We derive an analytical expression for the scattering amplitude of two ultracold atoms of arbitrary spin and with general spin-orbit (SO) coupling, on the basis of our recent work (Phys. Rev. A 86, 053608 (2012)). As an application, we demonstrate that SO coupling can induce scattering resonance in the case with finite scattering length. The same approach can be applied to calculate the two-body bound state of SO-coupled ultracold atoms. For the ultracold spin-1/2 fermi gases in three- or two- dimensional systems with SO coupling, we also obtain the renormalization relation of effective contact interaction with momentum cutoff, as well as the applicability of Huang-Yang pseudo-potential.

I. INTRODUCTION

In the study of ultracold gases it is very important to understand the low-energy scattering properties of atoms. First, the two-body and three-body collisions are the underlying physics of many important experimental phenomena, e.g., the two-body decay and three-body recombination. Second, understanding the behavior of the low-energy inter-atomic scattering amplitudes is indispensable in designing the effective inter-atomic interactions (e.g., the Huang-Yang pseudo-potential, Bethe-Peierls boundary condition and the contact interaction with momentum cutoff), which are widely used in the theoretical calculations. In the low-energy cases the effective interaction and the realistic interaction potential should lead to the same two-body scattering amplitude.

In recent years, a class of synthetic gauge fields and spin-orbit (SO) coupling has been realized in ultracold Bose gases and degenerate Fermi gases with Raman laser beams. In these systems, the atomic spin is linearly coupled with the atomic spatial momentum. A considerable amount of theoretical interest has been stimulated to understand the SO-coupling effect in both many-body and few-body physics.

In this paper we provide a systematic investigation on the two-body scattering amplitude of SO-coupled ultracold atoms in three-dimensional (3D) uniform space. Our research is based on the following motivations. First, in the current experiments, the amplitude of elastic inter-atomic collision and inelastic-scattering-induced decay of ultracold gases have been directly observed in the systems with SO coupling. The theoretical investigation for the two-body scattering amplitude is necessary to explain this kind of observations. In particular, the calculation of the inelastic scattering amplitudes is crucial for the study of stability of the SO-coupled ultracold gases in the metastable dressed state, e.g., the dark state. Second, as shown above, the criteria of the effective interaction in the ultracold gases is that, the effective interaction potential and the real interaction potential should lead to the same low-energy two-body scattering amplitude. Accordingly, we should first calculate the scattering amplitude given by the real potential, and then construct the correct effective interactions. This kind of work has been done for ultracold gases in quasi-one-dimensional, quasi-two-dimensional confinements and optical lattices, but it is still absent for the gases with SO coupling.

The calculation in this paper is based on our recent work where the short-range behavior of the scattering wave functions of two SO-coupled ultracold atoms in a 3D uniform system is studied and a modified Bethe-Peierls boundary condition is derived. Based on these results, in this paper we derive an analytical expression for the scattering amplitude of two atoms with arbitrary spin and SO coupling. Our approach can also be used to calculate the low-energy bound state of two spin-1/2 atoms with SO coupling. Furthermore, we show that the SO coupling can induce the scattering resonance. Namely, for the atoms with finite scattering length, the threshold scattering amplitude diverges when the SO-coupling intensity assumes some particular value. For the SO-coupled spin-1/2 fermionic atoms, we also derive the renormalization relation of 3D and pure-two-dimensional (pure-2D) effective contact interaction with momentum cutoff, as well as the applicability of Huang-Yang pseudo-potential. We find that the form of the 3D and 2D renormalization relation is not changed by the SO coupling. Nevertheless, in the presence of SO coupling the physical parameters, i.e., the scattering length in the 3D case and bound-state binding energy in 2D case, should be replaced by the ones which are related to the SO coupling. Furthermore, we also find that the Huang-Yang pseudo-potential cannot be directly used in the presence of SO-coupling.

The remainder of this manuscript is organized as follows. In Sec. II, we derive the exact analytical expression for the scattering amplitude of SO-coupled ultracold...
atoms, and show the approach for the calculation of two-atom bound states. In Sec. III, we illustrate the scattering resonance induced by SO coupling. The renormalization relation of effective contact interaction and the applicability of Huang-Yang pseudo-potential is investigated in Sec. IV. The main results are summarized and discussed in Sec. V, while some details of our calculations are explained in the appendixes.

II. SCATTERING AMPLITUDE AND BOUND STATE OF SO-COUPLED ATOMS

A. Spin-1/2 fermionic atoms

We first consider the scattering amplitude of two SO-coupled spin-1/2 fermionic atoms in 3D space. In this paper we use the word “SO coupling” to refer to the linear coupling between atomic spin and momentum, e.g., the ones realized in the current experiments with Raman laser beams. Without loss of generality, the single-atom Hamiltonian of such a system can be written as

\[ H_{1b} = \hat{r}^2/2 + \lambda \hat{M} \cdot \hat{P} + Z, \]

(1)

where \( \hat{P} \) is the atomic momentum, and \( \hat{M} \) and \( Z \) are operators in spin space (here we have used \( h = 1 \) and the atomic mass \( m = 1 \)). The term \( \lambda \hat{M} \cdot \hat{P} \) describes the SO coupling and \( Z \) accounts for the residual spin-dependent part. Here, the eigen-values of \( \hat{M} \) are of the order of unity, and \( \lambda \) indicates the intensity of the SO coupling. It is pointed out that the term \( \lambda \hat{M} \cdot \hat{P} \) in Hamiltonian in Eq. (1) can be used to describe arbitrary type of linear spin-momentum coupling. For instance, for effective spin-1/2 systems in Refs. [11] [12], one has \( \lambda = 2k_r \), \( \hat{M} = (\hat{\sigma}_z, 0, 0) \) and \( Z = 2\delta \hat{\sigma}_z + \Omega \hat{\sigma}_y/2 \) where \( \delta \) is the two-photon detuning, \( k_r \) is the recoil momentum, \( \Omega \) is the Raman-coupling strength, and \( \hat{\sigma}_{x,y,z} \) is the Pauli operator. Similarly, for the system with Rashba SO-coupling in the 3D space, we have \( \hat{M} = (\hat{\sigma}_x, \hat{\sigma}_y, 0) \).

For the two-atom scattering problem, the Hilbert space \( \mathcal{H} \) can be expressed as \( \mathcal{H} = \mathcal{H}_r \otimes \mathcal{H}_{a1} \otimes \mathcal{H}_{a2} \), with \( \mathcal{H}_r \) for the inter-atomic relative motion in the spatial space, and \( \mathcal{H}_{a_i} \) for the \( i \)-th atom. In this paper we use \( |\rangle \rangle \) to denote the state in \( \mathcal{H}_r \) for the state in \( \mathcal{H}_r \), \( |\rangle \rangle \) for the state in \( \mathcal{H}_{a1} \otimes \mathcal{H}_{a2} \), and \( |\rangle \rangle_i \) for the state in \( \mathcal{H}_{a_i} \). In Secs. II, III and Sec. IV.C we work in the representation of inter-atomic relative position, where the state \( |\psi\rangle \) is described by the “spinor wave function” \( |\psi(\vec{r})\rangle \equiv (\vec{r}|\psi\rangle) \). Here \( |\vec{r}\rangle \) is the eigen-state of the inter-atomic relative position with corresponding eigen-value \( \vec{r} = (x, y, z) \). It is clear that \( |\psi(\vec{r})\rangle \) can also be considered as a \( \vec{r} \)-dependent spin state.

