On semiregularity of mappings

R. Cibulka¹, M. Fabian², A. Y. Kruger³

January 11, 2019

Abstract. There are two basic ways of weakening the definition of the well-known metric regularity property by fixing one of the points involved in the definition. The first resulting property is called metric subregularity and has attracted a lot of attention during the last decades. On the other hand, the latter property which we call semiregularity can be found under several names and the corresponding results are scattered in the literature. We provide a self-contained material gathering and extending the existing theory on the topic. We demonstrate a clear relationship with other regularity properties, for example, the equivalence with the so-called openness with a linear rate at the reference point is shown. In particular cases, we derive necessary and/or sufficient conditions of both primal and dual type. We illustrate the importance of semiregularity in the convergence analysis of an inexact Newton-type scheme for generalized equations with not necessarily differentiable single-valued part.

Key Words. open mapping theorem, linear openness, metric semiregularity, set-valued perturbation

AMS Subject Classification (2010) 49J53, 49J52, 49K40, 90C31.

1 Introduction

The concept of regularity of a set-valued mapping \( F \) acting from a metric space \((X, d)\) into (subsets of) another metric space \((Y, \varrho)\), denoted by \( F : X \rightrightarrows Y \), around a given reference point \((\bar{x}, \bar{y})\) in its graph \( \text{gph} F \) plays a fundamental role in modern variational analysis and non-smooth optimization, see, for example, a recent survey [19] by Ioffe or books [4, 13, 24, 34]. By regularity we mean that one of the three equivalent properties - metric regularity, openness with a linear rate around the reference point, and pseudo-Lipschitz property\(^4\) of the inverse \( F^{-1} \) - holds for the mapping under consideration. First, the mapping \( F \) is said to be metrically regular\(^5\) around \((\bar{x}, \bar{y})\) when \( \bar{y} \in F(\bar{x}) \) and there is a constant \( \kappa > 0 \) along with a neighborhood \( U \times V \) of \((\bar{x}, \bar{y})\) in \( X \times Y \) such that

\[
\text{dist} \left( x, F^{-1}(y) \right) \leq \kappa \text{dist} \left( y, F(x) \right) \quad \text{for every} \quad (x, y) \in U \times V,
\]

\(^4\)Often also called Lipschitz-like or Aubin property.

\(^5\)In [13], this property is called metric regularity at \( \bar{x} \) for \( \bar{y} \) under an additional assumption that the graph of \( F \) is locally closed at the reference point.
where dist\((u, C)\) is the distance from a point \(u\) to a set \(C\) and the space \(X \times Y\) is equipped with the product (box) topology. The infimum of \(\kappa > 0\) for which there exists a neighborhood \(U \times V\) of \((\bar{x}, \bar{y})\) in \(X \times Y\) such that (1) holds is called the regularity modulus of \(F\) around \((\bar{x}, \bar{y})\) and is denoted by \(\text{reg} F(\bar{x}, \bar{y})\).

Second, the mapping \(F\) is called open with a linear rate\(^6\) around \((\bar{x}, \bar{y})\) when \(\bar{y} \in F(\bar{x})\) and there are positive constants \(c\) and \(\varepsilon\) along with a neighborhood \(U \times V\) of \((\bar{x}, \bar{y})\) in \(X \times Y\) such that
\[
(2) \quad B[y, ct] \subset F(B[x, t]) \quad \text{whenever} \quad (x, y) \in U \times V, \quad y \in F(x) \quad \text{and} \quad t \in (0, \varepsilon),
\]
where \(B[u, r]\) denotes the closed ball centered at \(u\) with a radius \(r > 0\). The supremum of \(c > 0\) for which there exist a constant \(\varepsilon > 0\) and a neighborhood \(U \times V\) of \((\bar{x}, \bar{y})\) in \(X \times Y\) such that (2) holds is called the modulus of surjection of \(F\) around \((\bar{x}, \bar{y})\) and is denoted by \(\text{sur} F(\bar{x}, \bar{y})\). Finally, the mapping \(F : X \Rightarrow Y\) is said to be pseudo-Lipschitz around \((\bar{x}, \bar{y})\) when \(\bar{y} \in F(\bar{x})\) and there is a constant \(\mu > 0\) along with a neighborhood \(U \times V\) of \((\bar{x}, \bar{y})\) in \(X \times Y\) such that
\[
(3) \quad \text{dist} (y, F(x)) \leq \mu d(x, x') \quad \text{whenever} \quad x, x' \in U \quad \text{and} \quad y \in F(x') \cap V.
\]
The infimum of \(\mu > 0\) for which there exists a neighborhood \(U \times V\) of \((\bar{x}, \bar{y})\) in \(X \times Y\) such that (3) holds is called the Lipschitz modulus of \(F\) around \((\bar{x}, \bar{y})\) and is denoted by \(\text{lip} F(\bar{x}, \bar{y})\).

A fundamental well-known fact is that
\[
(4) \quad \text{sur} F(\bar{x}, \bar{y}) \cdot \text{reg} F(\bar{x}, \bar{y}) = 1 \quad \text{and} \quad \text{reg} F(\bar{x}, \bar{y}) = \text{lip} F^{-1}(\bar{y}, \bar{x}),
\]
under the convention that \(0 \cdot \infty = \infty \cdot 0 = 1\), \(\inf \emptyset = \infty\), and, as we work with nonnegative quantities, that \(\sup \emptyset = 0\).

Fixing one of the components of \((x, y)\) in (1), that is letting either \(x := \bar{x}\) or \(y := \bar{y}\), one gets two different, weaker than regularity, concepts. Of course, one can reformulate both of them in terms of openness and continuity of the inverse, respectively.

**Definition 1.1.** Consider a mapping \(F : X \Rightarrow Y\) between metric spaces \((X, d)\) and \((Y, \varrho)\) and a point \((\bar{x}, \bar{y}) \in X \times Y\).

\(\text{(A1)}\) \(F\) is said to be metrically subregular at \((\bar{x}, \bar{y})\) when \(\bar{y} \in F(\bar{x})\) and there is a constant \(\kappa > 0\) along with a neighborhood \(U\) of \(\bar{x}\) in \(X\) such that
\[
(5) \quad \text{dist} (x, F^{-1}(\bar{y})) \leq \kappa \text{dist} (\bar{y}, F(x)) \quad \text{for every} \quad x \in U.
\]
The infimum of \(\kappa > 0\) for which there exists a neighborhood \(U\) of \(\bar{x}\) in \(X\) such that (5) holds is called the subregularity modulus of \(F\) at \((\bar{x}, \bar{y})\) and is denoted by \(\text{subreg} F(\bar{x}, \bar{y})\);

\(\text{(A2)}\) \(F\) is said to be pseudo-open with a linear rate at \((\bar{x}, \bar{y})\) when \(\bar{y} \in F(\bar{x})\) and there are positive constants \(c\) and \(\varepsilon\) along with a neighborhood \(U\) of \(\bar{x}\) in \(X\) such that
\[
(6) \quad \bar{y} \in F(B[\bar{x}, t]) \quad \text{whenever} \quad x \in U \cap F^{-1}(B[\bar{y}, ct]) \quad \text{and} \quad t \in (0, \varepsilon).
\]
The supremum of \(c > 0\) for which there exist a constant \(\varepsilon > 0\) and a neighborhood \(U\) of \(\bar{x}\) in \(X\) such that (6) holds is called the modulus of pseudo-openness of \(F\) at \((\bar{x}, \bar{y})\) and is denoted by \(\text{popen} F(\bar{x}, \bar{y})\);

\(^6\)There are other equivalent definitions in the literature. Also note that in [13] the constant \(c\) appears on the right-hand side of (2).

\(^7\)Clearly, we can replace the closed balls in (2) with the opens.
(A3) $F$ is said to be calm at $(\bar{x}, \bar{y})$ when $\bar{y} \in F(\bar{x})$ and there is a constant $\mu > 0$ along with a neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$ such that

$$(7) \quad \text{dist} (y, F(\bar{x})) \leq \mu d(\bar{x}, x) \quad \text{whenever} \quad x \in U \quad \text{and} \quad y \in F(x) \cap V.$$  

The infimum of $\mu > 0$ for which there exists a neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$ such that (7) holds is called the calmness modulus of $F$ at $(\bar{x}, \bar{y})$ and is denoted by calm $F(\bar{x}, \bar{y})$.

Properties in (A1) and (A3) are entrenched in the literature [34, 13] and the metric subregularity of a mapping is known to be equivalent to the calmness of its inverse. (A2) is defined and proved to be equivalent with the remaining ones in [2]. More precisely, the following analogue of (4) holds true

$$(8) \quad \text{popen} F(\bar{x}, \bar{y}) \cdot \text{subreg} F(\bar{x}, \bar{y}) = 1 \quad \text{and} \quad \text{subreg} F(\bar{x}, \bar{y}) = \text{calm} F^{-1}(\bar{y}, \bar{x}).$$

The case when $x := \bar{x}$ in (11), being the same as letting $(x, y) := (\bar{x}, \bar{y})$ in (2), is known under several names. In this note we provide a self-contained material gathering and extending results on this property scattered in the literature and illustrate possible applications.

**Definition 1.2.** Consider a mapping $F : X \Rightarrow Y$ between metric spaces $(X, d)$ and $(Y, \rho)$ and a point $(\bar{x}, \bar{y}) \in X \times Y$.

(B1) $F$ is said to be metrically semiregular at $(\bar{x}, \bar{y})$ when $\bar{y} \in F(\bar{x})$ and there is a constant $\kappa > 0$ along with a neighborhood $V$ of $\bar{y}$ in $Y$ such that

$$(9) \quad \text{dist} (\bar{x}, F^{-1}(y)) \leq \kappa \rho(\bar{y}, y) \quad \text{for every} \quad y \in V.$$  

The infimum of $\kappa > 0$ for which there exists a neighborhood $V$ of $\bar{y}$ in $Y$ such that (9) holds is called the semiregularity modulus of $F$ at $(\bar{x}, \bar{y})$ and is denoted by semireg $F(\bar{x}, \bar{y})$;

(B2) $F$ is said to be open with a linear rate at $(\bar{x}, \bar{y})$ when $\bar{y} \in F(\bar{x})$ and there are positive constants $c$ and $\varepsilon$ such that

$$(10) \quad B[\bar{y}, ct] \subset F(B[\bar{x}, t]) \quad \text{for each} \quad t \in (0, \varepsilon).$$  

The supremum of $c > 0$ for which there exists a constant $\varepsilon > 0$ such that (10) holds is called the modulus of openness of $F$ at $(\bar{x}, \bar{y})$ and is denoted by lopen $F(\bar{x}, \bar{y})$.

Properties (B1) and (B2) were studied by the third author in [30] (see also [32]), where their equivalence was established (see Proposition 2.1 below) and the term semiregularity was suggested for property (B1). This property has been later used in [3, 14, 38] under the name hemiregularity. Following [10], property (B2) was referred to in [30] as $c$-covering, while in the earlier paper [29] it was called simply regularity. This property can be found also in [14, 13]. In the recent survey by Ioffe [19], the property is called controllability, the concept stemming from the control theory. The explicit definition of lopen $F(\bar{x}, \bar{y})$ can be found in [27, 28], while its main components are present already in [25, 26]. Note that thanks to the Robinson-Ursescu theorem, if $F$ has a closed convex graph, the openness (with a linear rate) at a point is equivalent to the openness around this point.

One can define the third (equivalent) property in terms of the inverse $F^{-1}$. To the best of our knowledge, it first appeared in [24, p. 34] under the name Lipschitz lower semicontinuity. It was
defined for $F^{-1}$ via inequality (9). This property is called pseudo-calmness in [14], while the term linear recession is used in [19].

A (graphical) localization of a set-valued mapping $F : X \rightrightarrows Y$ around the reference point $(\bar{x}, \bar{y}) \in \text{gph} F$ is any mapping $\tilde{F} : X \rightrightarrows Y$ such that $\text{gph } \tilde{F} = \text{gph } F \cap (U \times V)$ for some neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$. Using this notion we can define “stronger” versions of the properties mentioned above.

Definition 1.3. Consider a mapping $F : X \rightrightarrows Y$ between metric spaces $(X, d)$ and $(Y, g)$ and a point $(\bar{x}, \bar{y}) \in X \times Y$. Then $F$ is said to be

(S) strongly metrically regular around $(\bar{x}, \bar{y})$ when $F$ is metrically regular at $(\bar{x}, \bar{y})$ and $F^{-1}$ has a localization around $(\bar{y}, \bar{x})$ which is nowhere multivalued;

(SA) strongly metrically subregular at $(\bar{x}, \bar{y})$ when $F$ is metrically subregular at $(\bar{x}, \bar{y})$ and $F^{-1}$ has no localization around $(\bar{y}, \bar{x})$ that is multivalued at $\bar{y}$;

(SB) strongly metrically semiregular at $(\bar{x}, \bar{y})$ when $F$ is metrically semiregular at $(\bar{x}, \bar{y})$ and $F^{-1}$ has a localization around $(\bar{y}, \bar{x})$ which is nowhere multivalued.

Clearly, (S)–(SA) are connected with (and can be defined by) the properties of the inverse $F^{-1}$. Indeed, (S) means that for each $\ell > \text{reg } F(\bar{x}, \bar{y})$ there is a neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$ such that the localization $V \ni y \mapsto F^{-1}(y) \cap U$ is single-valued and Lipschitz continuous on $V$ with the constant $\ell$ [13 Proposition 3G.1]. While (SA) means that for each $\ell > \text{subreg } F(\bar{x}, \bar{y})$ there is a neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$ such that

$$d(\bar{x}, x) \leq \ell g(\bar{y}, y) \quad \text{whenever } x \in U \text{ and } y \in F(x) \cap V.$$ 

Finally, (SB) means that for each $\ell > \text{semireg } F(\bar{x}, \bar{y})$ there is a neighborhood $U \times V$ of $(\bar{x}, \bar{y})$ in $X \times Y$ such that the localization $V \ni y \mapsto F^{-1}(y) \cap U$ is single-valued and calm on $V$ with the constant $\ell$. As in the case of regularity, we omit the word “metrically” in the rest of the note, that is, we say that $F$ is subregular (semiregular, strongly regular, etc.) at/around $(\bar{x}, \bar{y})$.

