)) \) such that \( g\tilde{G}_0(F)g^{-1} = \tilde{G}(F) \subseteq \tilde{G}_0(K(\ell)). \) Therefore by Proposition 23, \( \text{Ad}(g) \in \text{Ad}(\tilde{G}_0)(K(\ell)) = \text{Ad}(G_\ell)(K(\ell)). \) Since \( [\text{Ad}(G_\ell)(K(\ell)) : \text{Ad}(G_\ell(K(\ell)))] \ll_\mathbb{G} 1 \), the claim follows.

We let the functions \( H'_i \) be the sets of conjugacy classes of the groups of the form \( \tilde{G}(F) \) where \( F \) is a proper subfield of \( K(\ell) \) and \( \tilde{G} \) is an \( F \)-model of \( G_\ell \). By Lemma 59, there are at most \( L \log |G_\ell(K(\ell))| \) where \( L \) just depends on the absolute type of the functions \( G_\ell \). By Corollary 25, the functions \( H'_i \) satisfy property (V3)\(_L\)–(v); and our claim follows.
5.2 Escaping proper subgroups

The main goal of this short section is to show that Proposition 6 is good enough to show the needed escaping from an arbitrary proper subgroup of $\pi_f(\Gamma)$ for $f \in S_{r_1,c_0}$.

**Lemma 60.** In the setting described at the beginning of Section 5, there are $\eta > 0$, $C_0$, and $c'_0 \geq c_0$ such that for any $f \in S_{r_1,c'_0}$ and any proper subgroup $H$ of $\pi_f(\Gamma)$ we have

$$P_{\pi_f(\Omega')}^{(2l)}(H) \leq [\pi_f(\Gamma) : H]^{-\eta}$$

for some $l < C_0 \deg f$.

**Proof.** We assume that $f \in S_{r_1,c'_0}$ for a sufficiently large $c'_0 \geq c_0$ (to be specified later). We split the set of irreducible divisors of $f$ into three disjoint sets:

- $D_1(f; H) := \{\ell | f \text{ s.t. } \ell \text{ is irreducible, } \pi_\ell(H) \text{ is a structural subgroup}\}$,
- $D_2(f; H) := \{\ell | f \text{ s.t. } \ell \text{ is irreducible, } \pi_\ell(H) \text{ is a subfield type subgroup}\}$, and
- $D_3(f; H) := \{\ell | f \text{ s.t. } \ell \text{ is irreducible, } \pi_\ell(H) = \pi_\ell(\Gamma)\}.$

Let $f_i := \prod_{\ell \in D_i(f; H)} \ell$ and $H_i := \prod_{\ell \in D_i(f; H)} \pi_\ell(H)$; then by Lemma 26 we have that

$$[\pi_{f_1}(\Gamma) : H_1][\pi_{f_2}(\Gamma) : H_2] = [\pi_f(\Gamma) : H_1 \oplus H_2 \oplus H_3] \geq [\pi_f(\Gamma) : H]^{1/L}. \quad (87)$$

By Proposition 6, we have

$$P_{\pi_{f_1}(\Omega')}^{(2l)}(H_1) \leq [\pi_{f_1}(\Gamma) : H_1]^{-\delta_0}, \quad (88)$$

where $\delta_0$ is a positive number which just depends on $\Omega$. On the other hand, by Kesten’s result on random walks in a free group (see [24, Theorem 3]), we have that, for some $c_1 > 0$, we have

$$\|P_{\pi_{f_2}(\Omega')}^{(2l_0)}\|_\infty \leq |\pi_{f_1}(\Gamma)|^{-c_1};$$

and so

$$P_{\pi_{f_2}(\Omega')}^{(2l_0)}(H_2) \leq |\pi_{f_1}(\Gamma)|^{-c_1} |H_2| \leq |\pi_{f_1}(\Gamma)|^{-c_1} \prod_{\ell' \not\in f_2, \text{irr.}} |\pi_{\ell'}(H_2)| \leq |\pi_{f_1}(\Gamma)|^{-c_1} |\pi_{f_2}(\Gamma)|^{1/c'_0}. \quad (89)$$

So if $c'_0 > 2/c_1$, then by (89) implies that

$$P_{\pi_{f_2}(\Omega')}^{(2l_0)}(H_2) \leq |\pi_{f_1}(\Gamma)|^{-c_1/2}. \quad (90)$$
By (90) and the fact that $\Omega'$ is a symmetric set, we have $P_{\pi f_2(\Omega')}^{(l_0)}(gH_2) \leq |\pi f_1(\Gamma)|^{-c_1/4}$; and so for any $l \geq l_0$, we have

$$P_{\pi f_2(\Omega')}^{(l)}(H) \leq |\pi f_1(\Gamma)|^{-c_1/4}. \quad (91)$$

By (88) and (91), we deduce that

$$P_{\pi f(\Omega')}^{(2l)}(H) \leq \min(P_{\pi f_1(\Omega')}^{(2l)}(H_1), P_{\pi f_2(\Omega')}^{(2l)}(H_2))$$

$$\leq (P_{\pi f_1(\Omega')}^{(2l)}(H_1) P_{\pi f_2(\Omega')}^{(2l)}(H_2))^{1/2}$$

$$\leq |\pi f_1 f_2(\Gamma)|^{-\min(\delta_0, c_1/4)} \leq [\pi f(\Gamma) : H_1 \oplus H_2 \oplus H_3]^{-\min(\delta_0, c_1/4)}. \quad (92)$$

By (87) and (92), we get

$$P_{\pi f(\Omega')}^{(2l)}(H) \leq [\pi f(\Gamma) : H]^{-\min(\delta_0/L, c_1/(4L))},$$

and the claim follows.

\[\Box\]

**ACKNOWLEDGEMENTS**

We would like to thank P. Varjú and M. Larsen for their quick replies to our questions in regard to their works. The second author is thankful to A. Mohammadi for many mathematical discussions related (and unrelated) to random walks in compact groups. We would like to thank the referee for their suggestions. A. Salehi Golsefidy was partially supported by the NSF grants DMS-1303121, DMS-1602137, DMS-1902090, and A. P. Sloan Research Fellowship. A. Salehi Golsefidy would like to thank the IAS for its hospitality; part of this work was done while A. Salehi Golsefidy was visiting the IAS. This article contains the main results proved in B. Longo’s PhD thesis which was done in the UCSD.

**JOURNAL INFORMATION**

The *Journal of the London Mathematical Society* is wholly owned and managed by the London Mathematical Society, a not-for-profit Charity registered with the UK Charity Commission. All surplus income from its publishing programme is used to support mathematicians and mathematics research in the form of research grants, conference grants, prizes, initiatives for early career researchers and the promotion of mathematics.