The total Hamiltonian of the two atoms is given by

\[ H_{1b}^{(1)} + H_{1b}^{(2)} + U(\vec{r}), \]

where \( H_{1b}^{(i)} \) (\( i = 1, 2 \)) is for the \( i \)-th atom, and \( U(\vec{r}) \) is the spin-dependent interaction potential between the two atoms. Because the total momentum of the two atoms is conserved, the relative motion of these two can be separated from their mass-center motion. The Hamiltonian for the relative motion is then

\[ H = \hat{p}^2 + \lambda \vec{c} \cdot \hat{P} + B(\vec{K}) + U(\vec{r}) \equiv H_0 + U(\vec{r}), \]

(2)

where \( \hat{P} \) is the relative-momentum operator of the two atoms. In the \( \vec{r} \)-representation we have \( \hat{P} = -i \nabla \). The total momentum \( \vec{K} = \vec{P}^{(1)} + \vec{P}^{(2)} \) of the two atoms is conserved during the scattering process, and behaves as a constant in our calculation. The operators \( \vec{c} \) and \( B(\vec{K}) \) read

\[ \vec{c} = \vec{M}^{(1)} - \vec{M}^{(2)}, \]

(3)

\[ B(\vec{K}) = Z^{(1)} + Z^{(2)} + \frac{\lambda}{2} \vec{K} \cdot (\vec{M}^{(1)} + \vec{M}^{(2)}). \]

(4)

In the stationary scattering theory, the incident state is regarded as the eigen-state of the Hamiltonian \( H_0 \) for the free motion of the two fermionic atoms. With the Pauli’s principle being taken into account, such an incident state for two spin-1/2 fermionic atoms can be expressed as

\[ |\Psi^{(0)}(\vec{r})\rangle = \frac{e^{i\vec{k}\cdot\vec{r}}}{4\pi\sqrt{2}}|\alpha, \vec{k}\rangle - \frac{e^{-i\vec{k}\cdot\vec{r}}}{4\pi\sqrt{2}}P_{12}|\alpha, \vec{k}\rangle, \]

(5)

with \( \vec{k} \) the relative momentum of the two atoms and \( P_{12} \) the permutation operator of the spin of the two atoms. Here the state \( |\alpha, \vec{k}\rangle \) (\( \alpha = 1, 2, 3, 4 \)) of the two-atom spin is defined as the \( \alpha \)-th eigen-state of the operator \( h_0(\vec{k}) \equiv \lambda \vec{c} \cdot \vec{K} + B(\vec{K}) \), with eigen-energy \( E(\alpha, \vec{K}, \vec{k}) \). The symbol satisfies \( \alpha > \alpha' \) when \( E(\alpha, \vec{K}, \vec{k}) \geq E(\alpha', \vec{K}, \vec{k}) \). In this paper, we denote

\[ t = (\alpha, \vec{K}, \vec{k}) \]

(6)

as the set of these three quantum numbers. It is easy to prove that \( |\Psi_{1}(\vec{r})\rangle \) in Eq. (5) is an eigen-state of \( H_0 \) with eigen-energy

\[ E_t = k^2 + E(\alpha, \vec{K}, \vec{k}). \]

(7)

In this paper, we assume that \( U(\vec{r}) \) is a short-range potential with effective range \( r_s \). In the region \( r \equiv |\vec{r}| > r_s \), we have \( U(\vec{r}) \approx 0 \) and further the low-energy scattering state \( |\Psi^{(+)}(\vec{r})\rangle \) with respect to the incident state \( |\Psi^{(0)}(\vec{r})\rangle \) can be expressed as

\[ |\Psi^{(+)}_{1}(\vec{r})\rangle \approx |\Psi^{(0)}_{1}(\vec{r})\rangle + B_1 G_0 (E_t; \vec{r}, 0) |S\rangle, \]

(8)

with \( |S\rangle = (|\uparrow\rangle_1 |\downarrow\rangle_2 + |\downarrow\rangle_1 |\uparrow\rangle_2)/\sqrt{2} \) the singlet spin state. Here \( B_1 \) is a \( \vec{r} \)-independent constant and related with \( |\Psi^{(+)}_{1}(\vec{r})\rangle \) through the relation

\[ \int d\vec{r}' U(\vec{r}')|\Psi^{(+)}_{1}(\vec{r}')\rangle = B_1 |S\rangle. \]

(9)

For details, see Appendix A. In Eq. (5) the free Green’s function \( G_0 (\eta; \vec{r}, \vec{r}') \) is defined as

\[ G_0 (\eta; \vec{r}, \vec{r}') = \frac{1}{\eta + i0^+ - H_0} \delta (\vec{r} - \vec{r}'), \]

(10)
and is a $(\vec{r}, \vec{r}')$-dependent operator for the two-atom spin. In this paper we consider the low-energy case with $k \ll 1/r_*$, and further assume that the SO coupling is weak enough so that $\lambda \ll 1/r_*$. Furthermore, we have proved \(^{[4]}\) that, in the short-range region $r_* \lesssim r \ll 1/k$ the function $|\Psi_{\uparrow}^{(+)}(\vec{r})|$ behaves as

$$|\Psi_{\uparrow}^{(+)}(\vec{r})| \propto \left( \frac{1}{r} - \frac{1}{a_0} \right) |S| - i \frac{\lambda}{2} \vec{c} \cdot (\vec{r}/r) |S|. \quad (11)$$

Here, the scattering length $a_0$ is determined by both the detail of the potential $U(\vec{r})$ and the SO coupling. In some special systems, e.g., the systems with $[U(\vec{r}), \vec{c}] = 0$ and those in the current experiments \([4]\), the scattering length $a_0$ is independent of the SO coupling and takes the same value as the scattering length in the systems without SO coupling \([5]\).

We can now calculate the coefficient $B_t$ in Eq. (5) and the inter-atomic scattering amplitude. As in Refs. \([4, 5]\), $B_t$ can be obtained from Eq. (11) and the behavior of $G_0(\eta; \vec{r}, \vec{r}')|S|$ in the short-range region $r_* \lesssim r \ll 1/k$. With calculations shown in Appendix B, we find that

$$G_0(\eta; \vec{r}, 0) \approx \frac{1}{4\pi} \left( \frac{1}{r} + i \eta^{1/2} \right) + F(\eta) + i \frac{\lambda}{8\pi} \vec{c} \cdot (\vec{r}/r). \quad (12)$$

where the operator $F(\eta)$ is defined as

$$F(\eta) = \frac{1}{(2\pi)^3} \int d\vec{k}' F(\eta, \vec{k}'), \quad (13)$$

where

$$F(\eta, \vec{k}') = \sum_{\alpha''} \left( \frac{\langle \alpha'', \vec{k}' | \alpha'' | \alpha', \vec{k}'' \rangle}{\eta + i0^+ - E_{\alpha''}} - \frac{|\alpha'', \vec{k}' | \langle \alpha', \vec{k}'' \rangle}{\eta + i0^+ - k'^{\prime 2}} \right), \quad (14)$$

with $t'' = (\alpha'', \vec{K}, \vec{k}''')$ and $k'' = |\vec{k}''|$. It is clear that the fact $\lim_{|\vec{k}| \to \infty} h_0(\vec{k}) = \lambda \vec{c} \cdot \vec{k}$ gives $\lim_{k' \to \infty} \left[ F(\eta, \vec{k}') + F(\eta, -\vec{k}') \right] \propto 1/k'^4 + O(1/k'^5)$. Therefore, using \( \int d\vec{k}' = \int_0^\infty k'^{3/2}dk'' \int d\Omega_{\vec{k}''}, \) with $\Omega_{\vec{k}''}$ the solid angle of $\vec{k}''$, it is easy to prove that the integration in the r.h.s. of Eq. (13) can be re-expressed as $F(\eta) = (2\pi)^{-3} \int d\vec{k}' [F(\eta, \vec{k}') + F(\eta, -\vec{k}')] / 2$. Such an expression maybe convenient for the numerical calculation of the integration.

