Abstract

Standard Model (SM) CP asymmetries in $B \rightarrow K\ell^+\ell^-$ are expected to be very small. This feature could help in the understanding of new physics scenarios which predict the existence of CP odd phases in various Wilson coefficients. In this paper we have analyzed the $B \rightarrow K\ell^+\ell^-$ decay in beyond the SM scenarios where the Wilson coefficients have new CP odd phases. The sensitivity of the CP asymmetries on these new weak phases is discussed.

1 Introduction

One of the key ingredients in the Standard Model (SM) is CP violation, which can be described by the Cabibbo-Kobayashi-Maskawa (CKM) matrix[1]. However, even with this description we still have an incomplete picture concerning the origin of CP violation in the SM. The exploitation of CP violation from the theoretical and experimental sides of physics is very exciting, as it may open a window to the existence of new physics beyond the SM. Note that the existence of CP violation is a well established fact in $K[2]$ and $B[3]$ meson systems.

In order to study the sources of CP violation it is promising to consider those observables which are sensitive to the possible CP phases. For example, CP asymmetries in decay widths and lepton polarization asymmetries, such as explored in references [4–7].

One of the promising directions for measuring CP violation is the analysis of rare semi-leptonic decays. From the experimental perspective the exclusive decay modes, such as $B \to K \ell^+ \ell^-$ and $B \to K^* \ell^+ \ell^-$, are easy to measure. Two years ago the Belle[8] and BaBar[9] collaborations announced the following results for the branching ratios for the $B \to K \ell^+ \ell^-$ and $B \to K^* \ell^+ \ell^-$ decays;

$$Br(B \to K \ell^+ \ell^-) = \begin{cases} 
(4.8^{+1.0}_{-0.9} \pm 0.3 \pm 0.1) \times 10^{-7} & [8], \\
(0.65^{+0.14}_{-0.13} \pm 0.04) \times 10^{-6} & [9],
\end{cases}$$

$$Br(B \to K^* \ell^+ \ell^-) = \begin{cases} 
(11.5^{+2.6}_{-3.4} \pm 0.8 \pm 0.2) \times 10^{-7} & [8], \\
(0.88^{+0.23}_{-0.29}) \times 10^{-6} & [9].
\end{cases}$$

The analysis for study of possible CP violation in $B \to K^* \ell^+ \ell^-$ was done in earlier works [10, 11]. The goal of our present work is to similarly study the possible CP violation asymmetry in the exclusive $B \to K \ell^+ \ell^-$ decay using the most general form of the effective Hamiltonian, including all possible forms of interactions. Such an analysis will be useful for comparisons with experimental results, as the inclusive modes are generally hard to measure. Note that the CP violation in the decay $B \to K \ell^+ \ell^-$ is induced by the $b \to s \ell^+ \ell^-$ transition, which in the SM is practically equal to zero. This is due to the CKM factors $V_{ub}V_{us}^*$ being negligible, with the result that the unitarity condition produces only an overall phase factor in the matrix element. Therefore the CP asymmetry is strongly suppressed. As such, any deviation from zero for the CP asymmetry would be an indication of new physics.

This paper is organized as follows. In section 2, using the most general form of the effective Hamiltonian, we derive the matrix element of the $B \to K \ell^+ \ell^-$ decay in terms of the $B \to K$ transition form-factors. We also derive in this section the general analytic expression for the CP
The last two terms, with the coefficients $C_{\mu}$ which are parameterized in terms of form-factors which depend on the momentum transfer squared, describe the sum of the contributions from the SM and the new physics, where they can be written as;

$$H_{eff} = \frac{\alpha G_F}{\sqrt{2}\pi} V_{tb} V_{ts}^* \left[ C_{SL} \left( \bar{s}i\sigma_{\mu\nu} \frac{q^\nu}{q^2} Lb \right) \bar{\ell}_\gamma \mu \ell + C_{BR} \left( \bar{s}i\sigma_{\mu\nu} \frac{q^\nu}{q^2} Rb \right) \bar{\ell}_\gamma \mu \ell \right.$$

