I. THE KOCHEN-SPECKER THEOREM

The Kochen-Specker (KS) theorem \[1, 2, 3\] shows one of the most fundamental features of quantum mechanics (QM): measurements do not reveal preexisting values. More precisely, it asserts that any hidden variable theory that satisfies QM must be contextual (i.e., the predefined results must change depending on which other compatible measurements are performed).

Its original mathematical proof \[2\] is based on the observation that, for a physical system described in QM by a Hilbert space of dimension \(d \geq 3\), it is possible to find a set of \(n\) projection operators \(P_i\) which represent yes-no questions about the physical system so that none of the \(2^n\) possible sets of “yes” or “no” answers is compatible with the sum rule of QM for orthogonal resolutions of the identity (i.e., if the sum of a subset of mutually orthogonal projection operators is the identity, one and only one of the corresponding answers ought to be “yes”) \[1\]. Yes-no questions can also be represented by the vectors \(v_i\) onto which \(P_i\) projects. \(v_i\) can be assumed to belong to \(S^{d-1}\), the unit sphere in \(\mathbb{R}^d\). If there are predefined noncontextual yes-no answers, then there will exist a function \(f: S^{d-1} \rightarrow \{0, 1\}\) such that

\[
\sum_{i=1}^{d} f(v_i) = 1 \quad \text{whenever} \quad \sum_{i=1}^{d} P_i = \mathbb{1}, \tag{1}
\]

where \(\{P_i\}_{i=1}^{d}\) is a set of orthogonal projectors and \(\mathbb{1}\) denotes the identity, \(f(v_i) = 1\) means that the predefined answer to the yes-no question represented by \(P_i\) is “yes,” and \(f(v_i) = 0\) means that the answer to \(P_i\) is “no.” If such a function exists for a given set of vectors, it is said that the set is “KS-colorable”; if it does not exist, then it is said that the set is “KS-uncolorable” and serves as a proof of the KS theorem. The original proof \[2\] consists of a KS-uncolorable set of 117 vectors in \(S^2\). The smallest proofs currently known have 31 vectors in \(S^2\) \[1\] and 18 vectors in \(S^3\) \[1, 2\].

A simple physical interpretation of the projection operator \(P_i\) onto \(v_i \in S^2\) can be given in terms of the spin components along \(v_i\) of a spin-1 particle. Using a suitable representation for \(J_x, J_y,\) and \(J_z\) \[1\], the relation

\[
P_i = \mathbb{1} - \frac{J_i^2}{\hbar^2} \tag{2}
\]

defines a one-to-one correspondence between the projector \(P_i\) onto \(v_i\) and the square of the spin component along \(v_i\), denoted by \(J_i^2\). Therefore, a measurement of \(P_i\) represents the yes-no question “does the square of the spin component along \(v_i\) equal zero?” The eigenvalue 1 corresponds to the answer “yes,” and the degenerate eigenvalues 0 to the answer “no.” The operators \(J_1^2, J_2^2, J_3^2\) (or any other three squares of spin components along three orthogonal directions) commute, so that the corresponding observables can be measured simultaneously.

In addition, since

\[
J_1^2 + J_2^2 + J_3^2 = 2\hbar^2 \mathbb{1}, \tag{3}
\]

then QM predicts that the results of measuring observables \(J_1^2, J_2^2, J_3^2\) must be one 0 and two \(\hbar^2\). Analogously, the projectors \(P_x, P_y, P_z\) commute, so that the corresponding yes-no questions can be measured simultaneously. Using Eq. (2), Eq. (3) becomes

\[
P_x + P_y + P_z = \mathbb{1}. \tag{4}
\]

Therefore, according to QM, the answers to \(P_x, P_y, P_z\) must be one “yes” (represented by 1) and two “no” (represented by 0).

The fact that a function \(f: S^2 \rightarrow \{0, 1\}\) satisfying the condition (1) does not exist means that all \(P_i\) \((J_i^2)\) cannot have predefined answers (values) compatible with relation (1) \([1, 2]\).

II. PROOFS OF “NULLIFICATION”

Godsil and Zaks \[8\] have shown that the three-dimensional rational unit sphere \(S^2 \cap \mathbb{Q}^3\) can be colored using only three colors such that orthogonal vectors are differently colored. A corollary of this result has
been recently used by Meyer to show that $S^2 \cap \mathbb{Q}^3$ is KS-colorable. Therefore, one can assign predefined answers if one is restricted to those $P_i$ which project onto $\hat{v}_i \in S^2 \cap \mathbb{Q}^3$. The set $S^2 \cap \mathbb{Q}^3$ is dense in $S^2$ and therefore vectors in $S^2 \cap \mathbb{Q}^3$ cannot be distinguished from those in $S^2$ by finite-precision measurements. This leads Meyer to conclude that “finite-precision measurement nullifies the Kochen-Specker theorem”.