Note that the validity of both the weaker point-based properties does not imply the stronger one, that is, if $F$ satisfies (A1) and (B1) then $F$ does not need to be regular around the reference point (see Example 2.3).

Now, we survey several well known results concerning regularity and (sub)regularity which are related to the ones presented in this note. Let us point out that in case of a single-valued mapping, denoted by $f : X \to Y$, we do not mention the point $\bar{y} = f(\bar{x})$ in all the above definitions, that is, we write sur $f(\bar{x})$, reg $f(\bar{x})$, etc., instead of sur $f(\bar{x}, f(\bar{x}))$, reg $f(\bar{x}, f(\bar{x}))$, etc.; and if the corresponding modulus is independent of $\bar{x}$ then we omit $\bar{x}$ as well.

Suppose that $X$ and $Y$ are Banach spaces and $A : X \to Y$ is a continuous linear operator. Then the Banach-Schauder open mapping theorem and the linearity of $A$ imply (cf. [34 Theorem 1.104 and Proposition 1.106], [3 Proposition 5.2]) that: $A$ is regular around any point $\iff A$ is semiregular at any point $\iff A$ is surjective; moreover

$$\text{semireg } A = \text{reg } A \quad \text{and} \quad \text{sur } A = \sup \{ \rho > 0 : A(B_X) \supset \rho B_Y \} = \inf \{ \| A^* y^* \| : y^* \in S_{Y^*} \},$$

where $A^*$ is the adjoint (dual) operator to $A$ acting between the dual spaces $Y^*$ and $X^*$ of $Y$ and $X$, and $B_Z$ and $S_Z$ denote the closed unit ball and the unit sphere in a normed space $Z$, respectively.
This is a particular case of Proposition 2.2 (iv). If \( A \) is invertible, then \( \text{sur } A = 1/\|A^{-1}\| \). For a real \( m \)-by-\( n \) matrix \( A \in \mathbb{R}^{m \times n} \), \( \text{sur } A \) equals to the least singular value of \( A \). Using the Banach-Schauder theorem again, if \( A \) has closed range, then it is subregular at any point; and if, in addition, \( A \) is injective then it is strongly subregular everywhere. Note that both the statements fail without the closedness assumption (see \([8\) Example 2.7\)). In general, \( A \) is strongly subregular everywhere if and only if \( \kappa := \inf_{h \in \mathbb{S}_X} \|Ah\| > 0 \); moreover \( \text{subreg} A = 1/\kappa \). If the dimension of \( X \) is finite, then \( \kappa > 0 \) if and only if \( A^{-1}(0) = \{0\} \), that is, \( A \) is injective.

Using the above notation, for a non-linear mapping we have the following result:

**Theorem 1.4.** Consider a mapping \( f : X \to Y \) defined around a point \( \bar{x} \in X \) and a continuous linear mapping \( A : X \to Y \).

(i) Then \( \text{sur } f(\bar{x}) \geq \text{sur } A - \text{lip}(f - A)(\bar{x}) \). If, in addition, the mapping \( A \) is invertible and \( \text{lip}(f - A)(\bar{x}) < \text{sur } A \), then \( f \) is strongly regular at \( \bar{x} \) and \( \text{sur } A \geq 1/\|A^{-1}\| - \text{lip}(f - A)(\bar{x}) ( > 0) \).

(ii) If \( A \) is strongly subregular (everywhere) and \( \text{calm}(f - A)(\bar{x}) < \text{popen } A \), then \( f \) is strongly subregular at \( \bar{x} \) and \( \text{popen } f(\bar{x}) \geq \text{popen } A - \text{calm}(f - A)(\bar{x}) ( > 0) \).

**Theorem 1.4** is a particular case of the well known fact that (strong) regularity as well as strong subregularity are stable with respect to a single-valued perturbation (see Theorem 1.3 below). Part (i) was proved by Graves \([16\] and Graves-Hildebrand \([17\]. More precisely, Graves proved that \( \text{popen } f(\bar{x}) \geq \text{sur } A - \text{lip}(f - A)(\bar{x}) > 0 \), which is weaker. As observed in \([11\]) a slight modification of the original proof yields the (stronger) version above. If \( A \) is the strict derivative of \( f \) at \( \bar{x} \), that is, when \( \text{lip}(f - A)(\bar{x}) = 0 \), then we have \( \text{sur } f(\bar{x}) = \text{sur } A \). This is the case, for example, if \( f \) is (Gateaux) differentiable in a vicinity of \( \bar{x} \) and the derivative mapping \( x \mapsto Df(x) \) is continuous at \( \bar{x} \) as a mapping from \( X \) into \( L(X,Y) \), the space of all linear bounded operators from \( X \) into \( Y \). In fact, the weak Gateaux differentiability is enough. In particular, the Lyusternik theorem \([33\], proved before the Graves theorem, follows from Theorem 1.4. On the other hand, assume that \( X := \mathbb{R}^n \) and \( Y := \mathbb{R}^m \). If \( f \) is strictly differentiable at \( \bar{x} \), then there is a neighborhood \( U \) of \( \bar{x} \) such that \( f \) is Lipschitz continuous on \( U \). Let \( D \subset U \) be the set of all \( x \in U \) such that \( f \) is Fréchet differentiable at \( x \). Then \( D \) has full Lebesgue measure by the Rademacher theorem. Moreover, the Jacobian mapping \( D \ni x \mapsto \nabla f(x) \in \mathbb{R}^{m \times n} \) is continuous at \( \bar{x} \) \([35\], Lemma 5.1\]. However, this does not imply that \( f \) is differentiable on any neighborhood of \( \bar{x} \) \([35\] p. 324 or \([13\, p.35\])\). If \( f \) is differentiable in a vicinity of \( \bar{x} \) then \( f \) is strictly differentiable at \( \bar{x} \) if and only if \( \nabla f \) is continuous at \( \bar{x} \) \([13\, Proposition 1D.7\]. Theorem 1.4 (ii) which can be found as \([8\, Theorem 2.1\], for example, fails when (non-strong) subregularity is considered \([13\, p. 201\].

To check the regularity of the mapping in question we have the following regularity criterion \([15\, Corollary 1\], [20\, Theorem 1b\], [9\, Proposition 2.1\].

**Proposition 1.5.** Let \((X,d)\) be a complete metric space and \((Y,g)\) be a metric space, let \( \bar{x} \in X \) be given, and let \( g : X \to Y \) be a continuous mapping, whose domain is all of \( X \). Then \( \text{sur } g(\bar{x}) \) equals to the supremum of all \( c > 0 \) for which there is \( r > 0 \) such that for all \((x,y) \in \mathbb{B}(\bar{x},r) \times (\mathbb{B}(g(\bar{x}),r) \setminus \{g(x)\}) \) there is a point \( x' \in X \) satisfying

\[ cd(x', x) < g(x, y) - g(g(x'), y). \]

\(^*\)Sometimes called strong derivative \([35\].
More precisely, Fabian and Preiss \cite{15} proved only a sufficient condition guaranteeing that \( \text{popen} g(\bar{x}) > 0 \). The full version (for set-valued mappings) was shown independently by Ioffe \cite{20}. As in the case of Theorem 1.4, only a tiny modification of the original proof from \cite{15} yields the statement above (see \cite{9}). Although Proposition 1.3 is formulated for a single-valued function, it is well-known that the study of regularity properties for a set-valued mapping \( F : X \rightrightarrows Y \) can always be reduced to the study of the corresponding property for a simple single-valued mapping, namely, the restriction of the canonical projection from \( X \times Y \) onto \( Y \), that is, the assignment \( \text{gph} F \ni (x, y) \mapsto y \in Y \) (e.g., see \cite{20} Proposition 3]). Using this, one gets the following statement for set-valued mappings.

**Theorem 1.6.** Let \((X, d)\) and \((Y, \rho)\) be metric spaces and let \( F : X \rightrightarrows Y \) be a set-valued mapping having a localization around \((\bar{x}, \bar{y}) \in \text{gph} F\) with a complete graph. Then \( \text{sur} F(\bar{x}, \bar{y}) \) equals to the supremum of all \( c > 0 \) for which there are \( r > 0 \) and \( \alpha \in (0, 1/c) \) such that for any \((x, v) \in \text{gph} F \cap (\mathcal{B}(\bar{x}, r) \times \mathcal{B}(\bar{y}, r))\) and any \( y \in \mathcal{B}(\bar{y}, r) \setminus \{v\}\) there is a pair \((x', v') \in \text{gph} F\) satisfying

\[
(12) \quad c \max\{d(x, x'), \alpha \rho(v, v')\} < \rho(v, y) - \rho(v', y).
\]

It is elementary to check that popen \( F(\bar{x}, \bar{y}) \) equals to the subregularity constant of \( F \) at \((\bar{x}, \bar{y})\) defined in \cite{31} as

\[
(13) \quad \liminf_{x \to \bar{x}} \frac{\text{dist}(\bar{y}, F(x))}{\text{dist}(\bar{x}, F^{-1}(\bar{y}))},
\]

with the convention that the limit in \((13)\) is \( \infty \) when \( \bar{x} \) is an internal point in \( F^{-1}(\bar{y}) \). When \( \bar{x} \) is an isolated point in \( F^{-1}(\bar{y}) \), then popen \( F(\bar{x}, \bar{y}) \) coincides with the steepest displacement rate at \((\bar{x}, \bar{y})\) defined by Uderzo in \cite{37} as

\[
(14) \quad |F|^+(\bar{x}, \bar{y}) := \liminf_{x \to \bar{x}} \frac{\text{dist}(\bar{y}, F(x))}{d(\bar{x}, x)},
\]

with the convention that the limit in \((14)\) is \( \infty \) when \( \bar{x} \) is an isolated point in the domain of \( F \). The inequality \( |F|^+(\bar{x}, \bar{y}) > 0 \) is equivalent to the strong subregularity of \( F \) at \((\bar{x}, \bar{y})\).

There is a similar statement to Theorem 1.6 guaranteeing the (strong) subregularity. The next theorem combines a portion of \cite{31} Corollary 5.8 (with condition (d)) and \cite{8} Theorem 5.3. The latter one was formulated in \cite{8} for Banach spaces, but its proof remains valid in the present setting.

**Theorem 1.7.** Let \((X, d)\) and \((Y, \rho)\) be metric spaces and let \( F : X \rightrightarrows Y \) be a set-valued mapping having a localization around \((\bar{x}, \bar{y}) \in \text{gph} F\) with a complete graph. Then popen \( F(\bar{x}, \bar{y}) \) (respectively, \( |F|^+(\bar{x}, \bar{y}) \)) equals to the supremum of \( c > 0 \) for which there exists \( r > 0 \) such that for any \((x, y) \in \text{gph} F\) with \( x \notin F^{-1}(\bar{y}) \) and \( d(x, \bar{x}) < r \) (respectively, \( 0 < d(x, \bar{x}) < r \)) and \( \rho(y, \bar{y}) < r \), there is a pair \((u, v) \in \text{gph} F \setminus \{(x, y)\}\) satisfying

\[
(15) \quad c \max\{d(u, x), r \rho(v, y)\} < \rho(y, \bar{y}) - \rho(v, \bar{y}).
\]

Note that (sufficient) conditions for (non-strong) subregularity and semiregularity are much more involved because of their instability with respect to calm (or Lipschitz) single-valued perturbations (see counterexamples \cite{13} pp. 200–201). More precisely, for these two properties, the analogues of the following statement (see \cite{13} Theorems 5E.1 and 5F.1 and \cite{8} Corollary 2.2) fail without additional assumptions.
Theorem 1.8. Let \((X, d)\) be a complete metric space, \((Y, \varrho)\) be a linear metric space with a shift-invariant metric, and \((\bar{x}, \bar{y}) \in X \times Y\). Consider a mapping \(g : X \to Y\) defined around \(\bar{x}\) and a mapping \(F : X \rightrightarrows Y\) such that \(\bar{y} \in F(\bar{x})\).

(i) If \(F\) is (strongly) regular around \((\bar{x}, \bar{y})\) and \(\text{lip}\,g(\bar{x}) < \text{sur}\,F(\bar{x}, \bar{y})\), then so is \(g + F\) around \((\bar{x}, g(\bar{x}) + \bar{y})\) and

\[
\text{sur}\,(g + F)(\bar{x}, g(\bar{x}) + \bar{y}) \geq \text{sur}\,F(\bar{x}, \bar{y}) - \text{lip}\,g(\bar{x}) > 0.
\]

(ii) If \(F\) is strongly subregular at \((\bar{x}, \bar{y})\) and \(\text{calm}\,g(\bar{x}) < \text{popen}\,F(\bar{x}, \bar{y})\), then so is \(g + F\) at \((\bar{x}, g(\bar{x}) + \bar{y})\) and

\[
\text{popen}(g + F)(\bar{x}, g(\bar{x}) + \bar{y}) \geq \text{popen}\,F(\bar{x}, \bar{y}) - \text{calm}\,g(\bar{x}) > 0.
\]

The above statement fails if a perturbation is set-valued (see [13, Example 5.1] and [8, p. 5]).

Regularity as well as strong (sub)regularity are known to play a key role in the local convergence analysis for Newton-type iterative schemes for solving a generalized equation, introduced by Robinson in [36], which reads as:

\[(16) \quad \text{Find } x \in X \text{ such that } f(x) + F(x) \ni 0,\]

where \(X\) and \(Y\) are (real) Banach spaces, \(f : X \to Y\) is a single-valued (possibly nonsmooth) mapping, and \(F : X \rightrightarrows Y\) is a set-valued mapping with closed graph. This model has been used to describe in a unified way various problems such as equations (when \(F \equiv 0\)), inequalities (when \(Y = \mathbb{R}^n\) and \(F \equiv \mathbb{R}^n\)), variational inequalities (when \(Y = X^*\) and \(F\) is the normal cone mapping corresponding to a closed convex subset of \(X\) or more broadly the subdifferential mapping of a convex function on \(X\)).

