Classification of contraction algebras and pre-Lie algebras associated to braces and trusses

Natalia Iyudu

Dedicated to the memory of Ernest Borisovich Vinberg

Abstract

We develop tools for classification of contraction algebras and apply these to solve the problem on classification up to isomorphism of 8 and 9 dimensional algebras corresponding to 3-fold flops. We prove that there is only one up to isomorphism contraction algebra of dimension 8, and two algebras of dimension 9. The formulae for the dimension of algebra, depending on the type of the potential are obtained.

In the second part of the paper we show that associated graded structure to brace and truss with appropriate descending ideal filtration is pre-Lie.

MSC: 16A22, 16S37, 14A22

1 Introduction

We consider here first classification of 8 and 9 dimensional two generated contraction algebras. Contraction algebras were introduced in Donovan-Wemyss work on minimal model program and noncommutative resolution of singularities \cite{27,9}. Namely, they serve as noncommutative invariants attached to a birational flopping contraction: \( f : X \rightarrow Y \) which contracts rational curve \( C \approx \text{Pr}^1 \subset X \) to a point, where \( X \) is a smooth quasi-projective 3-fold. It is a new, essentially noncommutative invariant of curve contraction, which is not a number, as ones previously known, such as Gopakumar-Vafa invariants, but instead an associative noncommutative algebra. It recovers all known invariants in a natural way, and as it is argued in \cite{4}, the contraction algebras are finer invariants of 3-fold flops, than various curve-counting theories, as there are examples where curve-counting invariants are the same, but contraction algebras are not isomorphic. We will see these examples here within the classification of 9 dimensional contraction algebras. In \cite{4}, the question on this classification was raised and it was noted that ‘the isomorphism problem is delicate and is in general also difficult’. Thus we develop here techniques
which can serve to solve this problem of classification up to isomorphism. Application of this technique allows us to classify all 8 and 9 dimensional contraction algebras on 2 generators (corresponding to 3-fold flops). We hope that these classification results can help to better understand the ways contraction algebras capture geometric information. In particular, where the refinements, for example in shape of derived contraction algebras are needed.

It is known due to result of Van den Bergh that contraction algebras are potential, that is defining relations are noncommutative partial derivatives of a potential. In view of the conjecture of Wemyss and Donovan, (see also for evidences for the conjecture), saying that any potential algebra (of rose quiver, and more generally of a quiver from a certain wider list) can be realised as a contraction algebra, we approach the study of contraction algebras via the study of potential algebras by methods similar to the ones from for example.

In we answered question due to M.Wemyss on the minimal dimension for a contraction algebra in two generators, and also found a conditions on the potential necessary to produce a finite dimensional algebra (or an algebra of linear growth). It turned out that the minimal dimension possible for a contraction algebra is 8, and the potential should be nonhomogeneous and contain terms of degree 3, in order algebra to be finite dimensional or of linear growth.

Here we prove the following classification results.

**Theorem 1.** There is one up to isomorphism contraction algebra $A = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(P)$ of dimension 8, and it is defined by the potential $x^3 + y^3 + xyxy$. There are two up to isomorphism contraction algebras $A = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(P)$ of dimension 9, and they are defined by potentials $x^2y + y^4$ and $x^2y + y^4 + y^5$.

We start the proof by showing that invertible linear changes of variables can bring a cubic potential to one of the three forms: with the cubic part $x^2y$, or $x^3$ or $x^3 + y^3$. We show that 8-dimensional algebras can appear only from the potential with cubic term $x^2y$, and 9-dimensional algebras only from the potential with cubic term $x^3 + y^3$. We also found the formulae for the dimension of the contraction algebra. In case of the potential with cubic term $x^2y$ combination of Lemma 21, Proposition 22 and Corollary 23 provides the following dimension counting result.

**Theorem 2.** Let $A = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(F)$, be a finite dimensional algebra with the potential $F = x^2y + F_4 + \ldots + F_r$, then an invertible changes of variables can bring the potential $F$ to $x^2y + y^4p(y)$, and the dimension of $A$ is: $\dim A = 3(2n+3)$, if $k = 2n$, $\dim A = 4n+k+9$, if $k < 2n$, ($k$ is odd). Here $k$ is degree of polynomial $p(y)$, and $2n$ is degree of its even part.

The second part of the paper is dedicated to the connections between pre-Lie algebra structures with braces and trusses. There were noticed a numerous connections between braces and pre-Lie algebras inspired by the connections between Lie algebras and groups. We focus here on the fact that whenever the brace is endowed
with decreasing ideal filtration with zero intersection, the associated graded structure is a pre-Lie algebra.

Pre-Lie structures are prominent by their numerous appearances in different areas. They were introduced by Vinberg under the name left-symmetric algebras (LSA) in his study of convex homogeneous cones [24], and a graded version of pre-Lie algebras appeared at the same time in the work of Gerstenhaber [17] as a structure on the Hochschild complex of an associative algebra. In fact this structure is present in rooted trees with drafting operation and can be traced back to the work of A.Cayley [7].

**Definition.** A set \((A, *, +)\) with two binary operations is called a brace, if \((A, +)\) is an abelian group, \((A, \circ)\) is a group and the following mix of associativity and distributivity axioms holds:

\[(a * b + a + b) * c = a * c + b * c + a * (b * c).\]

Here we denote \(a \circ b = a + b + a * b\).

We consider also the notion of truss, which generalise braces. It was introduced by T.Brzeziński [6] to incorporate the notion of associative ring and the brace.

**Definition 4.** A set \((A, \circ, +)\) with two binary operations is called a truss, if \((A, +)\) is an abelian group, \((A, \circ)\) is a semigroup and

\[a \circ (b + c) + a = a \circ b + a \circ c + \alpha(a)\]

where \(\alpha\) is some function \(\alpha : A \rightarrow A\).

In this second part of the paper we prove the following.

**Theorem 5.** Let \(A\) be an \(\mathbb{K}\)-brace, endowed with a descending ideal filtration with zero intersection, then the associated graded structure of a brace \(A\) is a pre-Lie algebra over \(F\).

We notice also that the result of lemma 15 [23] extends from the nilpotent case to the case of arbitrary descending ideal filtration with zero intersection, and spell out the right distributivity formula, which holds in a completion \(\hat{A}\) of \(A\) in the topology defined by the filtration (see Lemma 30 in Section 6).

It turns out that the analogous results to Theorem 6 holds for trusses under a mild condition on filtration (Corollary 34, Section 7).