Kent has shown that dense KS-colorable sets exist in any arbitrary finite-dimensional real or complex Hilbert space. This leads him to conclude that “non-contextual hidden variable (NCHV) theories cannot be excluded by theoretical arguments of the KS type once the imprecision in real world measurements is taken into account”. More recently, Clifton and Kent have constructed a NCHV model for any finite-dimensional Hilbert space that they claim is consistent with all the statistical predictions of QM. This allows them to conclude that “all the predictions of nonrelativistic QM that are verifiable to within any finite precision can be simulated classically by NCHV theories”.

In response, Ax and Kochen have argued that the study of the effect of finite-precision measurements on the KS theorem requires a different formalization which is still missing. In there is a criticism of the physical interpretation of the existence of KS-colorable sets. Havlicek et al. have argued that any possible KS coloring of the rational unit sphere is not physically satisfactory. Mermin has argued that the continuity of probabilities under slight changes in the experimental configuration weighs against the conclusions in . Appleby has expanded on Mermin’s discussion and argued that in the models of Meyer, Kent, and Clifton the very existence of an observable is contextual and measurements do not reveal preexisting classical information.

In this paper I shall prove that any possible KS coloring of the rational unit sphere of the type proposed in leads to predictions which differ from those of QM and, therefore, that any NCHV theory which assigns definite colors to the rational unit sphere can be discarded on experimental grounds even if finite-precision measurements are used. In addition, I shall prove that any possible KS coloring of a dense set of the kind proposed by Clifton and Kent also leads to predictions that differ from those of QM, and therefore explicit NCHV models like those in can also be discarded on experimental grounds.

Both proofs are inspired by a lesser known type of proof of the KS theorem which does not require an entire KS-uncolorable set but only one of its subsets. In particular, it is based on a proof by Stairs which only requires eight of the vectors of the 117-vector KS-uncolorable set in . This eight-vector set appears for the first time in . Stairs’ proof was reformulated by Clifton .

The strategy of both proofs is as follows. First we show that any NCHV theory cannot assign the value 1 to certain vectors in the set which is assumed to have predefined values. We then show that the impossibility of such an assignment leads to an inequality valid for any NCHV theory but which is violated by QM.

### III. KS Colorings of the Rational Sphere Are Incompatible with QM

Consider the following vectors of the rational unit sphere:

$$\hat{A} = (0, c_A, -s_A),$$

$$\hat{B} = (c_B, s_B, 0),$$

$$\hat{C} = (c_{CD} + \hat{N}_A s_D, s_A c_D, D s_A c_{CD}),$$

where $s_i = (1 - c_i^2)^{1/2}$, $i$ being $A$, $B$, $C$, or $D$, $N = [c_A^2 + (s_A c_D)^2]^{-1/2}$, and $(c_i, s_i, N) \in \mathbb{Q}$.

**Lemma 1.** There is no KS coloring of the rational unit sphere $S^2 \cap \mathbb{Q}^3$ in which $f(\hat{A}) = f(\hat{B}) = f(\hat{C}) = 1$.

**Proof via a reductio ad absurdum.** Consider the following additional vectors $\hat{v}_i \in S^2 \cap \mathbb{Q}^3$:

$$\hat{v}_1 = (1, 0, 0),$$

$$\hat{v}_2 = N (c_A s_D, s_A c_D, c_A c_D),$$

$$\hat{v}_3 = (0, 0, 1),$$

$$\hat{v}_4 = N (s_A c_D, -c_A, s_A c_D^2),$$

$$\hat{v}_5 = (0, 1, 0),$$

$$\hat{v}_6 = (c_D, 0, -s_D).$$

If $f(\hat{A}) = 1 \Rightarrow f(\hat{v}_1) = f(\hat{v}_2) = 0$, if $f(\hat{B}) = 1 \Rightarrow f(\hat{v}_3) = 0$, and if $f(\hat{C}) = 1 \Rightarrow f(\hat{v}_4) = 0$. In addition, if $f(\hat{v}_1) = f(\hat{v}_4) = 0 \Rightarrow f(\hat{v}_5) = 1$ and if $f(\hat{v}_2) = f(\hat{v}_6) = 0 \Rightarrow f(\hat{v}_6) = 1$. However, $f(\hat{v}_5) = 1$ is incompatible with $f(\hat{v}_6) = 1$ since $\hat{v}_5$ and $\hat{v}_6$ are orthogonal.