$$+ C_{LL}^{tot} (\bar{s}L_\gamma \mu \ell L) \bar{\ell}_L \gamma \mu \ell + C_{LR}^{tot} (\bar{s}L_\gamma \mu \ell L) \bar{\ell}_R \gamma \mu \ell + C_{RL} (\bar{s}R_\gamma \mu \ell R) \bar{\ell}_L \gamma \mu \ell$$

$$+ C_{RR} (\bar{s}R_\gamma \mu \ell R) \bar{\ell}_R \gamma \mu \ell + C_{LRLR} (\bar{s}L_\ell \ell R) \bar{\ell}_L \ell + C_{RLLR} (\bar{s}R_\ell \ell R) \bar{\ell}_R \ell + C_{TE} \bar{s}\sigma_{\mu\nu} b \ell \sigma^{\mu\nu} \ell$$

$$+ i C_{TE} \epsilon^{\mu\alpha\beta} \bar{s}\sigma_{\mu\nu} b \ell \sigma_{\alpha\beta} \ell \right] , \quad (1)$$

where $L/R = \frac{1}{2}(1 \mp \gamma_5)$, the $C_{\alpha}$'s are the Wilson coefficients of the four-Fermi interactions and $q_\mu = (p_B - p_K)_\mu = (p_+ + p_-)_\mu$ is the momentum transfer. Among the twelve Wilson coefficients several already exist in the SM. For example, the first two terms with coefficients $C_{SL}$ and $C_{BR}$ describe the penguin operators, where in the SM these coefficients are equal to $-2m_b C_{7}^{eff}$ and $-2m_b C_{7}^{eff}$. The next four terms in Eq.(1) are the vector type interactions with coefficients $C_{LL}^{tot}$, $C_{LR}^{tot}$, $C_{RL}$ and $C_{RR}$. Two of these vector interactions, $C_{LL}^{tot}$ and $C_{LR}^{tot}$, also exist in the SM with the form $(C_9^{eff} - C_{10})$ and $(C_9^{eff} + C_{10})$. Therefore we can say that the coefficients $C_{LL}^{tot}$ and $C_{LR}^{tot}$ describe the sum of the contributions from the SM and the new physics, where they can be written as;

$$C_{LL}^{tot} = C_9^{eff} - C_{10} + C_{LL} ,$$

$$C_{LR}^{tot} = C_9^{eff} + C_{10} + C_{LR} .$$

The terms with coefficients $C_{LRLR}$, $C_{RLLR}$, $C_{LRLL}$ and $C_{RLRL}$ describe the scalar type interactions. The last two terms, with the coefficients $C_{TE}$ and $C_{TE}$, describe the tensor type interactions.

Now that we have the effective Hamiltonian, describing the $b \rightarrow s\ell^+\ell^-$ decay at a scale $\mu \approx m_B$, we can write down the matrix elements for the $B \rightarrow K\ell^+\ell^-$ decay. The matrix element for this decay can be obtained by sandwiching the effective Hamiltonian between $B$ and $K$ meson states; which are parameterized in terms of form-factors which depend on the momentum transfer squared,
\( q^2 = (p_B - p_K)^2 = (p_+ - p_-)^2 \). It follows from Eq.(1) that in order to calculate the amplitude of the \( B \to K\ell^+\ell^- \) decay the following matrix elements are required:

\[
\langle K | \bar{s}_\gamma b | B \rangle, \langle K | \bar{s}\sigma_{\mu\nu}q^\nu b | B \rangle, \langle K | \bar{s}b | B \rangle, \langle K | \bar{s}\sigma_{\mu\nu}b | B \rangle.
\]

These matrix elements are defined as follows [14–16]:

\[
\langle K(p_K) | \bar{s}_\gamma b | B(p_B) \rangle = f_+ \left[ (p_B + p_K)_\mu - \frac{m_B^2 - m_K^2}{q^2} q_\mu \right] + f_0 \frac{m_B^2 - m_K^2}{q^2} q_\mu.
\] (2)

\[
\langle K(p_K) | \bar{s}\sigma_{\mu\nu}b | B(p_B) \rangle = -i \frac{f_T}{m_B + m_K} \left[ (p_B + p_K)_\mu q_\nu - q_\mu (p_B + p_K)_\nu \right].
\] (3)

Note that the finiteness of Eq.(1) at \( q^2 = 0 \) is guaranteed by assuming that \( f_+(0) = f_0(0) \).