**Corollary 6.** Let \(B\) be a truss endowed with descending filtration \(B = \bigcup B_i\) where \(B_i \triangleleft B\), \(B_{i+1} \subset B_i, B_i \circ B_j \subset B_{i+j}\), satisfying \(\bigcap_{i=1}^{\infty} B_i = 0\), and such that \(\deg \alpha(a) > 2\). Then the associated graded structure \(B_{gr} = \oplus B_i / B_{i+1} = \oplus \hat{B}_i\) is a pre-Lie algebra.
2 Asknowledgements

I would like to thank Michael Wemyss for enlightening conversations and for asking very interesting questions on contraction algebras, I am also very thankful to Agata Smok-
tunowicz for introducing me to braces and communicating a series of inspiring questions. I am grateful to MPIM and IHES for support and excellent research atmosphere.

3 Preliminary facts

Let $\mathbb{K}(x, y)$ be a free noncommutative algebra on free generators $x, y$, and $\mathbb{K}[[x, y]]$ be a free algebra of formal power series on $x, y$. Let $A$ be the quotient of the formal power series in two variables by an ideal generated by relations $R$: $A = \mathbb{K}[[x, y]]/id_{\mathbb{K}[[x, y]]}(R)$, and $B = \mathbb{K}(x, y)/(R)$, be the quotient of the free associative algebra by the ideal generated by the same relations, but in $\mathbb{K}(x, y)$.

Let us remind the notion of completion of an algebra $B$. We assign to variables $x$ and $y$ degree 1, and say that polynomial $p \in \mathbb{K}(x, y)$ (a series $p \in \mathbb{K}[[x, y]]$) have a degree $n$, if the minimal degree of monomial on $x, y$, present in $p$ (with nonzero coefficient) is $n$. We will use this definition of degree throughout the paper.

Definition 7. We say that the ideal $\overline{I}$ is the completion of the ideal $I \triangleleft \mathbb{K}(x, y)$ if $\overline{I} = \bigcap_{n=1}^{\infty} I^{[n]}$, where $I^{[n]} = I + id$ (monomials of deg $(n + 1)$). Obviously, $I^{[n+1]} \subseteq I^{[n]}$, and $I \subset \overline{I}$. The algebra $\overline{A} = \mathbb{K}(x, y)/\overline{I}$ is then called a completion algebra of $A = \mathbb{K}(x, y)/I$.

Note, that the completion algebra $\overline{A}$ is a quotient of algebra $A$ itself.

It is easy to see from this definition that $\mathbb{K}[[x, y]]/id_{\mathbb{K}[[x, y]]}(R) = \mathbb{K}(x, y)/id_{\mathbb{K}(x, y)}(R)$.

We will mention in this section few more facts on this construction, which we use freely throughout the text.

Now let us give two equivalent definition of an algebra given by a potential.

Definition 8. Let $F$ be a cyclic polynomial $F \in \mathbb{K}(x, y)/[\mathbb{K}(x, y), \mathbb{K}(x, y)]$, the potential algebra $A(F)$, is the factor of $\mathbb{K}(x, y)$ by the ideal $I_F$ generated by $\frac{\partial F}{\partial x}$ and $\frac{\partial F}{\partial y}$, where the linear maps $\frac{\partial}{\partial x}, \frac{\partial}{\partial y} : \mathbb{K}(x, y) \rightarrow \mathbb{K}(x, y)$ are defined on monomials as follows:

$$\frac{\partial w}{\partial x} = \begin{cases} u & \text{if } w = xu, \\ 0 & \text{otherwise,} \end{cases} \quad \frac{\partial w}{\partial y} = \begin{cases} u & \text{if } w = yu, \\ 0 & \text{otherwise.} \end{cases}$$

Definition 9. (Ginzburg) Associated to any (not necessary cyclic) polynomial $\Phi \in \mathbb{K}(x, y)$ the potential algebra is the factor of $\mathbb{K}(x, y)$ by the ideal $I_\Phi$ generated by $\frac{\partial \Phi}{\partial x}$ and $\frac{\partial \Phi}{\partial y}$, where the linear maps $\frac{\partial}{\partial x}, \frac{\partial}{\partial y} : \mathbb{K}(x, y) \rightarrow \mathbb{K}(x, y)$ are defined on monomials as follows. Given a monomial $u = z_1 z_2 \ldots z_r$, $z_i = x$ or $y$, define $\frac{\partial u}{\partial z_j} = \sum_{s \mid s \neq j} z_{i_1} z_{i_2} \ldots z_{i_s} z_{i_{s+1}} \ldots z_{i_r}$, then extend this definition by linearity.
The difference between these two definitions is that the first one works only for cyclic polynomials, and the second can be defined for any polynomials. However the class of potential algebras they both produce is the same.

Note also one simple fact about the syzygy, which holds for any algebra given by a cyclic potential.

**Lemma 10.** For every $F \in \mathbb{K}(x,y)$ such that $F_0 = 0$, $F = x\frac{\partial F}{\partial x} + y\frac{\partial F}{\partial y}$. Furthermore, the equality $F = \frac{\partial F}{\partial x} x + \frac{\partial F}{\partial y} y$ holds if and only if $F$ is cyclicly invariant. In particular, $[x, \frac{\partial F}{\partial x}] + [y, \frac{\partial F}{\partial y}] = 0$ if and only if $F$ is cyclicly invariant.

**Proof.** Trivial.

**Proposition 11.** Let $A = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}_{\mathbb{K}\langle\langle x, y \rangle\rangle}(F)$ where $F$ is not necessarily homogeneous polynomial, is a finite dimensional algebra. Then $A$ is nilpotent.

**Proof.** Since $A$ is finite dimensional, if we take enough powers of $a$, they will be linearly dependant, so $a$ is algebraic: $p(a) = a_0 + a_1 a + a_2 a^2 + ... + a_n a^n = 0$. Note that if $a_0$ would be nonzero, then the polynomial is invertible in $\mathbb{K}\langle\langle x, y \rangle\rangle$ and it can not be equal to zero. Let us take the maximal power of $a$ such that $p(a) = a^k (1 + a_1' a + a_2' a^2 + ...)$ since the second multiple is invertible in $\mathbb{K}\langle\langle x, y \rangle\rangle$, we have $a^k = 0$. Thus $A$ is nil, and being finite dimensional it is nilpotent.

**Proposition 12.** The change of variables (not necessary linear) in the potential coincide with the same change of variables in the relations.

**Proof.** The proof is based on the following lemma.

**Lemma 13.** The formula for the derivative of the composition works, and easy to check in the Ginzburg definition of the potential algebra. Let $G = F(u(x,y), v(x,y))$, where $u(x,y), v(x,y)$ are monomials, then

$$
\frac{\partial G}{\partial x} = \partial_1 F(u(x,y), v(x,y)) \cdot \frac{\partial u(x,y)}{\partial x} + \partial_2 F(u(x,y), v(x,y)) \cdot \frac{\partial v(x,y)}{\partial x}
$$

$$
\frac{\partial G}{\partial y} = \partial_1 F(u(x,y), v(x,y)) \cdot \frac{\partial u(x,y)}{\partial y} + \partial_2 F(u(x,y), v(x,y)) \cdot \frac{\partial v(x,y)}{\partial y}.
$$

Here $\cdot$ stands for 'noncommutative multiplication' of monomials.