The Newton iteration for \((16)\) with a smooth function \(f\), also known as the Josephy-Newton method [23], has the form

\[(17) \quad f(x_k) + f'(x_k)(x_{k+1} - x_k) + F(x_{k+1}) \ni 0 \quad \text{for each } k \in \mathbb{N}_0 := \{0\} \cup \mathbb{N} \text{ and a given } x_0 \in X.\]

From the numerical point of view, it is clear that the auxiliary inclusions above cannot be solved exactly because of the finite precision arithmetic and rounding errors. Moreover, it can be much quicker to find an inexact solution at each step which has a sufficiently small residual. Various (in)exact methods were proposed in the literature (see [21] for an in-depth study and a vast bibliography, or [24] and references therein). In order to represent inexactness, Dontchev and Rockafellar proposed in [12] an inexact version of the iteration \((17)\) in which, for given \(k \in \mathbb{N}_0\) and \(x_k \in X\), the next iterate \(x_{k+1} \in X\) is determined as a coincidence point of the mapping on the left-hand side of \((17)\) and a mapping \(R_k : X \times X \rightrightarrows Y\) which models inexactness, that is,

\[(18) \quad (f(x_k) + f'(x_k)(x_{k+1} - x_k) + F(x_{k+1})) \cap R_k(x_k, x_{k+1}) \neq \emptyset.\]

Now, we describe the structure of our note in detail as well as the relation of the results presented and the existing ones. In Section 2 we recall that there is a clear link between semiregularity and openness at a point similar to \((\mathbb{1})\) and \((\mathbb{3})\). Next, we remark that, for particular mappings, semiregularity can imply regularity and that the corresponding moduli can be easily computed (as
in the case of a continuous linear operator). On the other hand, we provide examples illustrating the differences. Proposition 2.2(ii) slightly generalizes known results that the usual openness implies the linear openness under a certain “convexity” assumption on the graph of the mapping under consideration.

In Section 5, we discuss both primal and dual infinitesimal conditions. More precisely, new slope-based necessary as well as sufficient conditions are obtained (Theorem 5.1) and the dual necessary condition is recalled (Theorem 5.2). Theorem 5.3, which seems to be new, is a finite-dimensional analogue of Theorem 1.4 and its corollaries generalize existing results in one, in our opinion, very important direction for applications - the usual openness is strengthened to linear openness. We show that a similar approach yields a statement for set-valued mappings satisfying certain “strong monotonicity/ellipticity” assumptions (Theorem 5.4) and present corollaries correcting some statements from the literature (cf. Remark 5.10).

In Section 4, we prove general necessary as well as sufficient conditions in the spirit of Theorems 1.6 and 1.7, which are known to provide short and elegant proofs of various regularity statements in the literature [19, 9]. To prove set-valued versions of these conditions, we use theorems 1.6 and 1.7, which are known to provide short and elegant proofs of various regularity conditions. More precisely, new slope-based necessary as well as sufficient conditions are obtained (Theorem 3.1) and the dual necessary condition is recalled (Theorem 3.3). Theorem 3.4, which seems to be new, is a finite-dimensional analogue of Theorem 1.4 and its corollaries generalize existing results in one, in our opinion, very important direction for applications - the usual openness is strengthened to linear openness. We show that a similar approach yields a statement for set-valued mappings satisfying certain “strong monotonicity/ellipticity” assumptions (Theorem 5.4) and present corollaries correcting some statements from the literature (cf. Remark 5.10).

In Section 5, we analyze an inexact Newton-type iteration for the case when the function f in (16) is not necessarily differentiable. Specifically, we introduce a mapping \( \mathcal{H} : X \rightrightarrows \mathcal{L}(X, Y) \) viewed as a generalized set-valued derivative of the function f, and consider the following iteration: Given an index \( k \in \mathbb{N} \), and a point \( x_k \in X \), choose any \( A_k \in \mathcal{H}(x_k) \) and then find \( x_{k+1} \in X \) satisfying

\[
(f(x_k) + A_k(x_{k+1} - x_k) + F(x_{k+1})) \cap R_k(x_k, x_{k+1}) \neq \emptyset.
\]

Semiregularity of \( f(x_k) + A_k(\cdot - x_k) + F - R_k(x_k, \cdot) \) turns out to play a fundamental role in the existence of the next iterate close enough to the current one. The case when the mappings \( R_k \) depend on the current iterate \( x_k \) only, was studied in [7]. The proof of the convergence result is divided into two steps. Step 1 uses the classical statements and establishes uniformity of the assumed regularity, that is, that the constants and neighborhoods can be taken the same. The semiregularity of the sum is needed in Step 2 which, of course, can be done via a (complicated) double fixed-point theorem as in [12]. We show that the perturbation result is strong enough to obtain the conclusion (as in the usual case) obtaining in this way a completely different proof from [12].

**Notation and terminology.** When we write \( f : X \to Y \) we mean that f is a (single-valued) mapping acting from X into Y while \( F : X \rightrightarrows Y \) is a mapping from X into Y which may be set-valued. The set \( \text{dom} F := \{ x \in X : F(x) \neq \emptyset \} \) is the domain of F, the graph of F is the set \( \text{gph} F := \{(x, y) \in X \times Y : y \in F(x)\} \) and the inverse of F is the mapping \( Y \ni y \mapsto \{ x \in X : y \in F(x) \} =: F^{-1}(y) \subseteq X \); thus \( F^{-1} : Y \rightrightarrows X \). In any metric space, \( \mathcal{B}[x, r] \) denotes the closed ball centered at \( x \) with a radius \( r > 0 \) and \( \mathcal{B}(x, r) \) is the corresponding open ball. \( \mathcal{B}_X \) and \( S_X \) are respectively the closed unit ball and the unit sphere in a normed space X. The distance from a point \( x \) to a subset C of a metric space \( (X, d) \) is dist(\( x, C \)) := \inf\{d(x, y) : y \in C\}. We use the convention
that $\inf \emptyset := \infty$ and as we work with non-negative quantities we set $\sup \emptyset := 0$. If a set is a singleton we identify it with its only element, that is, we write $a$ instead of $\{a\}$. The symbol $\mathcal{L}(X,Y)$ denotes the space of all linear bounded operators from a Banach space $X$ into a Banach space $Y$. Then $\mathbb{R}^{m \times n} := \mathcal{L}(\mathbb{R}^m, \mathbb{R}^n)$ and $X^* := \mathcal{L}(X, \mathbb{R})$. Given $A \in \mathcal{L}(X,Y)$, the operator $A^* : Y^* \to X^*$ denotes the adjoint (dual, transpose) operator to $A$. The transpose of a matrix $A \in \mathbb{R}^{m \times n}$ is $A^T \in \mathbb{R}^{n \times m}$.

Given a set $A$ in $\mathcal{L}(X,Y)$, the measure of noncompactness $\chi(A)$ of $A$ is defined as

$$
\chi(A) := \inf \{ r > 0 : A \subset F + r \mathcal{B}_{\mathcal{L}(X,Y)} \text{ for some finite } F \subset A \}.
$$

Given an extended real-valued function $\varphi : X \to \mathbb{R} \cup \{\infty\}$ and a point $x \in X$, the limes inferior of $\varphi$ at $x$ is defined by

$$
\liminf_{u \to x} \varphi(u) := \sup_{r > 0} \inf_{u \in B(x,r)} \varphi(u).
$$

2 Relationship among regularity concepts

Let us start with a simple observation [14, Proposition 2.4] and [30, Theorem 6(i)]:

**Proposition 2.1.** Consider a mapping $F : X \rightrightarrows Y$ between metric spaces $(X,d)$ and $(Y,\varrho)$ and a point $(\bar{x},\bar{y}) \in \text{gph} F$. Then

$$
\text{lopen} F(\bar{x},\bar{y}) \cdot \text{semireg} F(\bar{x},\bar{y}) = 1.
$$

The relationship among various properties is summarized in the following statement:

**Proposition 2.2.** Consider a mapping $F : X \rightrightarrows Y$ between metric spaces $(X,d)$ and $(Y,\varrho)$ and a point $(\bar{x},\bar{y}) \in X \times Y$. Then

(i) $\text{lopen} F(\bar{x},\bar{y}) \geq \liminf_{(x,y) \to (\bar{x},\bar{y}), \ y \in F(x)} \text{lopen} F(x,y) \geq \text{sur} F(\bar{x},\bar{y})$.

(ii) Suppose that $X$ and $Y$ are normed spaces and that $F$ has a locally star-shaped graph at $(\bar{x},\bar{y})$, that is, there is $a \in (0,1]$ such that $(1-t)(\bar{x},\bar{y}) + t \text{gph} F \subset \text{gph} F$ for each $t \in [0,a]$. If there are positive constants $\alpha$ and $\beta$ such that

$$
\mathcal{B}[\bar{y}, \beta] \subset F(\mathcal{B}[\bar{x}, \alpha]),
$$

then $\text{lopen} F(\bar{x},\bar{y}) \geq \beta/\alpha$.

(iii) If $X$ and $Y$ are normed spaces and $F$ has a convex graph then $\text{lopen} F(\bar{x},\bar{y}) = \text{sur} F(\bar{x},\bar{y})$.

(iv) If $X$ and $Y$ are Banach spaces and $F$ is a closed convex process, that is, $\text{gph} F$ is a closed convex cone in $X \times Y$, then

$$
\text{lopen} F(0,0) = \text{sur} F(0,0) = \sup \{ \varrho > 0 : F(\mathcal{B}_X) \supset \varrho \mathcal{B}_Y \} = \inf \{ \|x^*\| : x^* \in F^*(\mathbb{S}_Y) \},
$$

where $F^* : Y^* \to X^*$ is the adjoint process to $F$ defined by

$$
F^*(y^*) = \{ x^* \in X^* : \langle x^*,x \rangle \leq \langle y^*,y \rangle \text{ for each } (x,y) \in \text{gph} F \}.
$$
Proof. Statement (i) follows immediately from the definitions of sur $F(\bar{x}, \bar{y})$ and the 
limes inferior, while (iv) is \cite[Theorem 7.9]{19}. Assume without any loss of 
generality that $\bar{x} = 0$ and $\bar{y} = 0$.

(ii) By assumption, there is $a \in (0, 1]$ such that $\tau F \subset \text{gph } F$ for each $\tau \in [0, a]$. Then (21) implies that

$$\tau \beta \mathcal{B}_Y \subset F(\tau \alpha \mathcal{B}_X) \quad \text{for each } \tau \in [0, a].$$

Indeed, fix any such $\tau$. Pick an arbitrary $y \in \tau \beta \mathcal{B}_Y$. Then $v := y/\tau \in \beta \mathcal{B}_Y$. By (21), there is $u \in X$ such that $v \in F(u)$ and $\|u\| \leq \alpha$. Then $x := \tau u \in \tau \alpha \mathcal{B}_X$. Moreover, $(x, y) = \tau (u, v) \in \tau gph F \subset gph F$. Thus $y \in F(x)$.

Set $c := \beta/\alpha$ and $\varepsilon := \alpha a$. Fix any $t \in (0, \varepsilon)$. Then $\tau := t/\alpha \in (0, a)$, and consequently,

$$F(t \mathcal{B}_X) = F(\tau \alpha \mathcal{B}_X) \supset \tau \beta \mathcal{B}_Y = ct \mathcal{B}_Y.$$ 

(iii) By (i), it suffices to show that $\text{lopen } F(0, 0) \leq \text{sur } F(0, 0)$. Fix arbitrary $c, \bar{c} \in (0, \text{lopen } F(0, 0))$ with $c < \bar{c}$. Find $\alpha \in (0, 1)$ such that $\bar{c} \alpha \mathcal{B}_Y \subset F(\alpha \mathcal{B}_X)$, and then $r > 0$ such that $c(\alpha + r) + r < \bar{c} \alpha$. Fix any $(x, y) \in \text{gph } F$ with $\|x\| \leq r$ and $\|y\| \leq r$. Then

$$\mathcal{B}[y, c(\alpha + r)] \subset (c(\alpha + r) + r) \mathcal{B}_Y \subset \bar{c} \alpha \mathcal{B}_Y \subset F(\alpha \mathcal{B}_X) \subset F(\mathcal{B}[x, \alpha + r]).$$

As in the proof of (ii), with $a := 1$, $\beta := c(\alpha + r)$, and $(\bar{x}, \bar{y}, \alpha)$ replaced by $(x, y, \alpha + r)$, we conclude that for any $t \in (0, \alpha + r)$ we have $\mathcal{B}[y, ct] \subset F(\mathcal{B}[x, t])$. Since $\alpha$ and $r$ are independent of $(x, y)$, we obtain that $\text{sur } F(0, 0) \geq c$. Letting $c \uparrow \text{lopen } F(0, 0)$ we get the desired estimate. \hfill \Box

To illustrate the difference between the regularity properties we provide the following examples.

**Example 2.3.** Consider a function $f : \mathbb{R} \to \mathbb{R}$ defined by

$$f(x) = \begin{cases} 
  x + \frac{x^3}{|x|} \left| \sin \left( \frac{1}{x} \right) \right| & \text{if } x \neq 0, \\
  0 & \text{if } x = 0.
\end{cases}$$

Then $f$ is locally Lipschitz around 0, Fréchet differentiable at 0 (and almost everywhere) but not strictly differentiable at 0, and there is no neighborhood $U$ of 0 such that $f$ is differentiable on $U$. Moreover, $f$ is semiregular (not strongly), strongly subregular at 0, and sur $f(0) = \liminf_{x \to 0} \text{lopen } f(x) = 0$, while $f'(0) = \text{lopen } f(0) = \text{popen } f(0) = 1$. In particular, the first inequality in Proposition 2.2 (i) is strict.