The matrix elements \( \langle K(p_K) | \bar{s}\sigma_{\mu\nu}q^\nu b | B(p_B) \rangle \) and \( \langle K | \bar{s}b | B \rangle \) can be obtained from Eqs.(2) and (3) by multiplying both sides of these equations by \( q^\mu \) and using the equations of motion, we get:

\[
\langle K(p_K) | \bar{s}b | B(p_B) \rangle = f_0 \frac{m_B^2 - m_K^2}{m_b - m_s},
\] (4)

\[
\langle K(p_K) | \bar{s}\sigma_{\mu\nu}q^\nu b | B(p_B) \rangle = \frac{f_T}{m_B + m_K} \left[ (p_B + p_K)_\mu q^2 - q_\mu (m_B^2 - m_K^2) \right].
\] (5)

As we have already mentioned the form-factors entering Eqs.(2)-(5) represent the hadronization process, where in order to calculate these form-factors information about the nonperturbative region of QCD is required. Therefore for the estimation of the form-factors to be reliable a nonperturbative approach is needed. Among the nonperturbative approaches the QCD sum rule [13] is more predictive in studying the properties of hadrons. The form-factors appearing in the \( B \to K \) transition are computed in the framework of the three point QCD sum rules [14] and in the light cone QCD sum rules[15, 16]. We will use the result of the work in [16] where radiative corrections to the leading twist wave functions and \( SU(3) \) breaking effects are taken into account. As a result the form-factors are parameterized in the following way [16]:

\[
f_\ell(q^2) = \frac{r_1}{1 - q^2/m_\ell^2} + \frac{r_2}{(1 - q^2/m_\ell^2)^2},
\] (6)

where \( \ell = + \) or \( T \), and

\[
f_0(q^2) = \frac{r_2}{1 - q^2/m_0^2},
\] (7)

with \( m_1 = 5.41 \text{GeV} \) and the other parameters as given in Table 1.
Table 1: The parameters for the form-factors of the $B \to K$ transition as given in [16].

|     | $r_1$  | $r_2$  | $m^2_{f_{it}}$ |
|-----|--------|--------|----------------|
| $f_+$ | 0.162  | 0.173  | --             |
| $f_0$ | 0.     | 0.33   | 37.46          |
| $f_T$ | 0.161  | 0.198  | --             |

Using the definition of the form factors given in Eqs.(2)-(5) we arrive at the following matrix element for the $B \to K \ell^+\ell^-$ decay;

$$
\mathcal{M}(B \to K \ell^+\ell^-) = \frac{G_F \alpha}{4\sqrt{2}\pi} V_{tb} V_{ts}^* \left\{ \bar{\ell} \gamma^\mu \ell \left[ A(p_B + p_K)_{\mu} + Bq_{\mu} \right] \\
+ \bar{\ell} \gamma^\mu \gamma_5 \ell \left[ C(p_B + p_K)_{\mu} + Dq_{\mu} \right] + \bar{\ell} \ell Q + \bar{\ell} \gamma_5 \ell N \\
+ 4\bar{\ell} \sigma^{\mu\nu} \ell (-iG) \left[ (p_B + p_K)_{\mu} q_{\nu} - (p_B + p_K)_{\nu} q_{\mu} \right] \\
+ 4\bar{\ell} \sigma^{\alpha\beta} \ell \epsilon_{\mu\nu\alpha\beta} H \left[ (p_B + p_K)_{\mu} q_{\nu} - (p_B + p_K)_{\nu} q_{\mu} \right] \right\}. \tag{8}
$$