**Proof.** Easy check.
Since $1 + m(x, y)$ is invertible in $\mathbb{K}\langle\langle x, y \rangle\rangle$, we see that ideals generated by $\frac{\partial G}{\partial x}, \frac{\partial G}{\partial y}$ and $\frac{\partial F}{\partial x}(x + m(x, y), y), \frac{\partial F}{\partial y}(x + m(x, y), y)$ do coincide.

**Proposition 14.** Let $A = \mathbb{K}\langle\langle x, y \rangle\rangle / \text{id}_{\mathbb{K}\langle\langle x, y \rangle\rangle}(\partial_x F, \partial_y F)$. If this algebra is nilpotent, then the change of variables of the form $x \to x + f(x, y); y \to y$, where $f(x, y)$ is a polynomial on $x, y$ of degree two or bigger, is invertible.

**Proof.** The change of variables is given by triangular matrix with 1th on the diagonal, and this matrix is finite due to nilpotency condition.

**Proposition 15.** Let $A = \mathbb{K}\langle\langle x, y \rangle\rangle / \text{id}_{\mathbb{K}\langle\langle x, y \rangle\rangle}(R)$, and $B = \mathbb{K}(x, y)/(R)$. If $A$ is finite dimensional and nilpotent, then $A$ is a Jacobson radical of $B$: $A = \text{Jac}(B)$

Another essential tool we will use here is the Gröbner bases theory, so we recall some basic terminology here. For more detailed account see, for example, [20]

Suppose in $\mathbb{K}\langle\langle Y \rangle\rangle$ we have fixed some well-ordering (that is, ordering compatible with multiplication), for example, (left-to-right) degree-lexicographical ordering: we fix an order on variables, say $y_1 < ... < y_n$, and compare monomials on $Y$ of the same degree lexicographically (from left to right). Then we say, that monomials of higher (or lower) degree are bigger in the ordering. Polynomials are compared by their highest terms in this ordering. This order should have d.c.c.

**Definition 16.** Monomials $u, v \in \mathbb{K}\langle\langle Y \rangle\rangle$ form an ambiguity $(u, v)$, if for some $w \in \mathbb{K}\langle\langle Y \rangle\rangle$, $uw = wv$.

**Definition 17.** Let $u, v$ be two monomials $u, v$, which are highest terms of the elements $U, V$ from the ideal $I \in \mathbb{K}\langle\langle Y \rangle\rangle : U = u + \tilde{u}, V = v + \tilde{v}$, where $\tilde{u}, \tilde{v} \in \mathbb{K}\langle\langle Y \rangle\rangle$, smaller than $u, v \in \langle\langle Y \rangle\rangle$ respectively: $\tilde{u} < u, \tilde{v} < v$. Then the resolution of the ambiguity $(u, v)$ formed by monomials $u, v$ is a polynomial $Uw - wV = \tilde{u}w - w\tilde{v}$, which is reducible to zero modulo generators of an ideal.

**Definition 18.** A reduction on $\mathbb{K}\langle\langle Y \rangle\rangle$ modulo generators of an ideal $f_i = \bar{f}_i + \tilde{f}_i$, where $\bar{f}_i$ is a highest term of $f_i$, is a collection of linear maps defined on monomials as follows: $r_{u, f_i, \bar{f}_i}(w) = u\bar{f}_i \tilde{v}$, if $w = u\bar{f}_i \tilde{v}$, and $w$ otherwise.

The polynomial is called reducible to zero if there exists a sequence of reductions modulo generators of an ideal, which results in zero.

In our arguments we often follow the Buchberger algorithm for construction of non-commutative Gröbner basis.

### 4 Classification of 8-dimensional contraction algebras

Let $A$ be a potential completion algebra
for some potential $F \in \mathbb{K}(x, y)$.

We are interested in the case, when potential algebra is finite dimensional. As we have proved in [16, 15] it is only possible if the potential is nonhomogeneous and has terms of degree 3. General term of degree three is $F_3 = a_1 x^3 + a_2 x^2 y \circ + a_3 x y^2 \circ + a_4 y^3$. Let us start with the

**Lemma 19.** By a non-degenerate linear transformation a general potential $F = F_3 + f_4 + \ldots + F_r, F_3 = a_1 x^3 + a_2 x^2 y \circ + a_3 x y^2 \circ + a_4 y^3$ can be made into one of the four potentials: $F = 0 + F_4 + \ldots + F_r, F = x^3 + F_4 + \ldots + F_r, F = x^2 y \circ + F_4 + \ldots + F_r, or F = x^3 + y^3 + F_4 + \ldots + F_r$.

**Proof.** Indeed, consider the abelianisation of $F_3$: $F_3^{ab} = a_1 x^3 + 3a_2 x^2 y + 3a_3 x y^2 + a_4 y^3$. It can be decomposed as $F_3^{ab} = u_1(x, y)u_2(x, y)u_3(x, y)$ with $\deg u_i = 1$. If $F_3^{ab} \neq 0$, there are three possibilities: all lines $u_1, u_2, u_3$ are parallel: $u_1 = \alpha u, u_2 = \beta u, u_3 = \gamma u, u = ax + by, (a, b) \neq (0, 0)$, then there is a change of variables making the $F_3$ into $x^3$. Another possibility is that two of $u_1$ and $u_2$ are parallel, and they are not parallel to $u_3$, then $F$ can be made into $x^2 y \circ$. If all three $u_1, u_2, u_3$ are pairwise nonparallel, then the linear transformation $x \to x', y \to y'$, where $u_1 = x' + y', u_2 = x' + \theta y', \theta^2 = 1$ will bring $u_1u_2u_3 = (x + y)(x + \theta y)(x + \theta^2 y)$ to $x^3 + y^3$.

Thus, we will use the fact that up to isomorphism a nonzero degree 3 homogeneous cyclic potential can be only either $x^3$ or $x^3 + y^3$ or $x y^2 \circ = x y^2 + y^2 x + x y$.

### 4.1 Potential with cubic term $x^2 y \circ$

We will show first that in the cases of potential with $F_3 = x^2 y \circ$ and $F_3 = x^3$ the dimension of algebra is bigger or equal than 9. Then main our consideration for the dimension 8 will go to the case of potential with $F_3 = x^3 + y^3$.

**Lemma 20.** Let $A = \mathbb{K}[[x, y]]/\langle \partial_x F, \partial_y F \rangle$ for the potential $F \in \mathbb{K}(x, y), F = x^2 y \circ + F_4 + \ldots + F_r$. Then $\dim A \geq 9$.