Substituting Eq. (12) into Eq. (8), we get the expression for $|\Psi_{\uparrow}^{(+)}(\vec{r})|$ in the short-range region

$$|\Psi_{\uparrow}^{(+)}(\vec{r})| = |\Psi_{\uparrow}^{(0)}(0)\rangle + iB_t \frac{\lambda}{8\pi} \vec{c} \cdot (\vec{r}/r) |S\rangle + B_t \left[ - \frac{1}{4\pi} \left( \frac{1}{r} + iE_t^{1/2} \right) + F(E_t) \right] |S\rangle \quad (15)$$

Comparing Eq. (15) to Eq. (11) and using the fact that $F(\eta)|S\rangle \propto |S\rangle$, we obtain

$$B_t = \frac{4\pi |\Psi_{\uparrow}^{(0)}(0)\rangle}{1/a_0 + i E_t^{1/2} - 4\pi |S\rangle F(E_t)|S\rangle}. \quad (16)$$

According to scattering theory \([6]\), the scattering amplitude $f(t' \to t)$ between the incident state $|\Psi_{\uparrow}^{(0)}(\vec{r})\rangle$ and an energy-conserved output state $|\Psi_{\uparrow}^{(+)}(\vec{r})\rangle$ with $t' = (\alpha', \vec{K}, \vec{k}')$ is defined as

$$f(t' \to t) = -2\pi^2 \int d\vec{r}' \langle \Psi_{\uparrow}^{(0)}(\vec{r}) | U(\vec{r}) | \Psi_{\uparrow}^{(+)}(\vec{r}') \rangle. \quad (17)$$

It is pointed out that, since $U(\vec{r}) \approx 0$ in the region $r \gtrsim r_*$, the integration in the right-hand side of the above equation is only done in the region $r \lesssim r_*$. Under the low-energy condition $k \ll 1/r_*$, in this region we have $|\Psi_{\uparrow}^{(0)}(\vec{r})| \approx |\Psi_{\uparrow}^{(0)}(0)|$, and then $f(t' \to t)$ can be re-expressed as

$$f(t' \to t) = -2\pi^2 |\Psi_{\uparrow}^{(0)}(0)| \int d\vec{r}' U(\vec{r}) |\Psi_{\uparrow}^{(+)}(\vec{r}')\rangle.$$

where we have used Eq. (9). Thus, using Eq. (16), we finally have

$$f(t' \to t) = - (2\pi)^3 |\Psi_{\uparrow}^{(0)}(0)| \frac{1}{1/a_0 + i E_t^{1/2} - 4\pi F(E_t)} |\Psi_{\uparrow}^{(0)}(0)\rangle, \quad (19)$$

with $E_t^{1/2} \equiv i \sqrt{|E_t|}$ for $E_t < 0$. This is the exact analytical expression for the low-energy scattering amplitude of two spin-1/2 fermionic atoms with SO coupling.

### B. Atoms with arbitrary spin

The above approach can be straightforwardly generalized to the general case of two fermionic or bosonic atoms with any kind of SO coupling and arbitrary spin. In these cases, the single-atom motion and the relative motion of the two atoms are still given by Eqs. (11) and (2), respectively. The incident state can be expressed as

$$|\Psi_{\uparrow}^{(0)}(\vec{r})\rangle = e^{i\vec{k} \cdot \vec{r}} \left\{ \langle \alpha, \vec{k} | \right\} \pm e^{-i\vec{k} \cdot \vec{r}} \left\{ \langle \alpha, \vec{k} | \right\}, \quad (20)$$

where $\pm$ are for the systems of bosonic an fermionic atoms, respectively.

The scattering wave function with respect to incident state $|\Psi_{\uparrow}^{(0)}(\vec{r})\rangle$ can still be denoted as $|\Psi_{\uparrow}^{(+)}(\vec{r})\rangle$. In the region with $r \gtrsim r_*$ we have (Appendix A)

$$|\Psi_{\uparrow}^{(+)}(\vec{r})\rangle \approx |\Psi_{\uparrow}^{(+)}(0)\rangle + G_0(E_t; \vec{r}, 0) |\phi\rangle. \quad (21)$$
with the $\vec{r}$-independent spin state $|\phi\rangle$ satisfies

$$|\phi\rangle = \int d\vec{r}' U(\vec{r}') |\Psi_t^{(+)}(\vec{r}')\rangle.$$  \hspace{1cm} (22)

This is very similar to Eq. 8, but the spin state $|\phi\rangle$ is not unique. Instead, $|\phi\rangle$ can be different for different incident state $|\Psi_t^{(0)}(\vec{r}')\rangle$. Furthermore, as shown in Ref. [54], in the short-range region $r_* \lesssim r \ll 1/k$ the scattering wave function $|\Psi_t^{(+)}(\vec{r}')\rangle$ behaves as

$$|\Psi_t^{(+)}(\vec{r}')\rangle = \left( \frac{1}{r} - A_R \right) |\chi\rangle - i \frac{\lambda}{2} \vec{e} \cdot \left( \frac{\vec{r}}{r} \right) |\chi\rangle.$$ \hspace{1cm} (23)

Here $|\chi\rangle$ is another $\vec{r}$-independent spin state, and $A_R$ is a $\vec{r}$-independent operator in the spin space, which is also determined by the detail of the interaction potential $U(\vec{r})$ and the SO coupling. For the cases of spin−1/2 fermionic atoms, we have $A_R = 1/a_R$, and Eq. (23) reduces to Eq. (11). As in the above section, in the current experiments [4, 10] for bosonic atoms with 1D SO coupling, $A_R$ is independent of the SO coupling. For instance, for the ultracold gases with spin−1 $^{87}$Rb atoms, we have

$$A_R = \frac{1}{a_0} P_{F=0} + \frac{1}{a_2} P_{F=2},$$ \hspace{1cm} (24)

where $a_0$ ($a_2$) is the scattering length with respect to the total atomic spin $F = 0$ ($F = 2$) and $P_{F=0,2}$ are the associated projection operators.

Using Eq. (12), we can obtain the expression of $|\Psi_t^{(+)}(\vec{r}')\rangle$ in the short-range region. Comparing such an expression with Eq. (23), we have

$$|\phi\rangle = -4\pi |\chi\rangle = \frac{4\pi}{A_R + i E_t^{1/2} - 4\pi F(E_t)} |\Psi_t^{(0)}(0)\rangle$$ \hspace{1cm} (25)

and the exact analytical expression

$$f(t' \leftarrow t) = - (2\pi)^3 \langle \Psi_t^{(0)}(0)| \frac{1}{A_R + i E_t^{1/2} - 4\pi F(E_t)} |\Psi_t^{(0)}(0)\rangle.$$ \hspace{1cm} (26)

for the scattering amplitude of SO-coupled ultracold atoms with arbitrary spin. In Ref. [10] we have used this result to quantitatively explain the collisional decay observed in our experiments with SO-coupled $^{87}$Rb atoms.