The functions entering Eq.(8) are defined as;

$$
A = (C_{LL} + C_{LR} + C_{RL} + C_{RR})f_+ + 2(C_{BR} + C_{SL}) \frac{f_T}{m_B + m_K},
$$
$$
B = (C_{LL} + C_{LR} + C_{RL} + C_{RR})f_+ - 2(C_{BR} + C_{SL}) \frac{f_T}{(m_B + m_K)q^2(m^2_B - m^2_K)},
$$
$$
C = (C_{LL} + C_{RR} - C_{LL}^* - C_{RL})f_+,
$$
$$
D = (C_{LR} + C_{RR} - C_{LL}^* - C_{RL})f_-,
$$
$$
Q = f_0 \frac{m^2_B - m^2_K}{m_b - m_s} (C_{LRR} + C_{LRL} + C_{LRL} + C_{RLR}),
$$
$$
N = f_0 \frac{m^2_B - m^2_K}{m_b - m_s} (C_{LRR} + C_{LRL} - C_{LRL} - C_{RLR}),
$$
$$
G = \frac{C_T}{m_B + m_K} f_T,
$$
$$
H = \frac{C_{TE}}{m_B + m_K} f_T, \tag{9}
$$

where

$$
f_- = (f_0 - f_+) \frac{m^2_B - m^2_K}{q^2}.
$$
From Eq.(8) it follows that the difference from the SM is due to the last four terms only, namely the scalar and tensor type interactions. For an analysis of the CP asymmetry it is necessary to compute the differential decay width for $B \rightarrow K\ell^+\ell^-$. From the expression of the matrix element given in Eq. (8) we calculate the following result for the dilepton invariant mass spectrum;
\[
\frac{d\Gamma(B \rightarrow K\ell^+\ell^-)}{ds} = \frac{G^2\alpha^2 m_B}{24\pi^5} |V_{ub}V_{ts}^*|^2 \lambda^{1/2}(1, \hat{r}_K, \hat{s})v\Delta(\hat{s}),
\]
where $\lambda(1, \hat{r}_K, \hat{s}) = 1 + \hat{r}_K^2 + \hat{s}^2 - 2\hat{r}_K - 2\hat{s} - 2\hat{r}_K\hat{s}$, $\hat{s} = q^2/m_B^2$, $\hat{r}_K = m^2_K/m_B^2$, $\hat{m}_\ell = m_\ell/m_B$, $v = \sqrt{1-4m^2_\ell/\hat{s}}$ is the final lepton velocity, and $\Delta(\hat{s})$ is;
\[
\Delta = \frac{4m_B^2}{3} \text{Re} \left[-96\lambda m_B^3 \hat{m}_\ell (AG^*) + 24m_B^2 \hat{m}_\ell^2 (1 - \hat{r}_K)(CD^*) + 12m_B \hat{m}_\ell (1 - \hat{r}_K)(CN^*)
\right.
\]
\[
+ 12m_B^2 \hat{m}_\ell^2 \hat{s} |D|^2 + 3\hat{s} |N|^2 + 12m_B \hat{m}_\ell \hat{s} (DN^*) + 256\lambda m_B^4 \hat{s} \hat{v}^2 |H|^2 + \lambda m_B^2 (3 - \hat{v}^2) |A|^2
\]
\[
+ 8s\hat{v}^2 |Q|^2 + 64\lambda m_B^4 \hat{s} (3 - 2\hat{v}^2) |G|^2 + m_B^2 \{2\lambda - (1 - \hat{v}^2)[2\lambda - 3(1 - \hat{r}_K)^2]\} |C|^2 \right].
\]

As we have already mentioned, our goal in this work is the study of possible CP violating asymmetries beyond the SM in the $B \rightarrow K\ell^+\ell^-$ decay; at this point we shall briefly remind the reader of the situation in the SM. In the SM the $C_9$ Wilson coefficient is the only one to have strong and weak phases. Strong phases arise from the short distance effects and resonances whereas the weak phase comes from the CKM elements. The remaining two coefficients, $C_7$ and $C_{10}$, are strictly real within the SM. From the parameterization of the form-factors it follows that they are inherently real and thus the imaginary parts in the functions in Eq.(11) can come only from the Wilson coefficients in Eq.(1). By strong and weak phases we mean the phases which are CP even and odd respectively. In other words we shall consider the picture where CP violating effects due to the short distance dynamics are parameterized by the Wilson coefficients. In principle all Wilson coefficients can have nonzero strong and weak phases.