**Proof.** Denote components of the filtration on $A$ by $A_n$: $A = \bigoplus_{n=0}^{\infty} A_n$. Here $A_n$ stands for polynomials (series) with the (lower) degree $n, A_0 = \mathbb{K}$. We can consider associated graded algebra $A_{gr} = \bigoplus_{n=0}^{\infty} A_n/A_{n+1}$ where the $n$th graded component consists of series starting in degree exactly $n$. The dimensions of $A_{gr}$ and $A$ do coincide and are equal to $\sum_{n=0}^{\infty} (A_n/A_{n+1})$. Obviously $A_1/A_2 = \text{span}(x, y)\mathbb{K}$, since the potential is of degree 3 and there are no relations on monomials of degree smaller than two. The relations in degree two are $\partial_x F_3 = x^2 + \ldots$ and $\partial_y F_3 = y x + x y + \ldots$. Thus, modulo this ideal any occurrence of $x^2$ can be reduced to sum of monomials of higher degree, and $y x$ can be changed to $-y x$ plus sum of monomials of higher degree.
This means that the linear basis in $A_2/A_3$ consists of $x^2, yx$, so $\deg A_2/A_3 = 2$

Let us call $n$-normal monomials those monomials of degree $n$, which does not contain as submonomials elements of linear basis of $A_{n-1}/A_n$.

Consider now 3-normal monomials, that is those monomials of degree 3, which contain as a submonomials only already reduced monomials of degree 2: $x^2$ and $xy$. There are two of them: $x^3$ and $yx^2$. Thus the dimension of $A_3/A_4$ can be 2 or smaller, if there are relations on these monomials coming from the ideal generated by the potential. But in this case there are no such relations, because the relations on the level of degree 2, that is relations $y^2 = 0, xy = -yx$ with the ordering $x > y$ form a Gröbner basis. Thus $\dim A_3/A_4 = 2$.

Consider now $A_4/A_5$, 4-normal monomials are $x^4, yx^3$. Look how we can get dependances between them out of relations. We would multiply $\partial_x F$ and $\partial_y F$ from the right and from the left by a linear expressions on $x, y$, or from one side by a quadratic expression. We can not get new relations on monomials of degree 4 this way, again because quadratic parts of $\partial_x F$ and $\partial_y F$ form a Gröbner basis. However we can get new relations in terms of degree 4 if we multiply $\partial_x F$ and $\partial_y F$ by linear terms from the right or from the left, and terms of degree 3 cancel. Then the relation we get will be of degree 4, so it might create dependance between $x^4$ and $yx^3$. We want to find out how many of such constrains we can get, to know the dimension of $A_4/A_5$. For that we consider two possible ambiguities: $x^3 = x^2 \cdot x = x \cdot x^2$ and $x^2 y = x \cdot xy = x^2 \cdot y$ between $\partial_x F_3 = xy + yx$ and $\partial_y F_3 = x^2$. The resolution of these two ambiguities leads to two elements, generating the space $\Omega$ of monomials with zero third component, spanned by $u_1 \cdot \partial_x F_3, \partial_x F_3 \cdot u_2, v_1 \cdot \partial_y F_3, \partial_y F_3 \cdot v_2$, with $u_i, v_i$ - linear polynomials.

In this case resolution of ambiguity $x^2 y$ will give the relation $[\partial_x F, x] + [\partial_y F, y]$, which as we know already present in $\Omega$, as it is a syzygy between the relations $\{1\}$. Thus only the ambiguity $x^3$ can bring new relation. In other words, two relations we got from the ambiguities are linearly dependant. Thus the space $\Omega$ is at most one dimensional and $\dim A_4/A_5$ can be only one or two.

If it is two, then the overall dimension of $A$ we got already is $\sum_{i=0}^{4} \dim A_{i}/A_{i+1} = 1 + 2 + 2 + 2 + 2 = 9$.

If it is one, then we will look at dimension of $A_5/A_6$. It is shown by brute force calculation, that it is at least one. Then the overall dimension we got up to this step is $\dim A = \sum_{i=0}^{5} \dim A_{i}/A_{i+1} = 1 + 2 + 2 + 2 + 1 + 1 = 9$. $\square$

Let us now formulate a more general fact, which in particular will show that the dimension in this case is $\geq 9$, but also will be used later in classification of degree 9.

First let us note the following

**Lemma 21.** Let $A = \mathbb{K}[\langle x, y \rangle]/id(F)$, where the potential $F = x^2 y^2 + F_3 + \ldots + F_r$, then by composition of invertible changes of variables of the form $x \to x, y \to y + f(x, y)$, or $y \to y, x \to x + g(x, y)$ where $f(x, y), g(x, y)$ are polynomials of degree $\geq 2$, we can bring the potential to the shape $F = x^2 y^2 + y^4 p(y)$, for a polynomial $p(y)$.
Proof. Let us list the changes of variables and the corresponding terms of the potential, which could be killed by them:

\[ y \to y + cx^2 - - - x^4, y \to y + cxy - - - x^3y \bigcirc, y \to y + cy^2 - - - x^2y^2 \bigcirc. \]
\[ x \to x + cy^2 - - - xy^3 \bigcirc, x \to x + cxy - - - xyxy \bigcirc, y \to y + cy^2 - - - x^2y^2 \bigcirc. \]

Only monomial \( y^4 \) will remain in the potential in degree 4.

\[ y \to y + cx^3 - - - x^5, y \to y + cx^2y - - - x^4y \bigcirc, y \to y + cxy^2 - - - x^3y^2 \bigcirc, \]
\[ y \to y + cxyy - - - x^2yxy \bigcirc, y \to y + cy^3 - - - x^2y^3 \bigcirc, \]
\[ x \to x + cyx^2 - - - x^2yxy \bigcirc, x \to x + cxyy - - - xyxy^2 \bigcirc, y \to y + cy^3 - - - xy^4 \bigcirc. \]

Only monomial \( y^5 \) will remain in the potential in degree 5, etc.

Thus, after composition of such changes of variables we get a potential \( F = x^2y \bigcirc + y^4p(y) \), for some polynomial \( p(y) \).

\[ \square \]

**Proposition 22.** Let \( A = \mathbb{K}[[x,y]]/id(F) \), where the potential \( F = x^2y \bigcirc + p(y) \), \( p(y) \) is the polynomial of degree \( k \), with even part of degree \( 2n \). Then the linear basis of \( A \) consists of monomials \( y^n, xy^{n-1} \) for \( n = 0, \ldots, 2n + 3 \), and \( y^N \) for \( N = 2n + 4, \ldots, 2n + k + 5 \).