It is pointed out that, in the presence of SO-coupling, the state $|\Psi_t^{(0)}(0)\rangle$ depends on the quantum number $t = (\alpha, K, \vec{k})$, and thus changes with the direction of the atomic relative momentum $\vec{k}$. Therefore, the scattering amplitude $f(t' \leftarrow t)$ in Eq. (26) is anisotropic with respect to the directions of the incident momentum $\vec{k}$ and output momentum $\vec{k}'$. This anisotropy is also observed in the experiment by I. B. Spielman et. al. [5].

In the end of this section we consider a simple case that $A_R = 1/a$ with $a$ a constant c-number and $|a|$ is much smaller than the eigen-values of the operator $i E_t^{1/2} - 4\pi F(E_t)$. In this case Eq. (25) can be simplified as $f(t' \leftarrow t) \approx -a (2\pi)^3 \langle \Psi_t^{(0)}(0)| \Psi_t^{(0)}(0)\rangle$. This approximate result can also be obtained with Fermi’s golden rule. On the other hand, if the eigen-values of $A_R$ is comparable to or smaller than the ones of the operator $i E_t^{1/2} - 4\pi F(E_t)$, the contribution from that operator becomes significant and the Fermi’s golden rule is no longer applicable.

C. Two-atom bound state

In the above subsections we derived the analytical expression of the scattering amplitude of two ultra-cold atoms with SO-coupling. The Green’s function approach used in our calculations can also be applied to derive the low-energy bound state of two SO-coupled atoms. We denote the energy of the bound state as $E_b$, then the binding energy can be defined as $E_{\text{binding}} = -(E_b - E_{th})$, where $E_{th}$ is the energy of scattering threshold or the lowest eigen-energy of $H_0$. As shown in Appendix A, when $E_{\text{binding}} << r_*^{-2}$, the wave function $|\Psi_b(\vec{r})\rangle$ of low-energy bound state is given by

$$|\Psi_b(\vec{r})\rangle \approx N_b G_0 (E_b; \vec{r}, 0) |\phi_b\rangle,$$ \hspace{1cm} (27)

in the region $r \gtrsim r_*$. Here $N_b$ is the normalization factor and $|\phi_b\rangle$ is a $\vec{r}$-independent spin state. Furthermore, in the short-range region $r_0 \lesssim r \ll E_{\text{binding}}^{-1/2}$ $|\Psi_b(\vec{r})\rangle$ has the same behavior as the low-energy scattering state $|\Psi_s(\vec{r})\rangle$ and thus can be expressed as $|\Psi_b(\vec{r})\rangle = (1 - A_R) |\chi_b\rangle - i (\lambda/2) \vec{e} \cdot \vec{r}/r |\chi_b\rangle$, with $|\chi_b\rangle$ a $\vec{r}$-independent state in the spin space. As in the above section, with this fact and the short-range behavior of $G_0 (\eta, \vec{r}, 0)$ given by Eq. (12), we find that $|\chi_b\rangle$, $|\phi_b\rangle$ and $E_b$ can be obtained by

$$\left[ -i E_b^{1/2} + 4\pi F(E_b) \right] |\chi_b\rangle = A_R |\chi_b\rangle,$$ \hspace{1cm} (28)

$$|\chi_b\rangle = \frac{1}{4\pi} N_b |\phi_b\rangle,$$ \hspace{1cm} (29)

with $E_b^{1/2} \equiv i \sqrt{|E_b|}$ for $E_b < 0$. In particular, for two spin−1/2 fermionic atoms, we have $A_R = 1/a_R$ and $|\phi_b\rangle = |S\rangle$. Then Eq. (28) becomes

$$-i E_b^{1/2} + 4\pi \langle S| F(E_b) |S\rangle = \frac{1}{a_R}.$$ \hspace{1cm} (30)

With this equation one can obtain the bound-state energy $E_b$.

III. SO-COUPLING-INDUCED RESONANCE

In above discussions, we derive the general analytical expression (26) for the scattering amplitude of ultracold...
atoms with SO coupling. As an application, in this section we will show that SO coupling can induce scattering resonance of two ultracold atoms. For simplicity, here we only consider the scattering of two spin-1/2 fermionic atoms.

In such a system, the incident state $|\Psi_t^{(0)}(\vec{r})\rangle$ takes the form in Eq. (5), and one has $|\Psi_t^{(0)}(0)\rangle \propto |S\rangle$. Thus, the inter-atomic scattering amplitude $f(t' \leftarrow t)$ in Eq. (19) can be re-written as

$$f(t' \leftarrow t) = - (2\pi)^3 \langle \Psi_t^{(0)}(0)|S\rangle \langle S|\Psi_t^{(0)}(0)\rangle 1/a_R + d(\lambda, E_t),$$

with the function $d(\lambda, E_t)$ defined as

$$d(\lambda, E_t) = i E_t^{1/2} - 4\pi \langle S|F(E_t)|S\rangle.$$

We first consider the case of threshold scattering with $E_t = E_{th}$. In this case, we have $|\Psi_t^{(0)}(\vec{r})\rangle = |\Psi_t^{(0)}(\vec{r})\rangle$ and $d(\lambda, E_{th})$ usually takes a real value. Therefore, when the condition

$$\frac{1}{a_R} + d(\lambda, E_{th}) = 0 \quad (33)$$

is satisfied, the threshold scattering amplitude diverges and a scattering resonance occurs. Since the scattering length $a_R$ can be finite, such a resonance is induced by the SO coupling. Comparing Eq. (33) to Eq. (30), we further find that a bound state with zero binding energy appears at the resonance point. In experiments, one can observe the SO-coupling-induced resonance by tuning the scattering length or the SO-coupling intensity [61].

In Fig. 2 we plot the amplitude $f(t' \leftarrow t)$ of the threshold scattering of two spin-1/2 fermionic atoms with 1D SO coupling, i.e., $\vec{M} = (\hat{\sigma}_z, 0, 0)$ and $Z = \kappa \hat{\sigma}_z$, as in current experiments. In our calculation we assume the total momentum $\vec{K}$ of the two atoms is along the $x$-direction, i.e., $\vec{K} = (K_0, 0, 0)$. The scattering amplitudes with respect to different values of $K_0$ are illustrated versus $1/a_R$ and the SO coupling intensity $\lambda$. The appearance of resonance is clearly shown.