Let us consider an ensemble of spin-1 particles and let us assume that any particle has a definite color (1 or 0) for every vector of the rational unit sphere and in particular for $\hat{A}$, $\hat{B}$, and $\hat{C}$. Let $P(B)$ be the probability of finding a particle with $f(\hat{B}) = 1$ in such an ensemble, $P(A \land B \land C)$ be the probability of finding $f(\hat{A}) = f(\hat{B}) = f(\hat{C}) = 1$, $P(A \land B \land \neg C)$ be the probability of finding $f(\hat{A}) = f(\hat{B}) = 1$ and $f(\hat{C}) = 0$, and $P(A|B)$ be the probability of finding $f(\hat{A}) = 1$ if $f(\hat{B}) = 1$. Note that such probabilities make sense in a NCHV theory but not in QM. From the point of view of a NCHV theory, $P(A|B)$ can be obtained by means of two alternative but equivalent methods: either preparing the particles in a quantum eigenstate of the square of the spin component along $\hat{B}$ with eigenvalue 0, measuring the square of the spin along $\hat{A}$, and counting the number of events in which the eigenvalue 0 has been obtained, or preparing the particles in pairs in the singlet state, measuring the square of the spin along $\hat{B}$ in one of the particles and the square of the spin along $\hat{A}$.
Lemma 2. There is no KS coloring \( \mathcal{I} \) of the rational unit sphere \( S^2 \cap \mathbb{Q}^3 \) compatible with all the statistical predictions of QM.

**Proof.** The following inequality must be satisfied in any NCHV theory:

\[
P(B) \geq P(A \wedge B \wedge \neg C) + P(\neg A \wedge B \wedge C) \tag{14}
\]

Lemma 1 shows that

\[
P(A \wedge B \wedge C) = 0. \tag{15}
\]

Therefore, the inequality (14) can be written as

\[
P(B) \geq P(A \wedge B) + P(B \wedge C), \tag{16}
\]

which is equivalent to

\[
P(B) \geq P(B)P(A|B) + P(B)P(C|B). \tag{17}
\]

Inequality (17) can be simplified to

\[
1 \geq P(A|B) + P(C|B). \tag{18}
\]

Let us define

\[
F_{\text{NCHV}} = P(A|B) + P(C|B). \tag{19}
\]

Then, according to inequality (15), any NCHV theory will predict

\[
F_{\text{NCHV}} \leq 1. \tag{20}
\]

On the other hand, in QM the equivalent of Eq. (19) is

\[
F_{\text{QM}} = \left| \langle \hat{A}|\hat{B} \rangle \right|^2 + \left| \langle \hat{C}|\hat{B} \rangle \right|^2. \tag{21}
\]

In particular, if we choose

\[
e_A = \frac{104}{185}, \tag{22}
\]

\[
e_B = \frac{10209400000}{12605796209}, \tag{23}
\]

\[
e_C = 0.405, \tag{24}
\]

\[
e_D = 0.371, \tag{25}
\]

then we obtain

\[
F_{\text{QM}} = 1.108, \tag{26}
\]

which contradicts the prediction of NCHV theories given by inequality (24) and (26).

**Lemma 3.** Given an ensemble of systems such that, for every system described by \( \mathcal{D} \), the probability of finding an individual system in which a KS coloring \( \mathcal{I} \) satisfies \( f(\hat{A}') = f(\hat{B}') = 1 \) is infinitesimally close to zero if such coloring must simulate the predictions of QM.

**Proof.** Consider six additional vectors \( \hat{v}'_i \in \mathcal{D} \) such that \( \hat{v}'_1 \) and \( \hat{v}'_2 \) are both infinitesimally close to being orthogonal to \( \hat{A}' \); \( \hat{v}'_3 \) and \( \hat{v}'_4 \) are both infinitesimally close to being orthogonal to \( \hat{B}' \); \( \hat{v}'_3, \hat{v}'_4, \) and \( \hat{v}'_5 \) are mutually orthogonal; \( \hat{v}'_2, \hat{v}'_3, \) and \( \hat{v}'_4 \) are mutually orthogonal; \( \hat{v}'_5 \) and \( \hat{v}'_6 \) are infinitesimally close to being orthogonal. The fact that eight vectors with the above properties exist in \( \mathcal{D} \in S^2 \) is not excluded in \( \mathcal{I} \). Since \( f \) must simulate the predictions of QM, if \( f(\hat{A}') = 1 \), then the probability of \( f(\hat{v}'_i) = 1 \) must be \( \left| \langle \hat{v}'_i|\hat{A}' \rangle \right|^2 \), that is, infinitesimally close to zero, because \( \hat{A}' \) and \( \hat{v}'_i \) are infinitesimally close to being orthogonal. The same argument states that if \( f(\hat{A}') = 1 \), the probability of \( f(\hat{v}'_2) = 1 \) must be infinitesimally close to zero. Therefore, if \( f(\hat{A}') = 1 \), then

\[
f(\hat{v}'_i) = f(\hat{v}'_2) = 0 \quad \text{for almost every system of an ensemble.}
\]