**Proof.** Let us construct a Gröbner bases on two relations we have from the potential:

\[ \partial F : x^2 = y^3p(y), \partial_y F : xy = -yx. \]

The ambiguity \( x^2y \) is resolvable. Indeed, \( x^2y \to y^3p(y)y + xyx \neq yx^2 \neq y^4p(y) = 0 \).

The ambiguity \( x^3 \) reduces to \( xy^3p(y) - y^3p(y)x = -2y^3p_{\text{even}}(y)x = 0 \), where \( p_{\text{even}}(y) \) stands for the even part of the polynomial \( p(y) \), since due to the relation \( xy = -yx \), \( xy^n = y^n x \), if \( n \) is even, and \( xy^n = -y^n x \), if \( n \) is odd. Thus from the above we got new relation

\[ y^3p_{\text{even}}(y)x = 0. \]

There are no other ambiguities between old relations. Note that in particular this implies that if \( p(y) \) is odd, then the algebra is infinite dimensional.

Denote

\[ p_{\text{even}}(y) = cy^{2n} + \ldots, n = 0, 1, \ldots, c \neq 0, \]

then we can rewrite the latter relation \( y^3p_{\text{even}}(y)x = 0 \) as \( cy^3y^{2n}(1 + u(y))x = 0 \). Since \( 1 + u(y) \) is invertible and (anti-)commute with \( x \), we have the new relation

\[ y^{2n+3} = 0. \]

Now consider new ambiguities formed by this relation with the old ones. The ambiguity \( xy^{2n+3}x^2 \) is resolvable. The ambiguity

\[ y^{2n+3}x \to y^{2n+6} \to c'y^{2n+6+k}(1 + v(y)), \]

\[ \ldots \]
where \( k \) is degree of \( p(y) \): \( Qp(y) = c'y^k + ... \), and \( k \) odd. Since \( 1 + v(y) \) is invertible, we have a relation
\[
y^{2n+k+6} = 0.
\]
This relation does not produce any unresolvable ambiguities. Thus the Gröbner basis consists of
\[
x^2 - y^3p(y) = 0, \quad xy + yx, \quad y^{2n+3} = 0, \quad y^{2n+k+6} = 0
\]
and by this the linear basis of algebra is determined. Namely it consists of monomials which does not contain as submonomials leading terms of elements of Gröbner basis \((x > y)\).

Thus the linear basis of \( A \) is: \( y^N, xy^{N-1} \) for \( n = 0, ..., 2n+3 \), and \( y^N \) for \( N = 2n + 4, ..., 2n + k + 5 \).

We can calculate then the dimension of the algebra, when potential has a cubic term \( x^2y \). Just by counting elements of linear basis described in the proposition, we deduce the following.

**Corollary 23.** If \( k = 2n \), \( \dim A = 3(2n + 3) \), if \( k < 2n \), \( \dim A = 4n + k + 9 \) (\( k \) odd), where \( k \) is degree of polynomial \( p(x) \), and \( 2n \) is degree of its even part.

This corollary, combined with the Lemma 21 provides the minimal possible dimension in case of the potential with cubic term \( x^2y \).

**Corollary 24.** Minimal possible dimension of \( A(F) \), where \( F = x^2y + F_4 + ... + F_r \), is 9.

**Proof.** In case \( p(y) \) has even degree \((k = 2n)\), the minimal possible dimension is 9 (corresponds to \( n = k = 0 \)). In case \( p(y) \) has odd degree \((k < 2n)\), the minimal possible dimension is 14 (corresponds to \( n = k = 1 \)).

### 4.2 Potential with cubic term \( x^3 \)

Let us consider now potential with cubic term \( x^3 \). This one provides the fastest growth of the three.

**Lemma 25.** Let \( A = \mathbb{K}[\langle x, y \rangle]/\text{id}_{\mathbb{K}[\langle x, y \rangle]}(\partial_x F, \partial_y F) \) for the potential \( F \in \mathbb{K}(x, y), F = x^3 + F_4 + ... + F_r \). Then \( \dim A \geq 10 \).

**Proof.** As in the previous lemma \( A_1/A_2 = \text{span} < x, y >_{\mathbb{K}} \). Since \( \partial_x F = x^2 + F_3 + F_4 + ... + F_r \), \( \partial_y F = F_3 + F_4 + ... + F_k \), the \( A_2/A_3 = \text{span} < xy, yx, y^2 >_{\mathbb{K}} \) consists only of monomials without submonomial \( x^2 \). Then \( A_3/A_4 \) spanned by 2-normal monomials \( y^3, xy^2, y^2x, xyx, yxy \), the relation \( \partial_y F \) which has term of (lower) degree 3 is the only one which can create one linear dependence between them \( \text{mod} A_4 \). Thus \( \dim A_3/A_4 \geq 4 \), and we get \( \dim A \geq 1 + 2 + 3 + 4 = 10 \).
4.3 Potential with cubic term $x^3 + y^3$

Now we consider the case of potential with $F_3 = x^3 + y^3$, which can provide algebras of dimension 8. Our goal will be to prove the following.

**Theorem 26.** There is only one up to isomorphism algebra

$$A = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}_{\mathbb{K}\langle\langle x, y \rangle\rangle}(\partial_x F, \partial_y F)$$

which has dimension 8. It is the algebra given by the potential $F = x^3 + y^3 + xyxy\,\partial_x$.

**Proof.** As before $A_1/A_2 = \text{span} < x, y >_{\mathbb{K}}$. Since $\partial_x F_3 = x^2, \partial_y F_3 = y^2, A_2/A_3 = \text{span} < xy, yx >_{\mathbb{K}}$. The 3-normal monomials are $xyx, yxy$. The linear dependences between them would not occur because $x^2$ and $y^2$ form a Gröbner basis. Thus dimension of $A_2/A_3$ is 2.

Then $A_3/A_4$ is spanned by 3-monomials $xyx, yxy$. The relation between them can not occur from generating monomials $x^2$ and $y^2$ of the ideal, which trivially form a Gröbner basis. Hence dim $A_3/A_4 = 2$.

Then $A_4/A_5$ is spanned by $xyxy, yxyx$. Let us see which relations on degree 4 monomials we can have. The relations come from resolution of ambiguities $x^3 = x^2 \cdot x = x \cdot x^2$ and $y^3 = y \cdot y^2 = y^2 \cdot y$.

These ambiguities produce polynomials $[\partial_x, x]$ and $[\partial_y, y]$. We know that they are linearly dependant, since there is a syzygy $[\partial_x, x] + [\partial_y, y] = 0$ so we have maximum one relation. These both also can be zero. In the first case dim $A_4/A_5 = 1$, in the second, dim $A_4/A_5 = 2$. If dim $A_4/A_5 = 2$, then, dim $A_5/A_6$ is 2 (if the same ambiguities do not produce nontrivial new relations of degree 5) or 1 (if these ambiguities do produce a relation of degree 5). In both cases whether dim $A_5/A_6$ is equal to 2 or 1, we already reached dimension 10 or 11. Thus the only interesting for us here case, which can lead to dimension 8, or potentially 9, is when dim $A_4/A_5 = 1$.