**Example 2.4.** Consider a function $f : \mathbb{R} \to \mathbb{R}$ given by

$$f(x) := \begin{cases} 
  x, & \text{if } x \leq 0, \\
  x - \frac{1}{n}, & \text{if } \frac{1}{n} < x \leq \frac{1}{n-1}, \quad n = 3, 4, \ldots, \\
  x - \frac{1}{2}, & \text{if } x > \frac{1}{2},
\end{cases}$$

and its epigraphical mapping $F(x) := \{ y \in \mathbb{R} : y \geq f(x) \}$, $x \in \mathbb{R}$. It is easy to check that lopen $F(x, y) = \infty$ if $y > f(x)$ and lopen $F(x, y) = 1$ if $y = f(x)$. Hence,

$$\liminf_{r \searrow 0} \{ \text{lopen } F(x, y) : (x, y) \in \text{gph } F \cap (\mathcal{B}(0, r) \times \mathcal{B}(0, r)) \} = 1.$$
Take any \( r > 0 \) and \( \varepsilon > 0 \), and choose an index \( n \in \mathbb{N} \) such that \( x_n := \frac{1}{n} + \frac{1}{n^2} < r \) and \( t_n := \frac{1}{n} < \varepsilon \). Then \( y_n := f(x_n) = \frac{1}{n^2} < r \) and
\[
\inf \{ c > 0 : \mathcal{B}[y_n, ct_n] \subset F(\mathcal{B}[x_n, t_n]) \} = \frac{1}{n}.
\]
Hence,
\[
\inf_{(x, y) \in gph F \cap (\mathcal{B}(0, r) \times \mathcal{B}(0, r))} \inf_{t \in (0, \varepsilon)} \sup \{ c > 0 : \mathcal{B}[y, ct] \subset F(\mathcal{B}[x, t]) \} = 0,
\]
and therefore \( \text{sur} F(0, 0) = 0 \). Consequently, the second inequality in Proposition \( \ref{prop:convexity} \) (i) is strict.

### 3 Primal and dual infinitesimal conditions

It is easy to check that \( \text{lopen} F(\bar{x}, \bar{y}) \) equals to
\[
\liminf_{y \to \bar{y}, y \not\in F(\bar{x})} \frac{\rho(y, \bar{y})}{\text{dist} (\bar{x}, F^{-1}(y))},
\]
with the convention that the limit in \( \ref{eq:1} \) is \( \infty \) when \( \bar{y} \) is an internal point in \( F(\bar{x}) \).

**Theorem 3.1.** Let \((X, d)\) be a metric space, \((Y, \rho)\) a complete metric space, and let \( F : X \rightrightarrows Y \) be a set-valued mapping such that \((\bar{x}, \bar{y}) \in gph F\) and the function \( y \mapsto \text{dist} (\bar{x}, F^{-1}(y)) \) is upper semicontinuous near \( \bar{y} \). Set
\[
\varphi(y) := \begin{cases} \frac{\rho(y, \bar{y})}{\text{dist} (\bar{x}, F^{-1}(y))}, & \text{if } y \neq \bar{y}, \\ 0, & \text{otherwise}, \end{cases}
\]
\[
|\nabla F|_{\text{SeR}}^\circ (\bar{x}, \bar{y}) := \liminf_{y \to \bar{y}, y \not\in F(\bar{x})} \frac{\rho(y, \bar{y})}{|\varphi(y) - \varphi(v)|} \sup_{v \neq y} \frac{\varphi(y) - \varphi(v)}{\rho(y, v)}.
\]
Then
\[
\frac{1}{2} |\nabla F|_{\text{SeR}}^\circ (\bar{x}, \bar{y}) \leq \text{lopen} F(\bar{x}, \bar{y}) \leq |\nabla F|_{\text{SeR}}^\circ (\bar{x}, \bar{y}).
\]
In particular, if numbers \( c > 0 \) and \( r > 0 \) are such that, for any \( y \in \mathcal{B}[\bar{y}, r] \setminus F(\bar{x}) \), there is a vector \( v \in Y \) satisfying
\[
\rho(y, \bar{y}) (\varphi(y) - \varphi(v)) > c \rho(y, v),
\]
then \( \text{lopen} F(\bar{x}, \bar{y}) \geq c/2 \).

**Proof.** Clearly,
\[
\text{lopen} F(\bar{x}, \bar{y}) = \liminf_{y \to \bar{y}, y \not\in F(\bar{x})} \varphi(y).
\]
We prove the first inequality in \( \ref{eq:2} \). If \( \text{lopen} F(\bar{x}, \bar{y}) = \infty \), the inequality holds trivially. Let \( \text{lopen} F(\bar{x}, \bar{y}) < \gamma < \infty \). We are going to show that \( |\nabla F|_{\text{SeR}}^\circ (\bar{x}, \bar{y}) \leq 2\gamma \). Note that \( \varphi \) is lower.
semicontinuous near \( \hat{y} \) and \( \varphi(y) \geq 0 \) for all \( y \in Y \). Choose a number \( \delta > 0 \) such that \( \varphi \) is lower semicontinuous on \( B[\hat{y}, 3\delta] \). By (25), there exists a point \( y' \in B[\hat{y}, \delta] \) such that \( y' \notin F(\bar{x}) \) and \( \varphi(y') < \gamma \). Set \( \delta' := \varphi(y', \hat{y}) \). Then \( 0 < \delta' \leq \delta \). Employing the Ekeland variational principle, we find a point \( \hat{y} \in B(y', \delta') \) such that \( \varphi(\hat{y}) \leq \varphi(y') \) and

(27) \[ \varphi(\hat{y}) \leq \varphi(v) + \frac{\gamma}{\delta'} \varphi(\hat{y}, v) \]

for all \( v \in B[\hat{y}, 3\delta] \). Since \( \varphi(\hat{y}) \leq \varphi(y') < \infty \), in view of (23), we have either \( \hat{y} \notin F(\bar{x}) \) or \( \hat{y} = \bar{y} \). At the same time,

\[ \varphi(\hat{y}, \bar{y}) \geq \varphi(y', \bar{y}) - \varphi(\hat{y}, y') > 0. \]

Thus, \( \hat{y} \neq \bar{y} \), and consequently, \( \hat{y} \notin F(\bar{x}) \).

If \( v \notin B[\bar{y}, 3\delta] \), then

\[ \varphi(\hat{y}) \leq \varphi(y') < \gamma \leq \frac{\gamma}{\delta'} \bar{y}(3\delta - 2\delta') < \frac{\gamma}{\delta'} (\varphi(v, \bar{y}) - \varphi(\hat{y}, \bar{y})) \leq \frac{\gamma}{\delta'} \varphi(\hat{y}, v) \leq \varphi(v) + \frac{\gamma}{\delta'} \varphi(\hat{y}, v). \]

Hence, inequality (27) holds true for all \( v \in Y \), and consequently,

\[ \varphi(\hat{y}, \bar{y}) \sup_{v \neq \hat{y}} \frac{\varphi(\hat{y}) - \varphi(v)}{\varphi(\hat{y}, v)} < 2\delta' \frac{\gamma}{\delta'} = 2\gamma. \]

Thus,

\[ \inf_{y \in B(\bar{y}, 3\delta) \setminus F(\bar{x})} \varphi(\hat{y}, \bar{y}) \sup_{v \neq \bar{y}} \frac{\varphi(y) - \varphi(v)}{\varphi(y, v)} < 2\gamma. \]

Passing to the limit as \( \delta \downarrow 0 \), we obtain \( |\nabla F|_{\text{ser}}(\bar{x}, \bar{y}) \leq 2\gamma \). Since \( \gamma > \text{open} \) \( F(\bar{x}, \bar{y}) \) is arbitrary, the first inequality in (25) is proved. Given any \( y \neq \bar{y} \), we have

\[ \varphi(y, \bar{y}) \sup_{v \neq \bar{y}} \frac{\varphi(y) - \varphi(v)}{\varphi(y, v)} \geq \varphi(y, \bar{y}) \frac{\varphi(y) - \varphi(\bar{y})}{\varphi(y, \bar{y})} = \varphi(y). \]

In view of the representations (24) and (26), this proves the second inequality in (25). \( \square \)

**Remark 3.2.** The second inequality in (25) is valid without the assumptions of the completeness of \( Y \) and upper semicontinuity of the function \( y \mapsto \text{dist}(\bar{x}, F^{-1}(y)) \). The last property holds, for example, if \( F^{-1} \) is lower semicontinuous, that is, when \( F \) is open at the corresponding reference point.

Let \( X \) and \( Y \) be normed spaces. Given a set \( \Omega \subset X \) and a point \( \bar{x} \in \Omega \), the *Fréchet normal cone* to \( \Omega \) at \( \bar{x} \), denoted by \( \hat{N}_\Omega(\bar{x}) \), is the set of all \( x^* \in X^* \) such that for every \( \varepsilon > 0 \) there exists \( \delta > 0 \) such that

\[ \langle x^*, x - \bar{x} \rangle \leq \varepsilon \|x - \bar{x}\| \quad \text{whenever} \quad x \in \Omega \cap B(\bar{x}, \delta). \]

For a mapping \( F : X \rightrightarrows Y \) with \( (\bar{x}, \bar{y}) \in \text{gph} F \), the *Fréchet coderivative* of \( F \) at \( (\bar{x}, \bar{y}) \) acts from \( Y^* \) to the subsets of \( X^* \) and is defined as

\[ Y^* \ni y^* \mapsto \hat{D}^*F(\bar{x}, \bar{y})(y^*) := \left\{ x^* \in X^* : \langle x^*, -y^* \rangle \in \hat{N}_{\text{gph} F}(\bar{x}, \bar{y}) \right\}. \]

We have the following dual necessary condition for semiregularity [30, Theorem 6 (iv)].
Theorem 3.3. Consider a mapping $F : X \Rightarrow Y$ between normed spaces $X$ and $Y$ and a point $(\bar{x}, \bar{y}) \in \text{gph } F$. Then

$$\text{lopen } F(\bar{x}, \bar{y}) \leq \inf_{y^* \in \partial_y} \{ \| x^* \| : x^* \in \hat{D}^* F(\bar{x}, \bar{y})(y^*) \}.$$ 

Hence, if $F$ is semiregular at $(\bar{x}, \bar{y})$ then

$$\hat{D}^* F^{-1}(\bar{y}, \bar{x})(0) = \{0\}.$$

In finite dimensions, using Brouwer’s fixed point theorem, we get:

Theorem 3.4. Consider a point $\bar{x} \in \mathbb{R}^n$ along with a mapping $f : \mathbb{R}^n \rightarrow \mathbb{R}^m$ which is both defined and continuous in a vicinity of $\bar{x}$. Suppose that there is a surjective linear mapping $A : \mathbb{R}^n \rightarrow \mathbb{R}^m$ such that $\text{calm}(f - A)(\bar{x}) < \text{sur } A$. Then $n \geq m$ and

$$\text{lopen } f(\bar{x}) \geq \text{sur } A - \text{calm}(f - A)(\bar{x}) > 0.$$ 

Proof. Clearly, if $n < m$, there is no chance to have a linear surjection from $\mathbb{R}^n$ onto $\mathbb{R}^m$. Therefore $n \geq m$. Without any loss of generality assume that $\bar{x} = 0$ and $f(\bar{x}) = 0$. Let us identify a linear mapping $A$ with its matrix representation in the canonical bases of $\mathbb{R}^n$ and $\mathbb{R}^m$. Then $A \in \mathbb{R}^{m \times n}$ has a full rank $m$. Hence the (symmetric) matrix $AA^T \in \mathbb{R}^{m \times m}$ is non-singular. Let $B := A^T (AA^T)^{-1} \in \mathbb{R}^{n \times m}$. Note that sur $A$ is equal to the smallest singular value of $A$ and $\|B\|$ is equal to the largest singular value of $B$. As

$$B^T B = (A^T (AA^T)^{-1})^T A^T (AA^T)^{-1} = ((AA^T)^{-1})^T = (AA^T)^{-1} = (AA^T)^{-1},$$

the singular values of $A$ and $B$ are reciprocal. Therefore $\|B\| = 1/\text{sur } A$. Pick any $c \in (0, \text{sur } A - \text{calm}(f - A)(0))$. Let $\gamma > 0$ be such that $\text{calm}(f - A)(0) + c + \gamma < \text{sur } A$. By the assumptions, there is $\varepsilon > 0$ such that $f$ is continuous on $B(0, 2\varepsilon)$ and

$$\|f(x) - Ax\| \leq (\text{calm}(f - A)(0) + \gamma) \|x\| \quad \text{whenever } x \in B(0, 2\varepsilon).$$

Fix any $t \in (0, \varepsilon)$. Pick an arbitrary $y \in B[0, ct]$. Define the mapping $h_y : B_{\mathbb{R}^n} \rightarrow \mathbb{R}^m$ by

$$h_y(t) := \frac{1}{t} B (A(tu) - f(tu) + y), \quad u \in B_{\mathbb{R}^n}.$$ 

Note that, for every $u \in B[0, 2]$, we have $tu \in B(0, 2\varepsilon)$. In particular, $h_y$ is well defined and continuous on $B_{\mathbb{R}^n}$. Given $u \in B_{\mathbb{R}^n}$, inequality (28) with $x := tu$ implies that

$$\|h_y(u)\| \leq \frac{1}{t} \|B\| \|((A(tu) - f(tu)) + y)\| \leq \frac{\|B\|}{t} \|((\text{calm}(f - A)(0) + \gamma) \|tu\| + \|y\|) \leq \frac{\|B\|}{t} \|((\text{calm}(f - A)(0) + \gamma) t + ct)\| \leq \|B\| \|((\text{calm}(f - A)(0) + c + \gamma) < \|B\| \text{ sur } A = 1.$$ 

Therefore $h_y$ maps $B_{\mathbb{R}^n}$ into itself. Using Brouwer’s fixed point theorem, we find $u_y \in B_{\mathbb{R}^n}$ such that $h_y(u_y) = u_y$. Hence $Ah_y(u_y) = Au_y$. As $AB = I_{\mathbb{R}^m}$, the definition of $h_y$ implies that

$$A(tu_y) - f(tu_y) + y = tA(u_y) = A(u_y).$$

Then $x_y := tu_y$ is such that $f(x_y) = y$ and $\|x_y\| \leq t$. Hence $y \in f(B[0, t])$. Since $y \in B[0, ct]$ was chosen arbitrarily, we have $B[0, ct] \subset f(B[0, t])$. Therefore lopen $f(\bar{x}) \geq c$. Letting $c \uparrow (\text{sur } A - \text{calm}(f - A)(0))$, we finish the proof. $\square$
The above statement is quite similar to Theorem 3.4 with one important difference. If, in addition to the assumptions of Theorem 3.4, the mapping $A$ is invertible, then $n = m$ and $\text{sur } A = 1/\|A^{-1}\|$. Consequently,

$$\text{lopen } f(\bar{x}) \geq 1/\|A^{-1}\| - \text{calm}(f - A)(\bar{x}).$$

However, Example 2.3 shows that one cannot conclude that $f$ is strongly semiregular at $\bar{x}$, that is, that the mapping $f^{-1}$ has a single-valued localization around $(\bar{x}, f(\bar{x}))$. This example also shows that we can have $f(\bar{x}) = 0$ although all the assumptions of Theorem 3.4 hold.