Next, when the scattering energy $E_t$ is larger than the scattering threshold, the function $d(\lambda, E_t)$ takes a complex value. Thus, the scattering amplitude $f(t' \leftarrow t)$ cannot diverge. Nevertheless, as a function of $1/a_R$, the absolute value of the scattering amplitude still achieves a local maximum value when the condition $\text{Re}[1/a_R + d(\lambda, E_t)] = 0$ or $1/a_R = -\text{Re}[d(\lambda, E_t)]$ is satisfied. To illustrate this effect, we also calculate

FIG. 1: (Color online) The threshold scattering scattering amplitude $f(t \leftarrow t)$ of two spin-1/2 fermionic atoms with 1D SO coupling. We plot the $f(t \leftarrow t)$ as a function of SO-coupling intensity $\lambda$ with the scattering length $a_R = 2\kappa^{-1/2}$ (a) and a function $a_R$ with $\lambda = 1.25\kappa^{1/2}$ (b). Here we have used the natural unit with $\hbar = m = 1$ and set the total momentum of the two atoms to be $\vec{K} = (K_0, 0, 0)$, with $K_0 = 0$ (black solid line), $0.3\kappa^{1/2}$ (red dashed line), $0.5\kappa^{1/2}$ (green dotted line) and $0.8\kappa^{1/2}$ (blue dashed-dotted line).

FIG. 2: (Color online) The absolute value of scattering amplitude of two spin-1/2 fermionic atoms with 1D SO-coupling. Here we plot $|f(t' \leftarrow t)|$ for the cases with $K = 0$, $\lambda = 1.25\kappa^{1/2}$ and $E_t > E_{th}$. We take $t = (2, 0, 0)$ and $t' = t_0$ (blue solid line), $t_1$ (green dashed line), $t_2$ (red dotted line) and $t_3$ (black dashed-dotted line), with $t_0, 1, 2, 3$ defined in Sec. III.
the scattering amplitude \( f(t' \leftarrow t) \) for two spin-1/2 fermionic atoms with \( \vec{M} = (\sigma_z,0,0) \) and \( Z = \lambda \sigma_z \). In Fig. 2 we plot \(|f(t' \leftarrow t)|\) versus \(1/a_R\) for the cases with \( K = 0, t = (2,0,0) \) and \( t' = t_{0,1,2,3}\) where \( t_0 = t, t_1 = (4,0,\sqrt{3} - \kappa^2/\lambda), t_2 = (4,0,\sqrt{3} - \kappa^2/\lambda - 0.8\kappa^2/2) \) and \( t_3 = (4,0,\sqrt{3} - \kappa^2/\lambda - 0.8\kappa^2/2) \). The peak behavior of the scattering amplitude is clearly illustrated.

We mention again that the resonance discussed here is essentially induced by the SO-coupling term in the Hamiltonian \( H_0 \) defined in Eq. 2. From Eq. 2 one can easily find that such a term can be omitted when \( k >> \lambda \), and therefore the SO-coupling-induced resonance is significant only when the atomic relative momentum \( k \) is small enough i.e., \( k \lesssim \lambda \). Finally, we emphasize that the calculations in this section can be directly generalized to the systems of atoms with arbitrary spin and SO coupling, and the SO-coupling-induced resonance can also appear.

**IV. EFFECTIVE INTERACTIONS**

In the many-body theory of ultracold gases, the inter-atomic interaction is usually modeled by some simple effective potentials. The most widely-used effective interactions include the Huang-Yang pseudo potential \[1\], the Bethe-Peierls boundary condition \[2\] and the contact interaction with a momentum cutoff \[3\].

For a given system, the inter-atomic scattering amplitude given by the effective inter-atomic interaction should be the same as the one from the realistic interaction potential \( U(\vec{r}) \). In our previous works \[18, 54\], we have shown that to satisfy such a condition, the Bethe-Peierls boundary condition for 3D ultracold gases, as well as the renormalization relation for the contact interaction of quasi-2D gases, should be modified in the presence of SO coupling. In this section, we consider the contact interaction with a momentum cutoff in a 3D and pure-2D uniform system of the SO-coupled spin-1/2 Fermi gas, as well as the Huang-Yang pseudo potential.

**A. Contact interaction in 3D system**

In this and the next subsection we give up the \( \vec{r} \)-representation, and use the Dirac symbol \( |\rangle \rangle \) defined in Sec. II.A to describe the state in the total Hilbert space \( H \). In a 3D system, the contact interaction \( \hat{U}_{\text{eff}} \) with a momentum cutoff can be expressed as an operator in \( H \): \[ \hat{U}_{\text{eff}} = \frac{U_0}{(2\pi)^3} \int d\vec{k} \langle |\vec{k}'| \rangle \langle \vec{k} | \rangle \langle S | \rangle \langle S | d\vec{k} \rangle \langle \vec{k}' | \rangle . \] Here \( k_c \) is a cut-off momentum and \( |\vec{k} \rangle = (2\pi)^{-3/2} \int d\vec{r} e^{i\vec{k} \cdot \vec{r}} |\rangle \rangle \). In these cases the second-quantized form \( \hat{U}_{\text{eff}} \) is given by \[ \hat{U}_{\text{eff}} = U_0 / \sqrt{\sum_{\vec{k},\vec{k}',\vec{K}} a_{\vec{k},\vec{K}} a^{\dagger}_{\vec{k}',\vec{K}}} \] where \( a_{\vec{p},\sigma}^{\dagger} \) and \( a_{\vec{p},\sigma} \) are the creation and annihilation operators for an atom with momentum \( \vec{p} \) and spin \( \sigma \). The summation \( \sum_{\vec{k},\vec{k}',\vec{K}} \) is under the condition max(|\vec{k}|,|\vec{k}'|) < k_c with \( k_c \) is a cut-off momentum.

The renormalization relation for this contact potential, i.e., the relationship between \( U_0 \) and \( k_c \), can be obtained from the condition \( \hat{U}_{\text{eff}} \) and the realistic inter-atomic interaction should lead to the same low-energy scattering amplitude. For the cases without SO-coupling, the standard calculation gives the well-known result

\[ \frac{1}{4\pi a_s} = \frac{1}{U_0} + \frac{1}{(2\pi)^3} \int_{k' < k_c} \hat{S} \frac{1}{k'^2} , \] with \( a_s \) the s-wave scattering length.

In the presence of SO coupling, the correct renormalization relation can be obtained by the same procedure. The effective scattering amplitude \( f_{\text{eff}}(t' \leftarrow t) \) given by \( \hat{U}_{\text{eff}} \) can be obtained from the Lippmann-Schwinger equation for the two-body \( T \)-operator \( \hat{T}_{\text{eff}}(\eta) \) with respect to \( \hat{U}_{\text{eff}} \):

\[ \hat{T}_{\text{eff}}(\eta) = \hat{U}_{\text{eff}} + \hat{U}_{\text{eff}} \hat{G}_0(\eta) \hat{T}_{\text{eff}}(\eta) , \] where the Green’s operator \( \hat{G}_0(\eta) \) is defined as

\[ \hat{G}_0(\eta) = \frac{1}{\eta + i\theta^+ - H_0} \] \[ = \sum_{\alpha} \int d\vec{k} \frac{|\vec{k} \rangle \langle \vec{k} | \rangle \langle \alpha, \vec{k} | \rangle \langle \alpha, \vec{k} | \rangle}{\eta + i\theta^+ - E_t} , \] where we have \( t = (\alpha, \vec{K}, \vec{k}) \) as before.