We will see that, in fact, it is necessarily lead to dim 8, and dim 9 is impossible. Indeed, if we have one linear dependance between 4-normal monomials $xyxy$ and $yxyx$, then $xyxy = \alpha yxyx$. If we consider now 5-normal monomials, they should be $xyxy$ and $yxyx$, but both of them on the other hand equal to $xyxyx = \alpha yxyxx = 0$ and $yxyxy = \alpha yxyxx = 0$, since $x^2 = y^2 = 0$. Thus dimension of $A_5/A_6$ must be 0.

**Remark.** As a consequence of this argument we see that dimension 9 can not occur from the potential with cubic part $x^3 + y^3$.

Now we need to find out how many non-isomorphic algebras can have a potential of the type $F = x^3 + y^3 + F_3 + ... + F_r$.

To prove that there is only one, we find changes of variables which preserve $F_3 = x^3 + y^3$ and kill all terms in the potential of degree four but $xyxy\,\partial_x$. Namely:

$$x \to x + \alpha y^2, \quad x \to x + \alpha xy, \quad x \to x + \alpha x^2, \quad x \to x + \alpha y^2, \quad \text{and}$$

$$y \to y + \alpha xy, \quad y \to y + \alpha y^2.$$

Note that these changes of variables are all invertible transformations in $\mathbb{K}\langle\langle x, y \rangle\rangle$ (see Proposition 14), thus we get isomorphic objects. This proves that there exists only
one up to isomorphism algebra of dimension 8, $F_3 = x^3 + y^3$, it is given by the potential $x^3 + y^3 + xyxy \bigcirc$.

\section{Classification in dimension 9}

As we have seen before the potential with cubic term $x^3 + y^3$ can not give dimension 9 (see remark in previous section), and as shown in Section 25 in the case of potential with cubic term $x^3$ the dimension is bigger than 10. Thus only the potential with cubic term $xy^2 \bigcirc$ can give dimension 9.

By Proposition 22 we get dimension 9 only when $n = 0$, that is the potential is $P = xy^2 \bigcirc + y^4 p(y)$, where $p(y) = 1 + c_1 y + ... + c_s y^s$.

Since we consider the case dim $A = 9$, we can see that dim $A_6 = 0$: the series of dimensions is dim $A_0 = 1$, dim $A_1 = 2$, dim $A_3 = 2$, dim $A_4 = 1$, dim $A_5 = 1$: $1 + 2 + 2 + 2 + 1 + 1 = 9$.

Thus the potential should have the form: $P = xy^2 \bigcirc + y^4 + cy^5$.

Now notice the following. We can kill the term $y^6$ in the potential by the invertible change of variables: $x \to x, y \to y + cy^3$.

Thus the potential can be taken into the form:

$P = xy^2 \bigcirc + y^4 + cy^5$.

This gives two 9 dimensional algebras, depending on whether $c = 0$ or $c \neq 0$:

$P_1 = x^2 y \bigcirc + y^4, P_2 = x^2 y \bigcirc + y^4 + cy^5, c \neq 0$.

Of course, if $c \neq 0$ then by the scaling we can make $c = 1$. So, finally the only thing remained to prove the classification of 9 dimensional algebras is the following.

\textbf{Theorem 27.} Algebras given by the potentials

$P_1 = x^2 y \bigcirc + y^4, P_2 = x^2 y \bigcirc + y^4 + y^5$

are not isomorphic:

$A_1 = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(\partial_x P_1, \partial_y P_1) \neq A_2 = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(\partial_x P_2, \partial_y P_2)$.

\textbf{Proof.} We need to show that algebras $A_1 = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(R_1)$ non-isomorphic to $A_2 = \mathbb{K}\langle\langle x, y \rangle\rangle/\text{id}(R_2)$, where

$R_1 : xy + yx, x^2 + y^3$, 

$R_2 : xy + yx, x^2 + y^3 + y^4$.

Let us consider corresponding algebras $A'_1 = \mathbb{K}\langle x, y \rangle/\text{id}(R_1)$, $A'_2 = \mathbb{K}\langle x, y \rangle/\text{id}(R_2)$, and calculate their Gröbner bases (as an ideal in free algebra) for $x < y$. We get that the Gröbner bases of $R_1$ is:

$xy + yx, x^2 + y^3, x^3$
The first algebra is nilpotent, which implies $A_1' = \overline{A_1} = A_1$. When we calculate the Gröbner bases of $R_2$, we see that relation $y^6 = y^7 p(y)$ holds, thus $A_2 = A_2'(y^6)$. So, we reduced the problem to isomorphism of two algebras: $A_1 = \mathbb{K}(x, y)/(R_1)$ and $A_2 = \mathbb{K}(x, y)/(R_2, y^6)$.

Now looking at the Gröbner bases of both of them we see that linear bases for them consist of monomials:

$$A_1 : 1, x, y, x^2, yx, y^2, yx^2, y^2 x, y^2 x^2$$

$$A_2 : 1, x, y, x^2, yx^2, y^2 x, y^3.$$

Another possible linear basis for both algebras is:

$$1, x, y, y^2, yx, y^2 x, y^3, y^4, y^5.$$

Multiplication table in this basis for $A_1$ and $A_2$ are as follows.

In $A_1$:

$$x^2 = -y^3 - y^4, xy = -yx, xy^2 = y^2 x, yxy = y^4 + y^5,$$

$$xy^2 x = -y^5, xy^3 = 0, xy^4 = 0, xy^5 = 0, y^6 = 0,$$

$$y^3 x = 0, yx^2 = -y^4 - y^5, yxy^2 x = 0, y^2 x^2 = -y^5 \ldots$$

In $A_2$:

$$x^2 = -y^3, xy = -yx, xy^2 = y^2 x, yxy = y^4,$$

$$xy^2 x = -y^5, xy^3 = 0, xy^4 = 0, xy^5 = 0, y^6 = 0,$$

$$y^3 x = 0, yx^2 = -y^4, y^2 x^2 = -y^5 \ldots$$

Using this linear basis rewrite relations in a more convenient way:

$$A_1 : x^2 = -y^3, xy = -yx, xy^2 = 0$$

$$A_2 : x^2 = -y^3 - y^4, xy = -yx, xy^3 = 0, x^3 = 0, y^6 = 0.$$

Look for isomorphism $\phi : A_1 \rightarrow A_2$, $\phi(x) = \tilde{x}, \phi(y) = \tilde{y}$ with undetermined coefficients:

$$\tilde{x} = a_1 x + a_2 y + a_3 yx + a_4 y^2 + a_5 y^2 x + a_6 y^3 + a_7 y^4 + a_8 y^5$$

$$\tilde{y} = b_1 x + b_2 y + b_3 yx + b_4 y^2 + b_5 y^2 x + b_6 y^3 + b_7 y^4 + b_8 y^5.$$