We immediately obtain that the surjectivity of the Fréchet derivative at the reference point implies the openness with a linear rate of the mapping in question at this point. The following statement improves [13, Corollary 1G.6] where a weaker property of openness is shown. This statement was motivated by a discussion of the second author with V. Kaluža, who suggested a proof using Borsuk-Ulam theorem.

**Corollary 3.5.** Consider a point $\bar{x} \in \mathbb{R}^n$ along with a mapping $f : \mathbb{R}^n \to \mathbb{R}^m$ which is both defined and continuous in a vicinity of $\bar{x}$ and Fréchet differentiable at $\bar{x}$. If $f'(\bar{x})$ is surjective, then $n \geq m$ and $\text{lopen } f(\bar{x}) \geq \text{sur } f'(\bar{x}) > 0$.

We also obtain an extension of [13, Theorem 1G.3].

**Theorem 3.6.** Suppose that the assumptions of Theorem 3.4 hold and denote by $\Sigma$ the set of all selections for $f^{-1}$ defined in a vicinity of $\bar{y} := f(\bar{x})$. Then

$$\inf_{\sigma \in \Sigma} \text{calm } \sigma(\bar{y}) \leq \frac{1}{\text{sur } A - \text{calm}(f - A)(\bar{x})}$$

and

$$\inf_{\sigma \in \Sigma} \text{calm}(\sigma - AT(AAT)^{-1})(\bar{y}) \leq \frac{\text{calm}(f - A)(\bar{x})}{\text{sur } (A + \text{calm}(f - A)(\bar{x}))}.$$  

In particular, if $f$ is Fréchet differentiable at $\bar{x}$, then there is $\sigma \in \Sigma$ which is Fréchet differentiable at $\bar{y}$ and

$$\sigma'(\bar{y}) = [f'(\bar{x})]^*(f'(\bar{x}) [f'(\bar{x})]^*)^{-1}).$$

**Proof.** Let $B$, $c$, $\gamma$, $\varepsilon$, and $t$ be as in the proof of Theorem 3.4. Consider the mapping

$$V := \mathcal{B}[0, ct] \ni y \rightarrow \sigma(y) := x_y \in \mathcal{B}[0, t] =: U,$$

where $x_y$ is such that $h_y(x_y/t) = x_y/t$ with $h_y$ defined in (29). We already know that $f(\sigma(y)) = y$ for each $y \in V$. Moreover, given $y \in V$, we have by (29) and (28)

$$\|\sigma(y)\| = \|th_y(\sigma(y)/t)\| = \|B(A(\sigma(y)) - f(\sigma(y)) + y)\| \leq \|B\|((\text{calm}(f - A)(0) + \gamma)\|\sigma(y)\| + \|y\|).$$

As $\|B\| = 1/\text{sur } A$ and $\text{calm}(f - A)(0) + \gamma < \text{sur } A$, the above estimate implies that

$$\|\sigma(y)\| \leq \frac{1}{\text{sur } A - \text{calm}(f - A)(0) - \gamma}\|y\| \quad \text{whenever } y \in V.$$
Moreover, for a fixed $y \in V$, we have by (29) and (28)
\[
\| \sigma(y) - By \| = \| th_y(\sigma(y)/t) - By \| = \| B(A(\sigma(y)) - f(\sigma(y))) \|
\leq \| B \| (\text{calm}(f - A)(0) + \gamma \|y\|) \|\sigma(y)\|.
\]
Using (30), we get
\[
\| \sigma(y) - By \| \leq \frac{\text{calm}(f - A)(0) + \gamma}{\text{sur } A (\text{sur } A - \text{calm}(f - A)(0) - \gamma)} \|y\| \quad \text{whenever } y \in V.
\]
As $\gamma > 0$ can be arbitrarily small, (30) and (31), respectively, imply the desired estimates.

To prove the second part, it suffices to observe that if $f$ is Fréchet differentiable at $\bar{x}$ then calm$(f - f'(\bar{x}))(\bar{x}) = 0$.

A similar approach as in the proof of Theorem 3.4 but applying Kakutani’s fixed point theorem instead of Brouwer’s theorem, yields a sufficient condition for openness with a linear rate of a set-valued mapping satisfying certain “strong monotonicity/ellipticity” assumptions.

**Theorem 3.7.** Consider positive constants $\ell$ and $r$, a point $(\bar{x}, \bar{y}) \in \mathbb{R}^n \times \mathbb{R}^n$, and a mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ with $(\bar{x}, \bar{y}) \in \text{gph } F$. Assume that $F$ has a closed graph and convex values, the set $F(\mathbb{B}[\bar{x}, r])$ is bounded, and that one of the following conditions holds:

(C1) for each $x \in \mathbb{B}[\bar{x}, r]$ there is $y \in F(x)$ such that $\langle y - \bar{y}, x - \bar{x} \rangle \geq \ell \|x - \bar{x}\|^2$;

(C2) for each $x \in \mathbb{B}[\bar{x}, r]$ there is $y \in F(x)$ such that $\langle y - \bar{y}, x - \bar{x} \rangle \geq \ell \|x - \bar{x}\|^2$.

Then lopen $F(\bar{x}, \bar{y}) \geq \ell$; more precisely,
\[
\mathbb{B}[y, \ell t] \subset F(\mathbb{B}[\bar{x}, t]) \quad \text{for each } t \in (0, r].
\]

**Proof.** Note that (32) for $F$ satisfying (C2) follows by considering the reference point $(\bar{x}, -\bar{y})$ and the mapping $-F$, which necessarily satisfies (C1). Suppose that (C1) holds. Assume without any loss of generality that $(\bar{x}, \bar{y}) = (0, 0)$. Find $m > 0$ such that $F(\mathbb{B}[0, r]) \subset \mathbb{B}[0, m]$.

First, we show that
\[
\mathbb{B}[0, ct] \subset F(\mathbb{B}[0, t]) \quad \text{for each } c \in (0, \ell) \text{ and each } t \in (0, r].
\]
Let $c$ and $t$ be as in (33). Fix an arbitrary (non-zero) $y \in \mathbb{B}[0, ct]$. Pick $\alpha > 0$ such that
\[
2\alpha \ell < 1 \quad \text{and} \quad \alpha(m + cr)^2 < 2(\ell - c)t^2.
\]
Define the mapping $H : \mathbb{B}[0, t] \to \mathbb{B}[0, t]$, depending on the choice of $(y, c, t, \alpha)$, by
\[
H(u) := (u + \alpha(y - F(u))) \cap \mathbb{B}[0, t], \quad u \in \mathbb{B}[0, t].
\]
Fix any $u \in \mathbb{B}[0, t]$. Using (C1), we find a point $v \in F(u)$ such that $\langle v, u \rangle \geq \ell \|u\|^2$. Let $z := u + \alpha(y - v)$. Then
\[
\|z\|^2 = \|u\|^2 + 2\alpha \langle u, y - v \rangle + \alpha^2 \|y - v\|^2 = \|u\|^2 - 2\alpha \langle v, u \rangle + 2\alpha \langle u, y \rangle + \alpha^2 \|y - v\|^2
\leq (1 - 2\alpha \ell)\|u\|^2 + 2\alpha \|u\|\|y\| + \alpha^2 (\|v\| + \|y\|)^2
\leq (1 - 2\alpha \ell)t^2 + 2\alpha t(c) + \alpha^2 (m + cr)^2 < (1 + 2\alpha(c - \ell))t^2 + 2\alpha(\ell - c)t^2 = t^2.
\]
Hence $z \in H(u)$. Consequently, the domain of $H$ is equal to $I B[0, t]$, which is a non-empty compact convex set. Since $F$ has closed graph and convex values, we conclude that $H$ has the same properties. Applying Kakutani’s fixed point theorem, we find $u \in I B[0, t]$ such that $u \in H(u)$. This implies that $y \in F(u) \subset F(I B[0, t])$. As $y \in I B[0, ct]$, and also $(c, t) \in (0, \ell) \times (0, r]$ are arbitrary, (33) is proved.

To show (32), fix any $t \in (0, r]$. Pick an arbitrary $y \in I B[0, \ell t]$. Let $y_k := (1 - 1/k)y$ for each $k \in \mathbb{N}$. Then $(y_k)$ converges to $y$. For each $k \geq 2$, using (33) with $c := (1 - 1/k)\ell$, we find $x_k \in I B^n$ such that $y_k \in F(x_k)$ and $\|x_k\| \leq t$. Passing to a subsequence, if necessary, we may assume that $(x_k)$ converges to, say, $x \in I B^n$. Then $\|x\| \leq t$ and $y \in F(x)$ because $\text{gph} F$ is closed. So $F(I B[0, t])$ contains $y$, which is an arbitrary point in $I B[0, \ell t]$.

The above statement implies [5, Theorem 1 and Corollary 1] under slightly weaker assumptions and the above proof also shows that there is no need to extend the locally defined mapping under consideration on the whole space.

**Corollary 3.8.** Consider positive constants $\ell$ and $r$, a point $\bar{x} \in \mathbb{R}^n$, and a mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ with $\text{dom} F = I B[\bar{x}, r]$. Assume that $F$ is upper semicontinuous, has compact convex values, and

\[
\forall x \in I B[\bar{x}, r] \forall \bar{y} \in F(\bar{x}) \exists y \in F(x) : \langle \bar{y} - y, x - \bar{x} \rangle \geq \ell \|x - \bar{x}\|^2.
\]

Then, for each $y \in \mathbb{R}^n$ such that $\text{dist} (y, F(\bar{x})) \leq r\ell$, there is $x \in I B[\bar{x}, r]$ satisfying

$y \in F(x) \quad \text{and} \quad \|x - \bar{x}\| \leq \frac{1}{\ell} \text{dist} (y, F(\bar{x})).$

**Proof.** Since $F$ is upper semicontinuous and has compact values, using a standard compactness argument we conclude that the set $F(I B[\bar{x}, r])$ is bounded. Moreover, $\text{gph} F$ is closed since $F$ is upper semicontinuous with closed values, closed domain, and bounded range. Fix any $y \in \mathbb{R}^n$ with $r\ell \geq \text{dist} (y, F(\bar{x}))$ ($> 0$). As $F(\bar{x})$ is a compact set, there is $\bar{y} \in \mathbb{R}^n$ such that $\|y - \bar{y}\| = \text{dist} (y, F(\bar{x}))$. Now (34) implies that (C2) is satisfied. By (32) with $t := \|y - \bar{y}\|/\ell \leq r$, there is $x \in I B[\bar{x}, \|y - \bar{y}\|/\ell] = I B[\bar{x}, \text{dist} (y, F(\bar{x}))/\ell] \subset I B[\bar{x}, r]$ such that $y \in F(x)$.

We also get:

**Corollary 3.9.** Consider positive constants $\ell$ and $r$, a point $\bar{x} \in \mathbb{R}^n$, and a mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ with $\text{dom} F = I B[\bar{x}, 2r]$. Assume that $F$ is upper semicontinuous, has compact convex values, and

\[
\forall x, x' \in I B[\bar{x}, 2r] \forall y \in F(x) \exists y' \in F(x') : \langle y - y', x' - x \rangle \geq \ell \|x' - x\|^2.
\]

Then $\text{sur} F(\bar{x}, \bar{y}) \geq \ell$; more precisely,

\[
I B[y, \ell t] \subset F(I B[\bar{x}, t]) \quad \text{whenever} \quad (x, y) \in (I B[\bar{x}, r] \times I B[\bar{y}, r]) \cap \text{gph} F \quad \text{and} \quad t \in (0, r].
\]

**Proof.** Fix any $(x, y)$ and $t$ as in (36). Then $I B[x, r] \subset I B[\bar{x}, 2r]$. Hence, (33) implies that for each $x' \in I B[x, r]$ there is $y' \in F(x')$ such that $\langle y - y', x' - x \rangle \geq \ell \|x' - x\|^2$, which is (C2) with $(\bar{x}, \bar{y}, x, y)$ replaced by $(x, y, x', y')$. As in the proof of Corollary 3.8, we conclude that all the assumptions of Theorem 3.7 with $(\bar{x}, \bar{y}) := (x, y)$ are satisfied.

16
Remark 3.10. Given \( \ell > 0 \), condition (34) holds, in particular, if \( F \) is relaxed one-sided Lipschitz (ROSL) on \( \mathcal{B}[\bar{x}, r] \) with the constant \( -\ell \) in the sense of [5, Definition 1], that is,

\[ \forall x, x' \in \mathcal{B}[\bar{x}, r] \quad \forall y \in F(x) \quad \exists y' \in F(x') : \langle y - y', x - x' \rangle \leq -\ell \|x - x'\|^2. \]

Condition (35) means that \( F \) is ROSL on \( \mathcal{B}[\bar{x}, 2r] \) with the constant \( -\ell \). Up to minor changes in notation, Corollary 3.9 seems to be the statement which the authors tried to formulate and prove in [5, Corollary 2 (ii)] under an additional assumption that \( F \) is (Hausdorff) continuous. However, their formulation seems to be not completely correct, since (local) metric regularity at \((\bar{x}, \bar{y})\) presumes the reference point to lie in \( \text{gph } F \). So the assumption in [5, Corollary 2 (ii)] that \( \text{dist} (\bar{y}, F(\bar{x})) \) is small enough holds trivially. Also note that “a slightly generalized definition of metric regularity” in [5] is nothing else but the usual definition of this property because \( F : \mathbb{R}^n \rightrightarrows \mathbb{R}^n \) in [13] means neither that \( \text{dom } F = \mathbb{R}^n \) nor that \( \bar{x} \) is an interior point of \( \text{dom } F \).