In general the amplitude for $\bar{B} \rightarrow K$ has the general form [11];
\[
A(\bar{B} \rightarrow K) = e^{i\phi_1}A_1e^{i\delta_1} + e^{i\phi_2}A_2e^{i\delta_2},
\]
where the strong phases are labeled as $\delta$’s and the weak phases by $\phi$’s. As noted above the strong phases are CP even, whereas weak phases are odd under CP. Thus we arrive at an amplitude for the conjugated process, $B \rightarrow \bar{K}$, from Eq.(12);
\[
\bar{A}(B \rightarrow \bar{K}) = e^{-i\phi_1}A_1e^{i\delta_1} + e^{-i\phi_2}A_2e^{i\delta_2},
\]
where the amplitudes of the decay rate of particle and anti-particle can be defined by the CP asymmetry (in the decay rate) as;
\[
A_{CP} = \frac{|A|^2 - |\bar{A}|^2}{|A|^2 + |\bar{A}|^2} = \frac{-2A_1A_2\sin(\phi_1 - \phi_2)\sin(\delta_1 - \delta_2)}{A_1^2 + 2A_1A_2\cos(\phi_1 - \phi_2)\cos(\delta_1 - \delta_2) + A_2^2}.
\]
Note that from the above expression we observe that in order to have CP asymmetry we should have both strong and weak phases in the amplitude; where the strong phases are provided by $C_{\text{eff}}^9$. In the SM the weak phases for the $b \to s \ell^+\ell^-$ transition are negligible and hence the CP asymmetry for processes based on the quark level transitions, $b \to s \ell^+\ell^-$, are highly suppressed.

We will now consider the CP asymmetry in the decay width which is defined as;

$$A_{\text{CP}}(q^2) = \frac{d\Gamma(B \to K\ell^+\ell^-) - d\Gamma(B \to \bar{K}\ell^+\ell^-)}{d\Gamma(B \to K\ell^+\ell^-) + d\Gamma(B \to \bar{K}\ell^+\ell^-)}. \quad (15)$$

Note that one can also have a CP asymmetry from the Forward-Backward (FB) asymmetry[23]. However, in our present case the FB asymmetry for $B \to K\ell^+\ell^-$ vanishes within the SM.

We shall now consider the minimal extension of these Wilson coefficients. In this approach we shall assume that the Wilson coefficients corresponding to scalar and tensor type interactions vanish identically (of course in the general case we can consider all Wilson coefficients with an arbitrary weak phase). For scalar type operators which emerge in Supersymmetric (SUSY) models and two Higgs Doublet Models (2HDM) this assumption is justified when we have electrons or muons in the final state. The reason being that in SUSY and 2HDM these operators originate from an Higgs exchange which results in Wilson coefficients which are proportional to $m_\ell$, and hence negligible for $\ell = e, \mu$.

The Wilson coefficients for the dipole operator obeys;

$$C_{BR} = -2C_{\text{eff}}^7 m_b, \quad C_{SL} = -2C_{\text{eff}}^7 m_s, \quad (16)$$

with

$$C_{\text{eff}}^7 = |C_{\text{eff}}^7| \exp(i\phi_7),$$

where $\phi_7$ is an arbitrary phase and it is not constrained by the already observed branching ratio $Br(B \to K^*\gamma)$.

Regarding the appearance of the new weak phase in $C_{10}$ we feel that a few words are in order. One of the possible discrepancies between the experimental results[17] and the theoretical prediction for $B \to \pi K$ (from the $B \to \pi\pi$ data) can be resolved, as proposed in [18], by introducing a complex phase in the Wilson coefficient $C_{10} = C_{10}^{\text{SM}} \exp(i\phi_{10})$. In this prescription the weak phase given to $C_{10}$ does not effect the CP asymmetry in $B \to K\ell^+\ell^-$. 