Isomorphism means we should have:

$$\tilde{x} = -\tilde{y}^3 - \tilde{y}^4, \tilde{x}\tilde{y} = -\tilde{y}\tilde{x}, \tilde{x}\tilde{y}^4 = 0, \tilde{x}^3 = 0, \tilde{x}^6 = 0.$$

From this we derive the following conditions on coefficients.

$$\tilde{x}^3 = 0 \implies \tilde{x}^3 = a_2^3 y^3 + a_1 a_2^2 y^2 x + \ldots = 0 \implies a_2 = 0.$$
Now \( \tilde{x}^3 = -3a_1^2a_4y^5 \Rightarrow a_4 = 0 \), since \( \tilde{x} \notin A_2^2 \Rightarrow a_1 \neq 0 \).

Moreover,
\[
\tilde{x} \tilde{y} + \tilde{y} \tilde{x} = 0 \implies \tilde{x} \tilde{y} + \tilde{y} \tilde{x} = -2a_1b_1y^3 + ... \implies b_1 = 0.
\]

Note that \( \tilde{x}, \tilde{y} \) are independent modulo \( A_2^2 \Rightarrow b_2 \neq 0 \). We have further
\[
a_1b_4y^2x + ... \implies b_4 = 0, 2a_6b_2y^4 + ... \implies a_6 = 0.
\]

Rewrite \( \tilde{x}, \tilde{y} \) substituting coefficients we found:
\[
\tilde{x} = a_1x + a_3yx + a_5y^2x + a_7y^4 + a_8y^5
\]
\[
\tilde{y} = b_2y + b_3yx + b_5y^2x + b_7y^4 + b_8y^5.
\]

We have also \( \tilde{x}^2 + \tilde{y}^2 + \tilde{y}^4 = 0, \)
\[
\tilde{x}^2 = a_1^2 + a_3a_5(xy^2 + yx^3) + a_3^2yxyx + a_1a_5(xy^2 + y^2x^2)
\]
\[
\tilde{y}^3 = b_2y^3 + 3b_2b_5y^5, \tilde{y}^4 = b_4y^4 \implies b_2 = 0.
\]
This is the contradiction with what we noticed before: \( b_2 \neq 0 \). Thus the isomorphism does not exist. \(\square\)

### 6 Associated graded structures of filtered braces

Let \( B \) be the brace with filtration \( B = \bigcup B_i, B_{i+1} \subseteq B_i, B_i \ast B_j \subseteq B_{i+j}, \) we also suppose \( \bigcap_{i=1}^\infty B_i = 0. \) As usual, we say that element \( x \) has degree \( i \) with respect to this filtration if \( x \in B_i, x \notin B_{i-1}. \) Nilpotent braces are naturally endowed with such filtration.

We will later consider also a completion \( \hat{B} \) of \( B \) with respect to a topology, defined by the given filtration. We can think of the completion \( \hat{B} \) as a set consisting of infinite series \( \sum_{i=1}^\infty r_i, r_i \in B_i. \) For details of the completion construction see, for example, \([2]\) chapter 8.

There is a natural filtration on \( \hat{B}: \hat{B} = \bigcup \hat{B}_i, \hat{B}_{i+1} \subseteq \hat{B}_i, \hat{B}_i \ast \hat{B}_j \subseteq \hat{B}_{i+j}, \bigcap_{i=1}^\infty \hat{B}_i = 0, \) where \( \hat{B}_i \) consists of infinite series of degree \( i. \) We say here that degree of series \( \sum_{i=1}^\infty r_i \) is \( i \) if \( r_i \neq 0, r_m = 0 \) for \( m < i. \)

With respect to the filtration on \( B \) we can consider associated graded structure \( B_{gr} = \bigoplus B_i/B_{i+1} = \bigoplus \hat{B}_i \) with multiplication defined in the following way: for \( a_i \in B_i, b_j \in B_j \)
\[
a_i \ast b_j = a_i \ast b_j + B_{i+j+1}
\]
Then we extend it to arbitrary (non-homogeneous) elements using left and right distributivity, which holds in \( B_{gr}, \) because of the nature of the left brace identity. Indeed,
(a + b + a * b) * c = a * c + b * c + a * (b * c)

for \( a \in B_i, b \in B_j, c \in B_k \) means \( (a + b) * c = a * c + b * c + B_r, r = \max(i, j) + k + 1 \). Thus in \( B_{gr} \) we have right distributivity

\[(a + b) * c = a * c + b * c\]

for \( a \in \hat{B}_i, b \in \hat{B}_j, c \in \hat{B}_k \). The left distributivity holds in \( B \) itself, so trivially in \( B_{gr} \) as well. Now using two-sided distributivity in \( B_{gr} \) we can correctly define multiplication in \( B_{gr} \) by extending it from homogeneous elements: for arbitrary \( a, b \in B_{gr}, a = a_1 + ... + a_n, b = b_1 + ... + b_m, a_i \in \hat{B}_i, b_j \in \hat{B}_j \)

\[(a * b)_k = \sum_{i=1}^{k-1} a_i * b_{k-i} + B_{k+1} \].

So, this construction correctly defines multiplication since the brace axiom \((a + b + a * b) * c = a * c + b * c + a * (b * c)\) supplied us with the right distributivity in the associated graded \( B_{gr} \).

**Proposition 28.** Let \((B, +, *)\) be a set with two operations endowed with decreasing filtration: \( B = \bigcup B_i, B_{i+1} \subset B_i, B_i \ast B_j \subset B_{i+j} \). Consider associated graded space \( B_{gr} = \oplus B_i / B_{i+1} = \oplus \hat{B}_i \). If for \( a \in B_i, b \in B_j, c \in B_k \), \((a + b) * c = a * c + b * c + B_r,\) and \( a * (b + c) = a * b + a * c + B_r, r = \max(i, j) + k + 1,\) then \( B_{gr} \) with multiplication extended from homogeneous components: \( a, b \in B_{gr}, a = a_1 + ... + a_n, b = b_1 + ... + b_m, a_i \in \hat{B}_i, b_j \in \hat{B}_j \)

\[(a * b)_k = \sum_{i=1}^{k-1} a_i * b_{k-i} + B_{k+1} \]

is correctly defined.