Remark 3.11. A sufficient condition for semiregularity of a continuous (possibly nonsmooth) mapping \( f : \mathbb{R}^n \to \mathbb{R}^n \) by using equi-invertibility of a pseudo-Jacobian can be found in [22, Theorem 3.2.1].

4 General conditions and semiregularity of the sum

First, we present sufficient as well as necessary conditions for semiregularity of a single-valued mapping.

**Proposition 4.1.** Let \( (X, d) \) be a complete metric space and \( (Y, \rho) \) be a metric space. Consider a point \( \bar{x} \in X \), a continuous mapping \( g : X \to Y \), whose domain is all of \( X \), and positive constants \( c \) and \( r \).

(i) Assume that for every \( x \in \mathcal{B}(\bar{x}, r) \) and every \( y \in \mathcal{B}(g(\bar{x}), cr) \) satisfying

\[ 0 < \rho(g(x), y) \leq \rho(g(\bar{x}), y) - c d(x, \bar{x}) \]

there is a point \( x' \in X \) such that

\[ \rho(g(x'), y) < \rho(g(x), y) - c d(x, x'). \]

Then \( g(\mathcal{B}(\bar{x}, t)) \supset \mathcal{B}(g(\bar{x}), ct) \) for every \( t \in (0, r) \).

(ii) Assume that \( g(\mathcal{B}(\bar{x}, t)) \supset \mathcal{B}(g(\bar{x}), ct) \) for every \( t \in (0, r) \). Then for every \( c' \in (0, c) \), every \( x \in \mathcal{B}(\bar{x}, r) \), and every \( y \in \mathcal{B}(g(\bar{x}), c'r) \) satisfying

\[ 0 < \rho(g(\bar{x}), y) \leq \rho(g(x), y) - c' d(x, \bar{x}) \]

there is a point \( x' \in X \) such that

\[ \rho(g(x'), y) < \rho(g(x), y) - c' d(x, x'). \]
Assume, on the contrary, that \( g \) is arbitrary, the proof is finished.

Then (39) implies that (37) with Proposition 4.2.

Employing the Ekeland variational principle, we find a point \( u \in X \) such that

\[
\varrho(g(u), y) \leq \varrho(g(\bar{x}), y) - c d(u, \bar{x})
\]

and

\[
\varrho(g(v), y) \geq \varrho(g(u), y) - c d(v, u) \quad \text{for every } v \in X.
\]

By (39), we have that \( c d(u, \bar{x}) \leq \varrho(g(\bar{x}), y) < ct \). Hence \( u \in B(\bar{x}, t) \). We claim that \( g(u) = y \).

Assume, on the contrary, that \( g(u) \neq y \). As \( t < r \), we have \( u \in B(\bar{x}, r) \) and \( y \in B(g(\bar{x}), cr) \). Then (39) implies that (37) with \( x := u \) holds. Find a point \( x' \in X \) such that \( \varrho(g(x'), y) < \varrho(g(u), y) - c d(u, x') \). Setting \( v := x' \) in (40), we get that \( \varrho(g(x'), y) \geq \varrho(g(u), y) - c d(u, x') \), a contradiction. Consequently \( y = g(u) \) as claimed, and so \( y \in B(g(\bar{x}, ct)) \). Since \( y \in B(g(\bar{x}), ct) \) is arbitrary, the proof is finished.

(ii) Fix any \( c' \in (0, c) \), any \( x \in B(\bar{x}, r) \), and any \( y \in B(g(\bar{x}), c'r) \) satisfying (38). Let \( t := \varrho(g(\bar{x}), y) / c' \). The choice of \( y \) implies that \( 0 < t < (c'r)/c' = r \). As \( y \in B[g(\bar{x}), ct] \subset B(g(\bar{x}), ct) \) there is \( x' \in B(\bar{x}, t) \) such that \( g(x') = y \). Then

\[
c' d(x, x') < c' d(x, \bar{x}) + c't \leq \varrho(g(x), y) - \varrho(g(\bar{x}), y) + c't = \varrho(g(x), y) = \varrho(g(x), y) - \varrho(g(x'), y).
\]

Although the above statement concerns single-valued mappings, using the restriction of the canonical projection to the graph of a given set-valued mapping we immediately get its set-valued version. Moreover, it can be directly used to establish semiregularity of the sum of two set-valued mappings - Theorem 4.4 below.

**Proposition 4.2.** Let \((X, d)\) and \((Y, g)\) be metric spaces and a point \((\bar{x}, \bar{y}) \in X \times Y\) be given. Consider a set-valued mapping \(F : X \rightrightarrows Y\), with \(\bar{y} \in F(\bar{x})\), for which there are positive constants \(c, r, \) and \(\alpha\) such that \(ac < 1\) and that the set \(gph F \cap (B[\bar{x}, r] \times B[\bar{y}, r/\alpha])\) is complete.

(i) Assume that for every \(x \in B(\bar{x}, r)\), every \(v \in B(\bar{y}, r/\alpha) \cap F(x)\), and every \(y \in B(\bar{y}, cr)\) satisfying

\[
0 < \varrho(v, y) \leq \varrho(\bar{y}, y) - c \max\{d(x, \bar{x}), \alpha g(v, \bar{y})\}
\]

there is a pair \((x', v') \in gph F\) such that

\[
\varrho(v', y) < \varrho(v, y) - c \max\{d(x, x'), \alpha g(v, v')\}.
\]

Then \(F(B(\bar{x}, t)) \supset B(\bar{y}, ct)\) for every \(t \in (0, r)\).

(ii) Assume that \(F(B(\bar{x}, t)) \supset B(\bar{y}, ct)\) for every \(t \in (0, r)\). Then for every \(c' \in (0, c)\), every \(x \in B(\bar{x}, r)\), every \(v \in B(\bar{y}, r/\alpha) \cap F(x)\), and every \(y \in B(\bar{y}, c'r)\) satisfying

\[
0 < \varrho(\bar{y}, y) \leq \varrho(v, y) - c' \max\{d(x, \bar{x}), \alpha g(v, \bar{y})\}
\]

there is a pair \((x', v') \in gph F\) such that

\[
\varrho(v', y) < \varrho(v, y) - c' \max\{d(x, x'), \alpha g(v, v')\}.
\]
Proof. (i) Define the (compatible) metric $\bar{d}$ on the space $X \times Y$ for each $(u, w), (u', w') \in X \times Y$ by $\bar{d}((u, w), (u', w')) := \max\{d(u, u'), \alpha g(w, w')\}$. Then $\tilde{X} := (\mathcal{B}[\bar{x}, r] \times \mathcal{B}[\bar{y}, r/\alpha]) \cap \text{gph } F$, equipped with $\bar{d}$, is a complete metric space. Let $g : \tilde{X} \to Y$ be defined by $g(x, y) = y$, $(x, y) \in \tilde{X}$. Then $g$ is a continuous mapping defined on the whole $\tilde{X}$. Fix any $(x, v) \in \mathcal{B}_\tilde{X}((\bar{x}, \bar{y}), r) = (\mathcal{B}(\bar{x}, r) \times \mathcal{B}(\bar{y}, r/\alpha)) \cap \text{gph } F \subset \tilde{X}$ and any $y \in \mathcal{B}(\bar{y}, c r)$ such that (41) holds. Find a pair $(x', v') \in \text{gph } F$ satisfying (42). Then

$$
\bar{d}((x', v'), (\bar{x}, \bar{y})) \leq \bar{d}((x', v'), (x, v)) + \bar{d}((\bar{x}, \bar{y}), (x, v)) \leq \frac{\rho(v, y) - \rho(v', y)}{c} + \frac{\rho(\bar{y}, y) - \rho(v, y)}{c} = \frac{\rho(\bar{y}, y) - \rho(v', y)}{c} \leq \frac{cr}{c} = r.
$$

Hence, $(x', v') \in \tilde{X}$. Proposition 4.1 with $(X, d, (\bar{x}, \bar{y})) := (\tilde{X}, \bar{d}, (\bar{x}, \bar{y}))$, implies that

$$
\mathcal{B}(\bar{y}, ct) \subset g\left((\mathcal{B}(\bar{x}, t) \times \mathcal{B}(\bar{y}, t/\alpha)) \cap \text{gph } F\right)
$$

for each $t \in (0, r)$.

Fix an arbitrary $t \in (0, r)$. Given $y \in \mathcal{B}(\bar{y}, ct)$, there are $x \in \mathcal{B}(\bar{x}, t)$ and $y' \in \mathcal{B}(\bar{y}, t/\alpha) \cap F(x)$ such that $g(x, y') = y$, hence $y' = y$ and consequently $y \in F(x)$. Thus $\mathcal{B}(\bar{y}, ct) \subset F(\mathcal{B}(\bar{x}, t))$.

(ii) Fix any $c' \in (0, c)$, then fix any $(x, v) \in \text{gph } F \cap (\mathcal{B}(\bar{x}, r) \times \mathcal{B}(\bar{y}, r/\alpha))$ and any $y \in \mathcal{B}(\bar{y}, c'r)$ satisfying (43). Let $t := g(\bar{y}, y)/c'$. The choice of $y$ implies that $0 < t < c'r/c' = r$. As $y \in \mathcal{B}(\bar{y}, c't) \subset \mathcal{B}(\bar{y}, ct)$ there is $x' \in \mathcal{B}(\bar{x}, t)$ such that $F(x') \ni y$. Let $v' := y$. Then

$$
c'd(x, x') \overset{(\Delta)}{=} c'd(x, \bar{x}) + c't \leq \rho(v, y) - \rho(\bar{y}, y) + c't = \rho(v, y) = \rho(v, y) - \rho(v', y)
$$

and

$$
c'\alpha g(v, v') < \rho(v, v') = \rho(v, y) - \rho(v', y).
$$

The next example shows that the assumptions of Proposition 4.2(i) do not imply that the mapping under consideration is regular around the reference point and can provide a tight lower estimate for the corresponding modulus.

Example 4.3. Let $(X, d) := (Y, g) := (\mathbb{R}, | \cdot |)$ and $(\bar{x}, \bar{y}) := (0, 0)$. Consider a set-valued mapping $\mathbb{R} \ni x \mapsto F(x) := \{x, 0\} \subset \mathbb{R}$. Then $F$ has a closed graph and sur $F(0, 0) = 0$ while open $F(0, 0) = 1$. Fix any $c \in (0, 1)$, any $\alpha \in (0, 1/c)$, and any $r > 0$. Pick any $x \in \mathcal{B}(0, r)$, any $v \in \mathcal{B}(0, r/\alpha) \cap F(x)$, and any $y \in \mathcal{B}(0, cr)$ satisfying

$$
0 < |v - y| \leq |y| - c \max\{|x|, \alpha|v|\}.
$$

Let $(x', v') := (y, y) \in \text{gph } F$. If $v \neq 0$ then $v = x$ and consequently $x \neq y$ by (43). Hence $c|x - x'| < |x - x'| = |v - y| = |v - y| - |v' - y|$ and $\alpha c|v - v'| < |v - v'| = |v - y| = |v - y| - |v' - y|$. If $v = 0$ then (41) implies that $y \neq 0$ and $x = 0$. Thus $c|x - x'| = c|x| < |x'| = |y| = |y| - |v' - y|$ and $\alpha c|v - v'| = \alpha c|v'| < |v'| = |y| = |y| - |v' - y|$. In both the cases, we showed that

$$
c \max\{|x - x'|, \alpha|v - v'|\} < |v - y| - |v' - y|.
$$

Proposition 4.2 implies that open $F(0, 0) \geq c$ for any $c \in (0, 1)$. 19
Theorem 4.4. Let \((X, d)\) be a complete metric space, \((Y, g)\) be a complete linear metric space with a shift-invariant metric, and a point \((\bar{x}, \bar{y}, \bar{z}) \in X \times Y \times Y\) be given. Consider set-valued mappings \(F, G : X \to Y\), with \((\bar{y}, \bar{z}) \in F(\bar{x}) \times G(\bar{x})\), for which there are positive constants \(c', r\), and \(\ell < c'\) such that both the sets \(\text{gph} \cap (\mathcal{B}[\bar{x}, 2r] \times \mathcal{B}[\bar{y}, 2c'r])\) and \(\text{gph} \cap (\mathcal{B}[\bar{x}, 2r] \times \mathcal{B}[\bar{z}, 2\ell r])\) are closed; that

\[
\forall \quad \mathcal{B}(v, c') \subset F(\mathcal{B}(x, \tau)) \quad \text{whenever} \quad x \in \mathcal{B}(\bar{x}, r), \quad v \in F(x) \cap \mathcal{B}(\bar{y}, c' r), \quad \text{and} \quad \tau \in (0, r);
\]

and that

\[
\forall \quad G(x) \cap \mathcal{B}(\bar{z}, \ell r) \subset G(x') + \ell d(x, x') \mathcal{B}_Y \quad \text{for each} \quad x, x' \in \mathcal{B}(\bar{x}, 2r).
\]

Then

\[
(F + G)(\mathcal{B}(\bar{x}, t)) \supset \mathcal{B}(\bar{y} + \bar{z}, (c - \ell) t) \quad \text{whenever} \quad c \in (\ell, c') \quad \text{and} \quad t \in (0, r).
\]

Proof. Fix any \(c \in (\ell, c')\). Define the (compatible) metric on \(X \times Y \times Y\) by

\[
\bar{d}((x, v, z), (x', v', z')) := \max\{d(x, x'), g(v, v')/c', g(z, z')/\ell\}, \quad (x, v, z), (x', v', z') \in X \times Y \times Y.
\]

Let

\[
\bar{X} := \{(x, v, z) \in X \times Y \times Y : x \in \mathcal{B}[\bar{x}, 2r], v \in F(x) \cap \mathcal{B}[\bar{y}, 2c'r], z \in G(x) \cap \mathcal{B}[\bar{z}, 2\ell r]\}.
\]

Then \(\bar{X}\) is a (nonempty) closed subset of \(X \times Y \times Y\), hence \((\bar{X}, \bar{d})\) is a complete metric space. Let \(g : \bar{X} \to Y\) be defined by

\[
g(x, v, z) := v + z, \quad (x, v, z) \in \bar{X}.
\]