Using the Lippmann-Schwinger equation, we can obtain the equation for the \( T \)-matrix element:
where we have $t' = (\alpha', \tilde{K}', \tilde{E}')$ and $T_{\text{eff}}(\eta, t', t) = \langle \tilde{K}' | (\alpha', \tilde{K}' | T_{\text{eff}}(\eta) | \alpha, \tilde{K}) \rangle$. The notations $t''$ and $T_{\text{eff}}(\eta, t'', t)$ are defined similarly. From Eq. (39), we find that $T_{\text{eff}}(\eta, t', t)$ can be expressed as

$$ T_{\text{eff}}(\eta, t', t) = \frac{U_0}{(2\pi)^3} \langle \alpha', \tilde{K}' | S | \alpha, \tilde{K} \rangle + \frac{U_0}{(2\pi)^3} \langle \alpha', \tilde{K}' | S \rangle \left( \sum_{\alpha''} \int_{|\tilde{K}| < k_c} d\tilde{K}'' \langle S | \alpha'', \tilde{K}'' \rangle \frac{1}{\eta + i0^+ - E_{\tilde{K}''}} T_{\text{eff}}(\eta, t'', t) \right), $$

(39)

Here we have used Eq. (33). Comparing Eq. (39) with Eq. (40), we find that for the 3D contact potential with momentum cutoff, the form of the renormalization relation is not changed by the SO coupling. In the presence of SO coupling one only needs to replace the scattering length $a_s$ with $a_{\alpha}$. We mention that Eq. (28) for the bound-state energy $E_b$ can also be obtained from the contact potential $U_{\text{eff}}$ with renormalization relation (40).

### B. Contact potential in pure-2D system

Our above discussion can be directly generalized to pure-2D ultracold gases of spin-1/2 fermionic atoms with SO coupling. We assume the atoms are moving in the $x$-$y$ plane. Thus, the single-atom Hamiltonian is also given by Eq. (1), with $P = (P_x, P_y)$ the single-atom momentum in the $x$-$y$ plane. The Hamiltonian for the relative motion is then

$$ H^{(2D)} = \tilde{p}^2 + \lambda \tilde{c} \tilde{\rho} + B(\tilde{K}) + U_{2D}(\tilde{\rho}) \equiv H_0^{(2D)} + U_{2D}(\tilde{\rho}), $$

(47)

where $\tilde{K}$ is the two-atom total momentum, $\tilde{\rho} = (x, y)$ is the two-atom relative position in the $x$-$y$ plane, and $U_{2D}$ is the two-atom interaction potential in the 2D space, with effective range $\rho_s$. Here the operators $\tilde{c}$ and $B(\tilde{K})$ in the two-atom spin space are defined as in Sec. II, and SO-coupling intensity $\lambda$ is also assumed to be small enough so that the condition $\lambda << 1/\rho_s$ is satisfied.

Similar as in Sec. IIA, the incident state in the scattering, or the eigen-state of the Hamiltonian $H_0^{(2D)}$, can be described by the spinor wave function

$$ |\Psi_0^{(0)}(\tilde{r})\rangle = e^{i\tilde{K} \cdot \tilde{r}} 2^{-3/2} |\alpha, \tilde{K} \rangle - e^{-i\tilde{K} \cdot \tilde{r}} 2^{-3/2} P_{12} |\alpha, \tilde{K} \rangle $$

(48)

in the $\tilde{r}$-representation. Here the state $|\alpha, \tilde{K} \rangle$ for the two-atom spin is defined as in Sec. IIA, and we have $t = (\alpha, \tilde{K}, \tilde{E})$ as before. In Ref. [18], we have calculated the 2D scattering amplitude $f^{(2D)}(t' \leftarrow t)$ between $|\Psi^{(0)}_0(\tilde{r})\rangle$ and $|\Psi^{(0)}_0(\tilde{r})\rangle$ for the cases with Rashba SO-coupling. The method applied there can be directly used for the cases with arbitrary type of SO-coupling. The straightforward calculation yields

$$ f^{(2D)}(t' \leftarrow t) = -\frac{4\pi^3 \langle \Psi^{(0)}_0(0) | S | \Psi^{(0)}_0(0) \rangle}{\frac{\pi}{2} - \ln E_t^{1/2} - C - \ln \frac{\kappa_s}{2} - 2\pi F^{(2D)}(E_t)}, $$

(49)
where $C = 0.5772\ldots$ is the Euler $\Gamma$ number, $E_t$ is the eigen-value of $H_{0}^{(2D)}$, with respect to the eigen-state $|\Psi_t^{(0)}(\vec{r})\rangle$. In Eq. (49) the function $F^{(2D)}(\eta)$ is defined as

$$F^{(2D)}(\eta) = \frac{1}{(2\pi)^3} \sum_{\alpha''} \int d\vec{k}'' |S| \alpha'' \rangle \langle \alpha''| \frac{1}{\eta + i0^+ - E_{\alpha''} - \frac{1}{(\eta + i0^+ - \mathbb{E}^{(2D)}(\eta))^2}}, \quad (50)$$

with $t'' = (\alpha'', \mathbf{k}, \mathbf{k}'')$. The parameter $d_R$ in Eq. (49) can be determined by the following condition (see Appendix B of Ref. 48 where $d_R$ is denoted by $d$): in the region with $\rho < |\vec{r}| < 1/k$, the solution $|\psi_R(\vec{r})\rangle$ of equation

$$|\psi_T(\vec{r})\rangle \propto (|\psi_T(\vec{r})\rangle - \eta |\psi_T(\vec{r})\rangle) \quad (51)$$

satisfies $|\psi_T(\vec{r})\rangle \propto (|\psi_T(\vec{r})\rangle - \eta |\psi_T(\vec{r})\rangle)$. Here the rotation $T(\vec{r})$ is defined as $T(\vec{r}) = \exp(i\lambda c x/2) \exp(i\lambda c y/2)$.

Now we consider the 2D contact potential which takes the form

$$\tilde{U}_{\text{eff}}^{(2D)} = U_0 \frac{(2\pi)^3}{2} \int_{k' \leq k_c} |\tilde{\psi}|^2 \otimes |S| d\vec{k} d\vec{k}', \quad (52)$$

with $k_c$ is a cut-off momentum. Similar as in the 3D case, in the references where the area $S$ of the system is first assumed to be finite, the second-quantized form $\tilde{U}_{\text{eff}}^{(2D)}$ is given by $\tilde{U}_{\text{eff}}^{(2D)} = U_0^{(2D)} S^{-1} \sum_{\mathbf{k}, \mathbf{k}'} a_{\mathbf{k}'}^\dagger a_{\mathbf{k}} a_{\mathbf{k}'}^\dagger a_{\mathbf{k}} S_{\mathbf{k}'}^{(2D)} S_{\mathbf{k}}^{(2D)},$ with $a_{\mathbf{k}, \sigma}^\dagger, a_{\mathbf{k}, \sigma}$ and $\sum_{\mathbf{k}, \mathbf{k}'} S_{\mathbf{k}'}^{(2D)} S_{\mathbf{k}}^{(2D)}$ have similar definitions as in Sec. IV.B.

The renormalization relation for this contact potential can be obtained from the condition that $\tilde{U}_{\text{eff}}^{(2D)}$ and the realistic inter-atomic interaction should lead to the same low-energy scattering amplitude. In the absence of SO-coupling, the standard calculation gives

$$\frac{1}{U_0^{(2D)}} = -\frac{1}{(2\pi)^2} \int_{k' < k_c} d\vec{k}' - \frac{1}{\varepsilon + k'^2}, \quad (53)$$

where the physical parameter $\varepsilon > 0$ is the binding energy of the 2D two-atom bound state for the cases without SO coupling.