We can analogously associate a graded structure for the completion, which by definition is the direct product of quotients of elements of filtration of \( B \) (which are isomorphic to quotients of elements of filtration of \( \hat{B} \)).

\[\hat{B}_{gr} = \prod_{i=1}^{\infty} B_i / B_{i+1} = \prod_{i=1}^{\infty} \hat{B}_i / \hat{B}_{i+1} \).

Since \( \bigcap B_i = 0 \) we have \( B \subset \hat{B} \) is a subbrace of the completion and \( B_{gr} \) is obviously a subbrace of \( \hat{B}_{gr} \).

**Theorem 29.** Let \( B \) be a left brace endowed with descending filtration \( B = \bigcup B_i \) where \( B_i \subset B, B_{i+1} \subset B_i, B_i \ast B_j \subset B_{i+j} \), satisfying \( \bigcap_{i=1}^{\infty} B_i = 0 \), then the associated graded \( B_{gr} = \oplus B_i / B_{i+1} = \oplus \hat{B}_i \) with multiplication defined above is a pre-Lie algebra.
For the proof of the theorem we are going first to extend the right distributivity formula in lemma 15 proved in [23] for the nilpotent case to the case of an arbitrary descending ideal filtration with zero intersection. To write down the formula we should extend our realm to the completion $\hat{B}$ of $B$, with respect a given filtration.

**Lemma 30.** Let $B$ be a left brace endowed with the descending filtration $B = \bigcup B_i$ where $B_i$ are ideals in $B$, $B_{i+1} \subset B_i$, $B_i \ast B_j \subset B_{i+j}$, satisfying $\bigcap_{i=1}^{\infty} B_i = 0$. Then the right distributivity formula holds in $\hat{B}$:

$$(a + b) \ast c = a \ast c + b \ast c + \sum_{i=1}^{\infty} (-1)^{i+1}(d_i \ast d_i') \ast c - d_i \ast (d_i' \ast c).$$

Here $a, b, c \in B$, $d_0 = a, d_0' = b$ and for $i \geq 1$ they are defined as $d_i = d_{i-1} + d_i' - d_i'$.

**Proof.** This is a direct consequence of the lemma 15 proved in [23] in the nilpotent case. Indeed, the equality we need to prove should hold in infinite series, and series coincide means they coincide componentwise (here zero intersection of the filtration is important). For any $n$ we consider now a nilpotent algebra $B/B_n$ and apply to it the lemma, this is possible since filtration components $B_n$ are ideals in $B$. We get a formula in $B/B_n$, which means the series are coincide up to $n$th term. Since it is true for any $n$ this proves the statement.

Now we notice one consequence of the formula from previous lemma, which holds in infinite series (completion) corresponding to the filtration.

**Corollary 31.** In the setting of previous lemma for arbitrary infinite series from the completion corresponding to given filtration $a, b, c \in B, u_r \in \hat{B}$. If $\deg a < \deg b$, then

$$(a + b) \ast c = a \ast c + b \ast c + u_r,$$

where $\deg u_r > \deg b + \deg c$.

**Proof.** This can be seen directly from the formula in Lemma 30 above.

**Lemma 32.** If for $a, b, c \in B, u_r \in \hat{B}$ the property

$$(a + b) \ast c = a \ast c + b \ast c + u_r,$$

where $\deg u_r > \deg b + \deg c$ holds, then $B_{gr}$ is a pre-Lie algebra.

**Proof.** According to the brace axiom we have

$$(a + b + a \ast b) \ast c = a \ast c + b \ast c + a \ast (b \ast c),$$

and if we permute $a$ and $b$ we get

$$(b + a + b \ast a) \ast c = b \ast c + a \ast c + b \ast (a \ast c).$$
Now due to the property from the corollary we can present the left hand side as
\[
((a + b) + a \ast b) \ast c = (a + b) \ast c + (a \ast b) \ast c + u_r
\]
with \( \deg u_r > \deg a \ast b + \deg c \) and
\[
((b + a) + b \ast a) \ast c = (b + a) \ast c + (b \ast a) \ast c + v_r
\]
with \( \deg v_r > \deg b \ast a + \deg c \). Hence
\[
(a + b) \ast c + (a \ast b) \ast c + u_r = a \ast c + b \ast c + a \ast (b \ast c)
\]
and
\[
(b + a) \ast c + (b \ast a) \ast c + v_r = b \ast c + a \ast c + b \ast (a \ast c).
\]
Subtracting these two we get
\[
(a \ast b) \ast c - a \ast (b \ast c) = (b \ast a) c - b \ast (a \ast c) + u_r + v_r,
\]
hence in \( B_{gr} \) we have left-symmetric identity.\hfill \Box

Proof. The combination of the corollary and Lemma 32 completes the proof of the theorem. \hfill \Box

7 Associated graded structures to trusses and pre-Lie algebras

The notion which incorporates the notion of a ring and of a brace was introduced by T. Brzezinski [5] and called truss (because the defining law is holding both structures together).

**Definition 33.** A set \((A, \circ, +)\) with two binary operations is called a truss, if \((A, +)\) is an abelian group, \((A, \circ)\) is a semigroup and
\[
a \circ (b + c) + a = a \circ b + a \circ c + \alpha(a)
\]
where \( \alpha \) is some function \( \alpha : A \to A \).

If we rewrite this definition in terms of operation \(a \ast b = A \circ b - a - b\), from the axiom of associativity in \((A, \circ)\) we get the same axiom as in brace:
\[
(a \ast b + a + b) \ast c = a \ast c + b \ast c + a \ast (b \ast c)
\]
and from the above axiom we get
\[
a \ast (b + c) = a \ast b + a \ast c + \alpha(a).
\]

We will use axioms of truss in this form. Let now \( B \) be a truss endowed with descending ideal filtration with zero intersection. Under mild condition on \( \alpha \), we can consider associated graded to this filtration, and show that it carries a structure of a pre-Lie algebra.
Corollary 34. Let $B$ be a truss endowed with descending filtration $B = \bigcup B_i$ where $B_i \triangleleft B$, $B_{i+1} \subset B_i$, $B_i \ast B_j \subset B_{i+j}$, satisfying $\bigcap_{i=1}^{\infty} B_i = 0$, and such that $\deg \alpha(a) > 2$. Then the associated graded structure $B_{gr} = \bigoplus B_i / B_{i+1} = \bigoplus \bar{B}_i$ is a pre-Lie algebra.

Proof. The same argument as in previous section shows that the associated graded $B_{gr}$ is well defined, since the correcting term $\alpha$ have big enough degree: $\deg \alpha(a) > 2$. Then based on the first axiom of the truss (in terms of $*$), which do coincide with the axiom of brace, we used in the proofs in previous section, we can see literally in the same way as for braces, that the associated graded algebra is a pre-Lie algebra. \qed