Then \(g\) is a continuous mapping defined on the whole \(\bar{X}\). Fix any \((x, v, z) \in \mathcal{B}_X((\bar{x}, \bar{y}, \bar{z}), r) \subset \mathcal{B}(\bar{x}, r) \times \mathcal{B}(\bar{y}, c'r) \times \mathcal{B}(\bar{z}, \ell r)\) and any \(y \in \mathcal{B}(\bar{y} + \bar{z}, (c - \ell)r)\) such that

\[
0 < g(x, v, z) \leq g(\bar{y} + \bar{z}, y) - (c - \ell)\bar{d}((x, v, z), (\bar{x}, \bar{y}, \bar{z})).
\]

Let \(\tau := g(x, v, z)/c\). Then \(0 < \tau \leq g(\bar{y} + \bar{z}, y)/c < (c - \ell)r/c < r\). As

\[
g(y - z, v) = g(y - z, g(x, v, z) - z) = g(y, g(x, v, z)) = c\tau < c'\tau,
\]

we have \(v' := y - z \in \mathcal{B}_Y(v, c'\tau)\). By \((45)\), there is \(x' \in \mathcal{B}(x, \tau)\) such that \(v' \in F(x')\). Then

\[
d(x', \bar{x}) \leq d(x', x) + d(x, \bar{x}) < \tau + r < 2r.
\]

Since \(z \in G(x) \cap \mathcal{B}(\bar{z}, \ell r)\), using \((16)\), we find \(z' \in G(x')\) such that \(g(z, z') \leq \ell d(x, x') < \ell \tau\). Then

\[
g(z', \bar{z}) \leq g(z', z) + g(z, \bar{z}) < \ell \tau + \ell r < 2\ell r \quad \text{and} \quad g(v', \bar{y}) \leq g(v', v) + g(v, \bar{y}) < c\tau + c'r < 2c'r,
\]

hence, remembering \((48)\), we conclude that \((x', v', z') \in \bar{X}\). Moreover,

\[
g(g(x', v', z'), y) = g(y - z + z', y) = g(z', z) < \ell \tau = c\tau - (c - \ell)\tau = g(g(x, v, z), y) - (c - \ell)\tau.
\]
Since \(d(x', x) < \tau\), \(g(v', v) < c'\tau\), and \(g(z', z) < \ell\tau\), we get that
\[
g(\ellopen(F, z', y)) < g(g(x, v, z), y) - (c - \ell)d((x, v, z), (x', v', z')).
\]

Proposition 4.4 with \((\widetilde{X}, \widetilde{d}, (\bar{x}, \bar{y}, \bar{z}), c - \ell)\) instead of \((X, d, \bar{x}, c)\), implies that
\[
g(\mathcal{B}(\bar{x}, \bar{y}, \bar{z}), t) \supseteq \mathcal{B}(\bar{y} + \bar{z}, (c - \ell)t)
\]
for each \(t \in (0, r)\).

Consequently, given \(t \in (0, r)\) and \(y \in \mathcal{B}(\bar{y} + \bar{z}, (c - \ell)t)\), there are \(x \in \mathcal{B}(\bar{x}, t)\), \(v \in F(x) \cap \mathcal{B}(\bar{y}, c't)\), and \(z \in G(x) \cap \mathcal{B}(\bar{z}, \ell t)\) such that \(y = v + z\), that is, \(y \in F(x) + G(x) \subseteq (F + G)(\mathcal{B}(\bar{x}, t))\).

Using the above statement we immediately get the following result:

**Theorem 4.5.** Let \((X, d)\) be a complete metric space, \((Y, g)\) be a complete linear metric space with a shift-invariant metric, and a point \((\bar{x}, \bar{y}, \bar{z}) \in X \times Y \times Y\) be given. Consider set-valued mappings \(F, G : X \Rightarrow Y\) such that \(F\) has a locally closed graph around \((\bar{x}, \bar{y}) \in \text{gph} F\) and \(G\) has a locally closed graph around \((\bar{x}, \bar{z}) \in \text{gph} G\). Then
\[
\text{lopopen}(F + G)(\bar{x}, \bar{y} + \bar{z}) \geq \text{sur}(F(\bar{x}, \bar{y}) - \text{lip} G(\bar{x}, \bar{z})).
\]

**Proof.** If \(\text{sur} F(\bar{x}, \bar{y}) \leq \text{lip} (\bar{x}, \bar{z})\) we are done. Suppose that \(\text{sur} F(\bar{x}, \bar{y}) > \text{lip} G(\bar{x}, \bar{z})\). Fix any \(c, c', \ell\) such that \(\text{lip} G(\bar{x}, \bar{z}) < \ell < c < c' < \text{sur} F(\bar{x}, \bar{y})\). Using the definitions, we find a small enough \(r > 0\) such that all the assumptions of Theorem 4.4 are satisfied. By (47), we get \(\text{lopopen}(F + G)(\bar{x}, \bar{y} + \bar{z}) \geq c - \ell\). Letting \(\ell \downarrow \text{lip} G(\bar{x}, \bar{z})\) and \(c \uparrow \text{sur} F(\bar{x}, \bar{y})\), we get (49). \(\Box\)

**Remark 4.6.**

1. It is well known, that one cannot replace \(\text{lopopen}(F + G)(\bar{x}, \bar{y} + \bar{z})\) by \(\text{sur}(F + G)(\bar{x}, \bar{y} + \bar{z})\) in (49), as the following elementary example shows (see also [13] Example 5.1 for a more elaborate one). Let \((X, d) := (Y, g) := (\mathbb{R}, | \cdot |)\) and \((\bar{x}, \bar{y}, \bar{z}) := (0, 0, 0)\). Consider set-valued mappings \(\mathbb{R} \ni x \mapsto F(x) := \{x, -1\} \subseteq \mathbb{R}\) and \(\mathbb{R} \ni x \mapsto G(x) := \{1\} \subseteq \mathbb{R}\). Then \(F\) and \(G\) have closed graphs, \(\text{sur} F(0, 0) = 1\), and \(\text{lip} G(0, 0) = 0\). Then \((F + G)(x) = \{x, -1, x + 1, 0\}\) for each \(x \in \mathbb{R}\). Consequently, \(\text{lopopen}(F + G)(0, 0) = 1\) while \(\text{sur} (F + G)(0, 0) = 0\).

2. Suppose that the assumptions of Theorem 4.4 hold and let \((\bar{x}, \bar{y}, \bar{z}) \in \mathcal{B}(\bar{x}, r/2) \times \mathcal{B}(\bar{y}, c'r/2) \times \mathcal{B}(\bar{z}, \ell r/2)\) with \((\bar{y}, \bar{z}) \in F(\bar{x}) \times G(\bar{x})\) be arbitrary. Defining \(\widetilde{X}, \widetilde{d}, \text{and } g\) as in the proof of Theorem 4.4 and replacing \((\bar{x}, \bar{y}, \bar{z}, r)\) by \((\bar{x}, \bar{y}, \bar{z}, r/2)\) in the rest of the proof, we get that
\[
(F + G)(\mathcal{B}(\bar{x}, t)) \supset \mathcal{B}(\bar{y} + \bar{z}, (c - \ell)t) \text{ whenever } c \in (\ell, c') \text{ and } t \in (0, r/2).
\]

Employing this technique, we get short proofs of the results in [18]. Note that (50) does not mean that \(\text{sur} (F + G)(\bar{x}, \bar{y} + \bar{z}) = c - \ell\) since, given \((\bar{x}, \bar{w}) \in \text{gph}(F + G)\) close to \((\bar{x}, \bar{y} + \bar{z})\), there is no guarantee that \(\bar{w} = \bar{y} + \bar{z}\) for some pair \((\bar{y}, \bar{z})\) with the properties required above unless the so-called sum stability holds, cf. [18].

To conclude this section, we present a closely related result which was published in [1].
Theorem 4.7. Let \((X, \| \cdot \|)\) and \((Y, \| \cdot \|)\) be Banach spaces and a point \((\bar{x}, \bar{y}, \bar{z}) \in X \times Y \times Y\) be given. Consider set-valued mappings \(F, G : X \rightrightarrows Y\), with \((\bar{y}, \bar{z}) \in F(\bar{x}) \times G(\bar{x})\), for which there are positive constants \(a, b, \kappa,\) and \(\ell\) such that \(\kappa \ell < 1\); that both the sets \(\text{gph } F \cap (I B[\bar{x}, a] \times I B[\bar{y}, 2a])\) and \(\text{gph } G \cap (I B[\bar{x}, a] \times I B[\bar{z}, 2a])\) are closed; that
\[
\text{dist } (x, F^{-1}(y)) \leq \kappa \text{dist } (y, F(x)) \quad \text{for each } (x, y) \in I B(\bar{x}, a) \times I B(\bar{y}, a);
\]
and that
\[
G(x) \cap I B(\bar{z}, a) \subset G(x') + \ell \|x - x'\| I B_Y \quad \text{for each } x, x' \in I B(\bar{x}, a).
\]
Then, for any \(\beta > 0\) such that \(2\beta \max\{1, \kappa\} < a(1 - \kappa \ell)\), we have
\[
\text{dist } (\bar{x}, (F + G)^{-1}(y)) \leq \frac{\kappa}{1 - \kappa \ell} \text{dist } (y, F(\bar{x}) + \bar{z}) \quad \text{for each } y \in I B(\bar{y} + \bar{z}, \beta).
\]

Note that the property in (53) is stronger than semiregularity in general. For the Newton-type methods (cf. Section 5), the semiregularity is enough and seems to play the key role in the analysis.

5 Convergence of the Newton-type methods

In this section, we study inexact iterative methods of Newton type for solving the generalized equation (19). We focus on a local convergence analysis of (19) around a reference solution.

Theorem 5.1. Let \((X, \| \cdot \|)\) and \((Y, \| \cdot \|)\) be Banach spaces. Consider a point \(\bar{x} \in X\) along with a continuous mapping \(f : X \rightarrow Y\) and a set-valued mapping \(F : X \rightrightarrows Y\) with closed graph such that \(f(\bar{x}) + F(\bar{x}) \ni 0\). Suppose that there is \(\mathcal{H} : X \rightrightarrows \mathcal{L}(X, Y)\) which is upper semicontinuous at \(\bar{x} \in \text{int dom } \mathcal{H}\) with \(\chi(\mathcal{H}(\bar{x})) < \infty\), and such that, for each \(A \in \mathcal{H}(\bar{x})\), the mapping \(G_A : X \rightrightarrows Y\) defined by
\[
G_A(x) := f(\bar{x}) + A(x - \bar{x}) + F(x), \quad x \in X,
\]
is regular around \((\bar{x}, 0)\), and
\[
\lim_{x \rightarrow \bar{x}, \ x \neq \bar{x}} \frac{\sup_{A \in \mathcal{H}(\bar{x})} \|f(x) - f(\bar{x}) - A(x - \bar{x})\|}{\|x - \bar{x}\|} = 0.
\]
Let \((R_k)\) be a sequence of mappings \(R_k : X \times X \rightrightarrows Y\), \(k \in \mathbb{N}_0\), with closed graphs such that \((\bar{x}, \bar{x}) \in \text{int } (\bigcap_{k \in \mathbb{N}_0} \text{dom } R_k)\) and \(0 \in R_k(\bar{x}, \bar{x})\) for each \(k \in \mathbb{N}_0\), and assume that there are positive constants \(a, \gamma,\) and \(\ell\) satisfying
\[
\chi(\mathcal{H}(\bar{x})) + \ell + \gamma < \inf_{A \in \mathcal{H}(\bar{x})} \text{sur } G_A(\bar{x}, 0)
\]
such that
\[
\limsup_{x \rightarrow \bar{x}, \ x \neq \bar{x}} \frac{\sup_{k \in \mathbb{N}_0} \text{dist } (0, R_k(x, \bar{x}))}{\|x - \bar{x}\|} < \gamma,
\]

22
and that, for all $x$, $u$, $u' \in \mathcal{B}(\bar{x}, a)$ and all $k \in \mathbb{N}_0$, we have

$$R_k(x, u) \cap \mathcal{B}(0, a) \subset R_k(x, u') + \ell \|u - u'\| \mathcal{B}_Y. \quad (58)$$

Then there exist $t \in (0, 1)$ and $r > 0$ such that, for any starting point $x_0 \in \mathcal{B}(\bar{x}, r)$, there exists a sequence $(x_k)$ in $\mathcal{B}(\bar{x}, r)$ generated by (19) such that

$$\|x_{k+1} - \bar{x}\| \leq t \|x_k - \bar{x}\| \quad \text{for each} \quad k \in \mathbb{N}_0,$$

that is, $(x_k)$ converges q-linearly to $\bar{x}$.