In the presence of SO coupling, the effective scattering amplitude $f_{\text{eff}}(t' \leftarrow t)$ given by $U_{\text{eff}}$ can be obtained with the method used in Sec. IV.A. The straightforward calculation gives

$$f_{\text{eff}}^{(2D)}(t' \leftarrow t) = \frac{4\pi^3}{\varepsilon - \ln E_t^{1/2} + \frac{2\pi}{U_0^{(2D)} E_t} + \ln k_c - 2\pi F^{(2D)}(E_t)}. \quad (54)$$

By requiring that $f_{\text{eff}}^{(2D)}(t' \leftarrow t) = f^{(2D)}(t' \leftarrow t)$ with $f^{(2D)}(t' \leftarrow t)$ given by Eq. (49), we obtain the following renormalization relation for systems with SO coupling in the limit $k_c \to \infty$:

$$\frac{1}{U_0^{(2D)}} = -\frac{1}{(2\pi)^2} \int_{k' < k_c} d\vec{k}' \frac{1}{\varepsilon_R + k'^2}. \quad (55)$$

with $\varepsilon_R = 4(2C)/d_{R}^{2}$. Comparing Eq. (58) with Eq. (55), we find that for the 2D contact potential with momentum cutoff, the form of the renormalization relation is not changed by the SO coupling. In the presence of SO coupling one only needs to replace $\varepsilon$ with $\varepsilon_R$.

C. Huang-Yang pseudo-potential

In the end of this section consider the Huang-Yang pseudo-potential $\Psi$ for the SO-coupled spin-1/2 fermi gas in a 3D system. In the $\vec{r}$-representation, the Huang-Yang pseudo-potential $\Psi$ is given by

$$U_{HY} = 4\pi a \delta(\vec{r}) \frac{\partial}{\partial r}(\vec{r}), \quad (56)$$

with $a$ the scattering length. Since $U_{HY}$ is a zero-range potential, the scattering state with respect to $U_{HY}$, i.e., the solution of the equation

$$[H_0 + U_{HY}] |\psi^{(+)}_t(\vec{r})\rangle = E_t |\psi^{(+)}_t(\vec{r})\rangle \quad (57)$$

with out-going boundary condition, should take the form

$$|\psi^{(+)}_t(\vec{r})\rangle = |\Psi^{(0)}_t(\vec{r})\rangle + B_r G_0 \left(E_t; \vec{r}, 0\right) |S\rangle \quad (58)$$

in the region with $r \equiv |\vec{r}| > 0$, and thus satisfy the Bethe-Peierls boundary condition. In the absence of SO-coupling, the Bethe-Peierls boundary condition is

$$\lim_{r \to 0} |\psi^{(+)}_t(\vec{r})\rangle \propto \left(\frac{1}{r} - \frac{1}{a}\right) |S\rangle. \quad (59)$$

According to this condition, the function $r |\psi^{(+)}_t(\vec{r})\rangle$ is continuous in the point $r = 0$. Therefore, the partial derivative $\partial/\partial r$ in $U_{HY}$ is well-defined for the function $r |\psi^{(+)}_t(\vec{r})\rangle$. Namely, the operation of the Huang-Yang pseudo-potential $U_{HY}$ on the wave function $|\psi^{(+)}_t(\vec{r})\rangle$ is well-defined.

Nevertheless, in the presence of the SO-coupling, as shown in Ref. 54, the Bethe-Peierls boundary condition is modified to

$$\lim_{r \to 0} |\psi^{(+)}_t(\vec{r})\rangle \propto \left(\frac{1}{r} - \frac{1}{a}\right) |S\rangle - i \frac{\lambda}{2} \vec{c} \cdot \left(\frac{\vec{r}}{r}\right) |S\rangle. \quad (60)$$

Due to the anisotropic term $-i \lambda \vec{c} \cdot \vec{r}/(2\pi)|S\rangle$, the function $r |\psi^{(+)}_t(\vec{r})\rangle$ is not continuous in the point $r = 0$. As a result, the partial derivative $\partial/\partial r$ in $U_{HY}$ is not well-defined for the function $r |\psi^{(+)}_t(\vec{r})\rangle$, and thus the operation of $U_{HY}$ on the wave function $|\psi^{(+)}_t(\vec{r})\rangle$ is no longer well-defined. Therefore, in the presence of SO-coupling, the Huang-Yang pseudo-potential is not consistent with the modified Bethe-Peierls boundary condition, and thus cannot be directly used in the theoretical calculations.
V. DISCUSSION

In this paper we derive the analytical expression of the scattering amplitude of two ultra-cold atoms with SO coupling. Our approach can also be used to calculate the wave function and the energy of two-body bound state. Moreover, we show that the SO coupling can induce inter-atomic scattering resonance. The influence of such a resonance in the many-body physics of the SO-coupled ultra-cold gases remains to be explored. With the expression of scattering amplitude, we further prove that the renormalizations relations of the 3D and 2D contact potentials with momentum cutoff are not changed. Nevertheless, in the presence of SO coupling the physical parameters in the renormalization relation should be replaced by the ones which are related to the SO coupling. It is pointed out that, our result provides a solid basis for some previous theoretical works (e.g., Refs. 22, 23, 44) where the renormalizations relations with these forms are used for the SO-coupled gases without proof. We also show that in the presence of the SO-coupling, the Huang-Yang pseudo-potential is no longer consistent with the modified Bethe-Peierls boundary condition, and thus cannot be directly used in the theoretical calculations.

Acknowledgments

We thank H. Zhai, X. Cui, H. Duan and L. You for useful discussions. PZ would also like to thank the NCET Program for support.

Appendix A: Behavior of scattering wave function

In this Appendix we give the explicit definition of the effective range \( r_s \) for the potential \( U(\vec{r}) \), and prove Eqs. (A1) for the behavior of the scattering state \( |\Psi_{1}^{(+)}(\vec{r})\rangle \) and bound state \( |\Psi_{0}(\vec{r})\rangle \) in the region \( r \gg r_s \). Although this problem has been discussed by us in Refs. 52 and 53, the treatment there is not fully rigorous. Here we provide a more explicit analysis.

We first consider the case of spin-1/2 atoms. According to the scattering theory, \( |\Psi_{1}^{(+)}(\vec{r})\rangle \) is determined by the Lippman-Schwinger equation

\[
|\Psi_{1}^{(+)}(\vec{r})\rangle = |\Psi_{1}^{(0)}(\vec{r})\rangle + \int d\vec{r}' G_{0}(E_{1}, \vec{r}, \vec{r}') U(\vec{r}') |\Psi_{1}^{(+)}(\vec{r}')\rangle,
\]

(A1)

with the Green’s function \( G_{0} \) defined in Eq. (10). Here we assume the potential \( U(\vec{r}) \) is negligible when the inter-atomic distance is larger than a characteristic length \( r_0 \), i.e., \( U(\vec{r}) \approx 0 \) in the region \( r \gg r_0 \). Thus, the integration in Eq. (A1) is only effective in the region \( r' \ll r_0 \).