Using the same reasoning, if \( f(\hat{B}') = 1 \), then

\[
f(\hat{v}'_3) = f(\hat{v}'_4) = 0 \quad \text{for almost every system of an ensemble.}
\]

In addition, if \( f(\hat{v}'_i) = f(\hat{v}'_2) = 0 \Rightarrow f(\hat{v}'_5) = 1 \) and if

\[
f(\hat{v}'_2) = f(\hat{v}'_4) = 0 \Rightarrow f(\hat{v}'_6) = 1.
\]

Since \( f \) must simulate
the predictions of QM, if \( f(\hat{v}_5) = 1 \), then the probability of \( f(\hat{v}_5) = 1 \) must be \( |\langle \hat{v}_5 | \hat{v}_5 \rangle|^2 \), that is, infinitesimally close to zero, because \( \hat{v}_5 \) and \( \hat{v}_6 \) are infinitesimally close to being orthogonal \([25]\).

**Lemma 4.** There is no KS coloring \([1]\) of \( D \in S^2 \) compatible with all the statistical predictions of QM.

**Proof.** I will use the same notation used in the proof of Lemma 2. According to Lemma 3, in any NCHV theory

\[
P(A' \land B') \approx 0. \tag{27}
\]

However, according to QM,

\[
|\langle \hat{A}' | \hat{B}' \rangle|^2 \approx \frac{1}{9}. \tag{28}
\]

V. CONCLUSION

The reason why dense sets in \([9, 10, 11]\) do not lead to NCHV theories that simulate QM can be summarized as follows: most of the many possible KS colorings of these sets must be statistically irrelevant in order to reproduce some of the statistical predictions of QM. Then, the remaining statistically relevant KS colorings cannot reproduce some different statistical predictions of QM. I therefore conclude that the existence of KS-colorable sets that are dense in the corresponding Hilbert spaces, like those in \([9, 11, 11]\), does not lead by itself to a NCHV theory capable of eluding statistical KS-type proofs, and must therefore not be interpreted as a nullification of the physical impact of the KS theorem once the finite-precision of measurements is taken into account.

[26] If we were not restricted to rational vectors, then the maximum contradiction would occur when \( F_{QM} = 1.172 \), as can be numerically found. Moreover, if we were not restricted to rational vectors, we could choose \( B = C \) while preserving the remaining orthogonalities and then the maximum contradiction would occur when \( F_{QM} = \frac{1}{2} + 1 \) (see Refs. \([21, 22, 23, 24, 25]\)).
[27] For instance, \( \hat{v}_1 \approx \frac{1}{\sqrt{2}} (0, 1, -1) \), \( \hat{v}_2 \approx \frac{1}{\sqrt{2}} (1, 0, -1) \), \( \hat{v}_3 \approx \frac{1}{\sqrt{2}} (0, 1, 1) \), \( \hat{v}_4 \approx \frac{1}{\sqrt{2}} (1, 0, 1) \), \( \hat{v}_5 \approx (0, 1, 0) \), and \( \hat{v}_6 \approx (0, 0, 0) \).
[28] R. Clifton (private communication) sees no reason to accept that if \( \hat{v}_5 \) and \( \hat{v}_6 \) are infinitesimally close to being orthogonal and have predefined values, then, in any NCHV theory which simulates QM, the systems for which \( f(\hat{v}_5) = f(\hat{v}_6) = 1 \) must constitute a statistically irrelevant subensemble of the whole ensemble of systems. He accepts that this is the case if the ensemble was prepared in the quantum state \( |\hat{v}_5\rangle \). However, there is an experimental reason that supports the above assumption: from
the point of view of a NCHV theory, even if the ensemble is prepared in an arbitrary quantum state, any joint measurement along $\hat{v}_5'$ and $\hat{v}_6'$ (which are as close as one desires to being compatible observables) has a nonzero probability (which increases along with the experiment's precision) to reveal their predefined values. Experimentally, the probability of “revealing” $f(\hat{v}_5') = f(\hat{v}_6') = 1$ has been found to be very close to zero, even if the ensemble has not been prepared in the state $|\hat{v}_5'\rangle$.