We will assume that the Wilson coefficients $C_{RL}$ and $C_{RR}$ also have weak phases, that is;

$$C_{RL} = |C_{RL}| \exp(i\phi_{RL}),$$

$$C_{RR} = |C_{RR}| \exp(i\phi_{RR}). \quad (17)$$
The Wilson coefficient $C_9^{\text{eff}}(m_b, q^2)$ has a finite phase, where, in order to better appreciate this, we write its explicit phase content as:

$$
C_9^{\text{eff}}(m_b) = C_9(m_b) \left\{ 1 + \frac{\alpha_s(\mu)}{\pi} \omega(\hat{s}) \right\} + Y_{SD}(m_b, \hat{s}) + Y_{LD}(m_b, \hat{s}) \, ,
$$

(18)

where $C_9(m_b) = 4.334$. Here $\omega(\hat{s})$ represents the $\mathcal{O}(\alpha_s)$ corrections coming from the four quark operator $\mathcal{O}_9$ [19];

$$
\omega(\hat{s}) = -\frac{2}{9}\pi^2 - \frac{4}{3} Li_2(\hat{s}) - \frac{2}{3} \ln(\hat{s}) \ln(1 - \hat{s}) - \frac{5 + 4\hat{s}}{3(1 + 2\hat{s})} \ln(1 - \hat{s})
$$

$$
- \frac{2\hat{s}(1 + \hat{s})(1 - 2\hat{s})}{3(1 - \hat{s})^2(1 + 2\hat{s})} \ln(\hat{s}) + \frac{5 + 9\hat{s} - 6\hat{s}^2}{3(1 - \hat{s})(1 + 2\hat{s})} \, .
$$

(19)

In Eq.(18) $Y_{SD}$ and $Y_{LD}$ represent, respectively, the short and long distance contributions to the four quark operators $\mathcal{O}_{i=1,\ldots,6}$ [19,20]. Here $Y_{SD}$ can be obtained by a perturbative calculation;

$$
Y_{SD}(m_b, \hat{s}) = g(\hat{m}_c, \hat{s}) \left[ 3C_1 + C_2 + 3C_3 + C_4 + 3C_5 + C_6 \right]
$$

$$
- \frac{1}{2} g(1, \hat{s}) \left[ 4C_3 + 4C_4 + 3C_5 + C_6 \right]
$$

$$
- \frac{1}{2} g(0, \hat{s}) \left[ C_3 + 3C_4 \right] + \frac{2}{9} \left[ 3C_3 + C_4 + 3C_5 + C_6 \right]
$$

$$
- \frac{Y_{us}^*V_{ub}}{Y_{ts}^*V_{tb}} \left[ 3C_1 + C_2 \right] \left[ g(0, \hat{s}) - g(\hat{m}_c, \hat{s}) \right] \, ,
$$

(20)

where the loop function $g(m_q, s)$ represents the loops of quarks with mass $m_q$ at the dilepton invariant mass $s$. This function develops absorptive parts for dilepton energies $s = 4m_q^2$;

$$
g(\hat{m}_q, \hat{s}) = \frac{8}{9} \ln \hat{m}_q + \frac{8}{27} + \frac{4}{9} y_q - \frac{2}{9} (2 + y_q) \sqrt{|1 - y_q|}
$$

$$
\times \left\{ \Theta(1 - y_q) \left( \ln \frac{1 + \sqrt{1 - y_q}}{1 - \sqrt{1 - y_q}} - i\pi \right) + \Theta(y_q - 1) 2 \arctan \frac{1}{\sqrt{y_q - 1}} \right\},
$$

(21)

where $\hat{m}_q = m_q/m_b$ and $y_q = 4\hat{m}_q^2/\hat{s}$. Therefore, due to the extension of the absorptive parts of $g(\hat{m}_q, \hat{s})$ we see that the strong phases come from $Y_{SD}$. In particular one notices that the terms proportional to $g(0, \hat{s})$ have a non-vanishing imaginary part independent of the dilepton invariant mass.