**Proof.** Shrink $a$, if necessary, to guarantee that

$$\mathcal{B}(\bar{x}, a) \subset \text{dom } \mathcal{H} \quad \text{and} \quad \mathcal{B}(\bar{x}, a) \times \mathcal{B}(\bar{x}, a) \subset \text{dom } R_k \quad \text{for all} \quad k \in \mathbb{N}_0.$$

Let $c := \chi(\mathcal{H}(\bar{x}))$ and $m := \sup_{A \in \mathcal{H}(\bar{x})} \text{reg} G_A(\bar{x}, 0)$. By (56), there are $\mu > c$, $\kappa > m$, $\varepsilon > 0$, and $t \in (0, 1)$ satisfying

$$(\mu + \ell + \gamma + \varepsilon)\kappa < 1, \quad c + 2\varepsilon < \mu \quad \text{and} \quad \kappa(\gamma + \varepsilon) < t(1 - (\mu + \ell)\kappa). \quad (60)$$

**Step 1.** There exist $b \in (0, a)$ and $\theta \in (0, \kappa/(1 - \mu\kappa))$ such that, for every $A \in \mathcal{H}(\mathcal{B}(\bar{x}, b))$ and for every $(x, y) \in \mathcal{B}(\bar{x}, b) \times \mathcal{B}(0, b)$, we have

$$\text{dist} \left( x, G_A^{-1}(y) \right) \leq \theta \text{ dist} \left( y, G_A(x) \right).$$

As $\mathcal{H}$ is upper semicontinuous at $\bar{x}$, there is $\delta \in (0, a)$ such that

$$\mathcal{H}(x) \subset \mathcal{H}(\bar{x}) + \varepsilon \mathcal{B}_\mathcal{L}(x, y) \quad \text{for each} \quad x \in \mathcal{B}(\bar{x}, \delta). \quad (61)$$

From the definition of measure of noncompactness, we find a finite subset $\mathcal{A}$ of $\mathcal{H}(\bar{x})$ such that

$$\mathcal{H}(\bar{x}) \subset \mathcal{A} + (c + \varepsilon) \mathcal{B}_\mathcal{L}(x, y).$$

Therefore, given $x \in \mathcal{B}(\bar{x}, \delta)$, we have

$$\mathcal{H}(x) \subset \mathcal{A} + (c + \varepsilon) \mathcal{B}_\mathcal{L}(x, y) + \varepsilon \mathcal{B}_\mathcal{L}(x, y) = \mathcal{A} + (c + 2\varepsilon) \mathcal{B}_\mathcal{L}(x, y). \quad (61)$$

The second inequality in (60) implies that

$$\mathcal{H}(x) \subset \mathcal{A} + \mu \mathcal{B}_\mathcal{L}(x, y) \quad \text{for every} \quad x \in \mathcal{B}(\bar{x}, \delta). \quad (62)$$

Choose $\theta$ to satisfy

$$m/(1 - \mu m) < \theta < \kappa/(1 - \mu\kappa),$$

and then choose $\tau \in (m, \kappa)$ with $\tau/(1 - \mu\tau) < \theta$. Pick any $\bar{A} \in \mathcal{A}$ and $A \in \mu \mathcal{B}_\mathcal{L}(x, y)$. There exists $\alpha > 0$ such that

$$\text{dist} \left( x, G_A^{-1}(y) \right) \leq \tau \text{ dist} \left( y, G_A(x) \right) \quad \text{for all} \quad (x, y) \in \mathcal{B}(\bar{x}, \alpha) \times \mathcal{B}(0, \alpha).$$
The mapping $G_A$ has closed graph, because so does $F$. Let $g(x) := A(x - \bar{x})$, $x \in X$; then $G_{A+A} = G_A + g$. Observe that $g$ is single-valued, Lipschitz continuous with the constant $\mu$ such that $\mu \tau < 1$, and $g(\bar{x}) = 0$. We can apply [13, Theorem 5G.3] with $F := G_A$, $y = 0$, $a = b := \alpha$, $\kappa := \tau$, and $\kappa' := \theta$, obtaining that there is $\beta = \beta(\bar{A}) > 0$, independent of $A$, such that the following claim holds: for each $y, y' \in B[0, \beta]$ and each $x \in (G_{A+A})^{-1}(y') \cap B[\bar{x}, 2\theta \beta]$, there is $x' \in (G_{A+A})^{-1}(y)$ satisfying $\|x - x'\| \leq \theta \|y - y'\|$.

We show that, for each $(x, y) \in B(\bar{x}, \theta \beta / 3) \times B(0, \beta / 3)$, we have

$$\text{dist} \left( x, (G_{A+A})^{-1}(y) \right) \leq \theta \text{dist} \left( y, G_{A+A}(x) \right).$$

To see this, fix any such a pair $(x, y)$. Pick an arbitrary $y' \in G_{A+A}(x)$ (if there is any). If $\|y'\| \leq \beta$, then the claim yields $x' \in (G_{A+A})^{-1}(y)$ with $\|x - x'\| \leq \theta \|y - y'\|$, and consequently,

$$\text{dist} \left( x, (G_{A+A})^{-1}(y) \right) \leq \|x - x'\| \leq \theta \|y - y'\|.$$

On the other hand, assuming that $\|y'\| > \beta$, we have $\|y' - y\| > \beta - \beta / 3 = 2\beta / 3$. Then, using the claim with $(x, y')$ replaced by $(\bar{x}, 0)$, we find $x' \in (G_{A+A})^{-1}(y)$ such that $\|\bar{x} - x'\| \leq \theta \|y\|$. Consequently,

$$\text{dist} \left( x, (G_{A+A})^{-1}(y) \right) \leq \|x - \bar{x}\| + \text{dist} \left( \bar{x}, (G_{A+A})^{-1}(y) \right) \leq \|x - \bar{x}\| + \|\bar{x} - x'\| < \theta \beta / 3 + \theta \beta / 3 = \theta (2\beta / 3) < \theta \|y - y'\|.$$

Since $y' \in G_{A+A}(x)$ is arbitrary, (63) is proved.

Summarizing, given $\bar{A} \in A$, there exists $\beta := \beta(\bar{A}) > 0$ such that, for each $A \in \mu B_{L(X,Y)}$ and each $(x, y) \in B(\bar{x}, \theta \beta / 3) \times B(0, \beta / 3)$, inequality (63) holds. Taking into account (62), one has $H(B(\bar{x}, \delta)) \subset A + \mu B_{L(X,Y)}$. Letting $b = \min_{\bar{A} \in A} \{ \delta, \beta(\bar{A}) / 3, \theta \beta(\bar{A}) / 3 \}$, we finish the proof of this step.

**Step 2.** There exists $r > 0$ such that, for each $x \in B(\bar{x}, r)$, each $A \in H(x)$, and each $k \in \mathbb{N}_0$, there is $x' \in B(\bar{x}, r)$ such that

$$(f(x) + A(x' - x) + F(x')) \cap R_k(x, x') \neq \emptyset \quad \text{and} \quad \|x' - \bar{x}\| \leq t \|x - \bar{x}\|.$$

Let $b$ and $\theta$ be the constants found in Step 1. Using (55) and (57), we find a constant $\delta \in (0, b/(1 + \gamma))$ such that, for every $x \in B(\bar{x}, \delta) \setminus \{\bar{x}\}$ and every $k \in \mathbb{N}_0$, we have

$$\sup_{A \in H(x)} \|f(x) - f(\bar{x}) - A(x - \bar{x})\| < \varepsilon \|x - \bar{x}\| \quad \text{and} \quad \text{dist} \left( 0, R_k(x, \bar{x}) \right) < \gamma \|x - \bar{x}\|.$$

The first inequality in (60) implies that $\theta \ell < \kappa \ell / (1 - \mu \kappa) < 1$. Let $r \in (0, \delta)$ be such that

$$r < \frac{\delta (1 - \theta \ell)}{2(\varepsilon + \gamma) \max \{1, \theta \}}.$$

Fix an arbitrary $x \in B(\bar{x}, r)$. Choose any $A \in H(x)$ and $k \in \mathbb{N}_0$. If $x = \bar{x}$, then, setting $x' := \bar{x}$, we are done because $0 \in R_k(x, \bar{x})$ and $0 \in f(\bar{x}) + F(\bar{x})$. Assume that $x \neq \bar{x}$. By (64) we find $\bar{z} \in -R_k(x, \bar{x})$ such that $\|\bar{z}\| < \gamma \|x - \bar{x}\|$. Then

$$B(\bar{z}, \delta) \subset B(0, (1 + \gamma) \delta) \subset B(0, b) \subset B(0, a).$$
Consequently, for all \(u, u' \in B(\bar{x}, \delta)\), we have
\[
(-R_k(x, u)) \cap B(\bar{z}, \delta) \subset (-R_k(x, u)) \cap B(0, a) = -(R_k(x, u) \cap B(0, a))
\]
\[
\subset -(R_k(x, u') + \ell\|u - u'\|B_Y) = -R_k(x, u') + \ell\|u - u'\|B_Y.
\]
From Step 1 we get
\[
dist\left(u, G_A^{-1}(v)\right) \leq \theta dist\left(v, G_A(u)\right) \quad \text{for all} \quad (u, v) \in B(\bar{x}, \delta) \times B(0, \delta).
\]
As \(\theta\ell < 1\), applying Theorem 4.7 with \((F, G, \bar{y}, a, \kappa, \beta)\) replaced by \((G_A, -R_k(x, \cdot), 0, \delta, (\varepsilon + \gamma)r)\), we get
\[
\text{(65)} \quad \text{dist} \left(\bar{x}, (G_A - R_k(x, \cdot))^{-1}(y)\right) \leq \frac{\theta}{1 - \theta\ell}\|y - \bar{z}\| \quad \text{for all} \quad y \in B(\bar{z}, (\varepsilon + \gamma)r).
\]
Set
\[
\text{(66)} \quad y := f(\bar{x}) - f(x) + A(x - \bar{x}).
\]
If \(y = \bar{z}\), then \(f(x) + A(\bar{x} - x) - f(\bar{x}) \in R_k(x, \bar{x}) \cap (f(x) + A(\bar{x} - x) + F(x))\), and setting \(x' := \bar{x}\) we are done. Assume that \(y \neq \bar{z}\). The first inequality in (64) and the choice of \(\bar{z}\) imply that
\[
0 < \|y - \bar{z}\| \leq \|f(x) - f(\bar{x}) - A(x - \bar{x})\| + \|\bar{z}\| < (\varepsilon + \gamma)\|x - \bar{x}\| < (\varepsilon + \gamma)r.
\]
Remembering that \(\theta < \kappa/(1 - \mu\kappa)\) and \(\kappa\ell/(1 - \mu\kappa) < 1\), and using the last inequality in (60), we get
\[
\frac{\theta}{1 - \theta\ell} < \frac{\frac{\kappa}{1 - \mu\kappa}}{\frac{\kappa}{1 - (\mu + \ell)\kappa}} < \frac{t}{\gamma + \varepsilon}.
\]
This and (65) imply that there is \(x' \in (G_A - R_k(x, \cdot))^{-1}(y)\) such that
\[
\|x' - \bar{x}\| < \frac{t}{\gamma + \varepsilon}\|y - \bar{z}\| < \frac{t}{\varepsilon + \gamma}(\varepsilon + \gamma)\|x - \bar{x}\| = t\|x - \bar{x}\|.
\]
Hence, \(\|x' - \bar{x}\| < r\) because \(t \in (0, 1)\) and \(x \in B(\bar{x}, r)\). The choice of \(y\) implies that
\[
f(\bar{x}) - f(x) + A(x - \bar{x}) \in G_A(x') - R_k(x, x') = f(\bar{x}) + A(x' - \bar{x}) + F(x') - R_k(x, x').
\]
Therefore \(0 \in f(x) + A(x' - x) + F(x') - R_k(x, x')\), which means that \((f(x) + A(x' - x) + F(x')) \cap R_k(x, x') \neq \emptyset\). The proof of Step 2 is finished.

To conclude the proof, let \(r > 0\) be the constant found in Step 2. Consider the iteration (19) and choose any \(k \in \mathbb{N}_0, x_k \in B(\bar{x}, r)\) and \(A_k \in H(x_k)\). Apply Step 2 with \(A := A_k\) and \(x := x_k\), and set \(x_{k+1} := x'\). Then \(x_{k+1}\) satisfies (19) and (59). It remains to choose any \(x_0 \in B(\bar{x}, r)\) to obtain this way an infinite sequence \((x_k)\) in \(B(\bar{x}, r)\) generated by (19) and satisfying (59) for all \(k \in \mathbb{N}_0\). Since \(t \in (0, 1)\), \((x_k)\) converges linearly to \(\bar{x}\). □
Remark 5.2. If (57) is replaced by a stronger condition
\[ \lim_{x \to \bar{x}, x \neq \bar{x}} \sup_{k \in \mathbb{N}_0} \text{dist} \left( 0, R_k(x, \bar{x}) \right) = 0, \]
then there is \( r > 0 \) such that, for any starting point \( x_0 \in B(\bar{x}, r) \), there exists a sequence \( (x_k) \) in \( B(\bar{x}, r) \) generated by (19) such that \( (x_k) \) converges q-super-linearly to \( \bar{x} \), that is, if there is \( k_0 \in \mathbb{N} \) such that \( x_k \neq \bar{x} \) for all \( k > k_0 \) then \( \lim_{k \to \infty} \|x_{k+1} - \bar{x}\|/\|x_k - \bar{x}\| = 0 \). Indeed, in (60) both the constants \( \varepsilon \) and \( \gamma \), and consequently, also \( t \) can be chosen arbitrarily small.

Suppose that \( X := \mathbb{R}^n \), \( Y := \mathbb{R}^m \), and \( f \) is locally Lipschitz continuous. We can take, for example, Clarke’s generalized Jacobian or Bouligand’s limiting Jacobian as \( H \). Then \( H \) is upper semicontinuous and condition (55) is satisfied when \( f \) is semismooth at \( \bar{x} \) (with respect to the corresponding Jacobian). Moreover, \( \chi(H(\bar{x})) = 0 \). If, in addition, \( F \equiv 0 \) and \( R_k \equiv 0 \) for each \( k \in \mathbb{N}_0 \), then the assumption of regularity of all mappings \( G_A \) in (54) is nothing else but the requirement that all matrices in \( H(\bar{x}) \) have full-rank \( m \), and we arrive at the classical result for semismooth Newton-type methods (see, for example, [6, 40, 21, 1, 8, 7, 39]).

In [1], the following iterative process was studied: Choose a sequence of set-valued mappings \( A_k : X \times X \rightrightarrows Y \) and a starting point \( x_0 \in X \), and generate a sequence \( (x_k) \) in \( X \) by taking \( x_{k+1} \) to be a solution to the auxiliary inclusion
\[ 0 \in A_k(x_{k+1}, x_k) + F(x_{k+1}) \quad \text{for each} \quad k \in \mathbb{N}_0. \]

Theorem 4.1 therein for iteration (67) is quite similar to Theorem 5.1 above with one important difference. We assume that all the “partial linearizations” \( G_A \) in (54) are regular around \((\bar{x},0)\), while in [1] the mapping \( f + F \) is assumed to be such. Clearly, our assumption is weaker. Indeed take, for example, \( f(x) := |x|, x \in \mathbb{R}, F \equiv 0, \) and \( H(x) := x/|x| \) if \( x \neq 0 \) and \( H(0) := \{-1,1\} \). Then \( f \) is not even semiregular at 0 while \( H \) satisfies all the assumptions in Theorem 5.1.