In addition to these perturbative contributions the $\bar{c}c$ loops can excite low-lying charmonium states $\psi(1s), \cdots , \psi(6s)$ whose contributions are represented by $Y_{LD}$ [21];

$$
Y_{LD}(m_b, \hat{s}) = \frac{3}{\alpha_s} \left\{ - \frac{Y_{us}^*V_{ub}}{Y_{ts}^*V_{tb}} C^{(0)} - \frac{Y_{us}^*V_{ub}}{Y_{ts}^*V_{tb}} \left[ 3C_3 + C_4 + 3C_5 + C_6 \right] \right\}
$$

$$
\times \sum_{V_i=\psi(1s),\cdots,\psi(6s)} \frac{\pi K_i \Gamma(V_i\rightarrow\ell^+\ell^-) M_{V_i}}{M_{V_i}^2 - \hat{s}m_b^2 - iM_{V_i}\Gamma_{V_i}} \, ,
$$

(22)
where $\kappa_i$ is a phenomenological parameter taken here to be 2.3 so as to produce the correct branching ratio of $Br(B \to J/\psi K^* \to K^* \ell\ell) = Br(B \to J/\psi K^*) Br(J/\psi \to \ell\ell)$ [5], and $C^{(0)} \equiv 3C_1 + C_2 + 3C_3 + C_4 + 3C_5 + C_6 = 0.362$. Contrary to $Y_{SD}$ the long-distance contribution in $Y_{LD}$ has both weak and strong phases. The weak phases follow from the CKM elements whereas the strong phases come from the $\hat{s}_i$ values for which the $i$-th charmonium states are on shell. Therefore, the Wilson coefficient $C_9^{eff}(m_b)$ has both weak and strong phases already in the SM.

In this sense the Wilson coefficients $C_7^{eff}(m_b)$ and $C_{10}(m_b)$ can not develop any strong phase, and thus, $\phi_7$ and $\phi_{10}$ should necessarily originate from physics beyond the SM. As such the phases of $\phi_7$ and $\phi_{10}$ can be chosen to have a purely weak character.

3 Numerical analysis

In this section we present our numerical results for the asymmetries $A_{CP}$ for the $B \to K \mu^+\mu^-$ decay. Note that the parameters for the hadronic form-factors are taken from Table I. For values of the Wilson coefficients in the SM we have used $C_3 = 0.011$, $C_4 = -0.026$, $C_5 = 0.007$, $C_6 = -0.031$, $C_7^{eff} = -0.313$, $C_9 = 4.344$, and $C_{10} = -4.664$. For further numerical analysis the values of the new Wilson coefficients are needed, where we have varied them in the range $-|C_{10}| < C_X < |C_{10}|$.

The experimental value of the branching ratio of the $B \to K(K^*)\ell^+\ell^-$ decays[8,9] and the bound on $Br(B \to \mu^+\mu^-)$[22] suggest that this is the right order of magnitude. It should be noted that the experimental results lead to strong restrictions on some of the Wilson coefficients, namely $-2 \leq C_{LL}$ and $C_{RL} \leq 2.3$, while the remaining coefficients vary in the range $-|C_{10}| < C_X < |C_{10}|$.

For the remaining parameters we take $m_b = 4.8$GeV, $m_c = 1.35$GeV, $m_B = 5.28$GeV and $m_K = 0.496$GeV.

For the kinematical interval the dilepton invariant mass is $4m_\ell^2 \leq q^2 \leq (m_B - m_K)^2$ where the $J/\psi$ family of resonances can be excited. The dominant contribution comes from the three low-lying resonances $J/\psi, \psi', \psi''$ in the interval $8$GeV$^2 \leq q^2 \leq 14.5$GeV$^2$. In order to minimize the hadronic uncertainties we will discard this subinterval in the analysis below by dividing the $q^2$ region into low and high dilepton mass intervals;

$$\begin{align*}
\text{Region I} & : \quad 4m_\ell^2 \leq q^2 \leq 8 \text{GeV}^2, \\
\text{Region II} & : \quad 14.5 \text{GeV}^2 \leq q^2 \leq (m_B - m_K)^2,
\end{align*}$$

(23)

where the contribution of the higher resonances do still exist in the second region.

As mentioned previously, we have analyzed the case where there are four weak phases: $\phi_7, \phi_{10}, \phi_{RL}$ and $\phi_{RR}$.

In fig. 1 we have presented $A_{CP}$ in the $\phi_7-q^2$ plane for the $B \to K \mu^+\mu^-$ decay for Region I and Region II respectively. In Region I the CP asymmetry is practically independent of $q^2$, becoming
maximal in the value for CP violation at $\phi_7 = \pi/2$. In Region II, however, the $q^2$ dependence is comparatively enhanced as the dominance of the dipole coefficient is now reduced. Aside from this our figures suggest that the CP asymmetry in Region II is four times larger than in Region I, and this confirms our earlier expectation.

Since the CP asymmetry is dependent on $q^2$ and the new weak phases there can appear some difficulties. The dependence of one of the variables, for example $q^2$, can be removed by integrating over $q^2$ in the allowed practical kinematical region, where the averaged asymmetries could be measured more easily experimentally. Therefore we shall now discuss only averaged CP asymmetries, which we define in the following way. That is, our averaging procedure is defined by:

$$\langle A_{CP} \rangle = \frac{\int_{R_i} A_{CP} \frac{d\Gamma}{dq^2} dq^2}{\int_{R_i} \frac{d\Gamma}{dq^2} dq^2}. \quad (24)$$

where $R_i$ means Region I or II.

We now depict in fig. 2 the $\phi_7$ dependence of the averaged asymmetries $\langle A_{CP} \rangle$. From this figure it can be observed that the average $\langle CP \rangle$ asymmetry can attain values of 3%. Differences from zero of any value of $\langle A_{CP} \rangle$ would be an unambiguous indication of the existence physics beyond the SM.

In fig. 3 we have plotted the dependence of CP asymmetry on the dilepton invariant mass and $\phi_{RL}$. In fig. 5 we have shown the same kind of plot but for $\phi_{RR}$. We have also shown the correlation of averaged CP asymmetry and the integrated branching ratios. In fig. 4 the variation of $\langle A_{CP} \rangle$ with integrated branching ratio for $B \to K\mu^+\mu^-$ for $C_{RL}$ is shown. In this figure we have
used three different values of $C_{RL}$ and have varied the phase ($\phi_{RL}$) in the range $0 \leq \phi_{RL} \leq 2\pi$. All the other Wilsons are taken to have their SM values. In a similar graph, given in fig. 6, we have varied $C_{RR}$.

In the present work we have studied the sensitivity of the CP violating asymmetry on the new weak phases appearing in the Wilson coefficients. We have also observed that the CP asymmetry in Region II is 4-5 times larger than that observed in Region I when we consider a weak phase $\phi_7$. This can be understood in that in Region II contributions coming from other operators become comparable with the dipole operator $O_7$, where this operator is dominant in Region I. Having obtained the averaged $\langle A_{CP} \rangle$ asymmetry we obtained a maximal value of approximately 3%. Note that an additional weak phase in $C_{10}$ will not give rise to any CP asymmetry, however, if non-standard\footnote{by non-standard we mean operators which are not present within the SM} electroweak operators are considered then the CP asymmetry in the region of high dilepton invariant mass can reach a value of up to 10%.

As stated earlier, we can also, in principle, have weak phases in scalar and pseudo-scalar operators. The presence of weak phases in these operators can also substantially effect the CP asymmetry. The popular extensions of the SM, such as SUSY and 2HDM, all predict the existence of such operators. However, the magnitude of these Wilson coefficients is predicted to be small when the lepton $\ell = e$ or $\mu$. In the presence of these operators one also gets a non-zero value for the FB asymmetry in $B \rightarrow K\ell^+\ell^-$. The FB asymmetry could provide another measure of CP asymmetry\cite{23} which has not been considered in this work.

The observation of CP asymmetry in $B \rightarrow K\ell^+\ell^-$ would not only tell us about the nature of weak phases but would also give us an insight into the structure of the effective Hamiltonian.
Figure 3: A plot of the CP asymmetry in $B \rightarrow K\mu^+\mu^-$ as a function of the phase $\phi_{RL}$ and the dilepton invariant mass. In this plot we have taken $|C_{RL}| = 2$ and with the other Wilsons as having their SM values.

Therefore the measurement of the CP violating asymmetry would provide us with an useful insight into the mechanism of CP violation, which in turn would serve as a good test for physics beyond the SM.