If the momentum \( k \) is low enough so that \( k < 1/r_0 \), when \( r \rightarrow \infty \) and \( r' \ll r_0 \), the function \( G_{0}(E, \vec{r}, \vec{r}') \) varies very slowly with respect to \( \vec{r}' \) and we have \( G_{0}(E, \vec{r}, \vec{r}') \approx G_{0}(E, \vec{r}, 0) \). Therefore, in the limit \( r \rightarrow \infty \), the solution of Eq. (A1) takes the form

\[
|\Psi_{1}^{(+)}(\vec{r})\rangle \approx |\Psi_{1}^{(0)}(\vec{r})\rangle + G_{0}(E_{1}, \vec{r}, 0)|\phi\rangle,
\]

(A2)

where the spin state \( |\phi\rangle \) is related to \( |\Psi_{1}^{(+)}(\vec{r})\rangle \) via the equation

\[
|\phi\rangle = \int d\vec{r}' U(\vec{r}') |\Psi_{1}^{(+)}(\vec{r}')\rangle.
\]

(A3)

Furthermore, due to the facts \( P_{12}|\Psi_{1}^{(+)}(-\vec{r})\rangle = -|\Psi_{1}^{(+)}(\vec{r})\rangle \) and \( P_{12}U(-\vec{r})P_{12} = U(\vec{r}) \) with \( P_{12} \) the permutation operator of the spin of the two atoms, one finds that \( P_{12}(U(-\vec{r})|\Psi_{1}^{(+)}(-\vec{r})\rangle) = -U(\vec{r}) |\Psi_{1}^{(+)}(\vec{r})\rangle \). This result yields

\[
|\phi\rangle = \int d\vec{r}' U(\vec{r}') |\Psi_{1}^{(+)}(\vec{r}')\rangle = B_{1}|S\rangle,
\]

(A4)

with \( B_{1} \) a constant number. Therefore, when the inter-atomic distance \( r \) is large enough, we have

\[
|\Psi_{1}^{(+)}(\vec{r})\rangle \approx |\Psi_{1}^{(0)}(\vec{r})\rangle + B_{1}G_{0}(E_{1}, \vec{r}, 0)|S\rangle.
\]

(A5)

A direct result is that there exists a characteristic length \( r_s \) and Eq. (A5) is applicable in the region \( r \gg r_s \). It is apparent that we have \( r_s \gg r_0 \). In this paper we define such a characteristic length as the effective range of the potential \( U(\vec{r}) \). Therefore, Eqs. (A3), (A5) or Eqs. (8) are naturally satisfied when \( r \gg r_s \).

When \( U(\vec{r}) \) is spherical, in the low-energy case one only needs to take into account the s-wave scattering. The straightforward calculation shows that, as a result of the s-wave approximation, we have \( r_s = r_0 \). When \( U(\vec{r}) \) is anisotropic, the effective range \( r_s \) is larger than \( r_0 \). In our current paper and Ref. 52, we assume the kinetic energy of atomic relative motion is low enough so that the effective ranges of \( U(\vec{r}) \) and the “rotated potential”

\[
U_{R}(\vec{r}) = e^{i\lambda c_{x}/2}e^{i\lambda c_{y}/2}U(\vec{r})e^{-i\lambda c_{x}/2}e^{-i\lambda c_{y}/2}e^{-i\lambda c_{z}/2}
\]

(A6)

is much smaller than \( 1/k \). This condition can be satisfied in the dilute gases. In particular, in the systems where the condition \( r_0 << 1/k \) is satisfied and the anisotropy of \( U(\vec{r}) \) and \( U_{R}(\vec{r}) \) is small enough so that the relevant effective ranges of \( U \) and \( U_{R} \) are in the same order of magnitude with \( r_0 \).

Our above analysis can be directly generalized to the general cases of atoms with arbitrary spin. In that case the scattering state \( |\Psi_{1}^{(+)}(\vec{r})\rangle \) takes the form in Eq. (A2).
in the whole region with \( r \gtrsim r_\ast \), and the \( \vec{r} \)-independent state \(|\phi\rangle\) is also related to \(|\Psi'_1(\vec{r})\rangle\) via Eq. (A3). Nevertheless, now \(|\phi\rangle\) is not unique. It can be different for different incident states \(|\Psi_1^0(\vec{r})\rangle\). Then we can obtain the result in Eqs. (24)-(25).

Now we consider the low-energy bound state of two SO-coupled atoms. It is clear that the wave function \(|\Psi_b(\vec{r})\rangle\) of the bound state is given by the equation

\[
|\Psi_b(\vec{r})\rangle = N_b \int d\vec{r}' G_0(E_b, \vec{r}, \vec{r}') U(\vec{r}') |\Psi_b(\vec{r}')\rangle
\]

with \( E_b \) the energy of the bound state and \( N_b \) the normalization factor. With similar discussion as above, when \(|E_{\text{binding}}| < 1/r_\ast^2\) we have

\[
|\Psi_b(\vec{r})\rangle \approx N_b G_0(E_b, \vec{r}, 0) |\phi_b\rangle
\]

in the region \( r > r_\ast \). That is the result in Eq. (27). In this paper we assume the condition \(|E_{\text{binding}}| < 1/r_\ast^2\) is satisfied.

### Appendix B: The short-range behaviors of free Green’s function

In this Appendix we prove Eq. (12) for the short-range behaviors of \( G_0(E_t, \vec{r}, 0) \) with the following three steps. First, with the fact

\[
\delta(\vec{r} - \vec{r}') = \int d\vec{r}'' e^{i\vec{r}'' \cdot (\vec{r} - \vec{r}')/(2\pi)} \left( \sum_{\alpha''} |\alpha'', \vec{k}''\rangle \langle \alpha'', \vec{k}''| \right),
\]

it is easy to show that

\[
G_0(\eta, \vec{r}, 0) = \sum_\alpha \int d\vec{r}'' e^{i\vec{r}'' \cdot \vec{r}} |\alpha'', \vec{k}''\rangle \langle \alpha'', \vec{k}''| \frac{1}{\eta + i0^+ - E_{\alpha''}}
\]

with \( t'' = (\alpha'', \vec{k}, \vec{k}'') \). Eq. (B2) and the completeness relationship \( \sum_{\alpha''} |\alpha'', \vec{k}''\rangle \langle \alpha'', \vec{k}''| = 1 \) lead to the result

\[
G_0(\eta, \vec{r}, 0) = \int d\vec{r}\int d\vec{r}'' e^{i\vec{r}'' \cdot \vec{r}} \frac{1}{\eta + i0^+ - k''^2}
\]

with the operator \( \mathcal{F}(\eta, \vec{k}'') \) defined in Eq. (14). Similarly as in Sec. II.A, the fact \( \lim_{|\vec{k}| \to \infty} h_0(\vec{k}) = \lambda\vec{c} \cdot \vec{k} \) gives

\[
\lim_{k'' \to \infty} \mathcal{F}(\eta, \vec{k}'') e^{i\vec{r}'' \cdot \vec{r}} + \mathcal{F}(\eta, -\vec{k}'') e^{-i\vec{r}'' \cdot \vec{r}} = \frac{1}{\lambda\vec{c} \cdot \vec{k}'' + O(1/k'^2)}
\]

Therefore, using \( \int d\vec{k}'' = \int \frac{d^3k''}{(2\pi)^3} \int d\Omega_{\vec{k}''} \) with \( \Omega_{\vec{k}''} \) the solid angle of \( \vec{k}'' \) it is easy to prove that the integration in the right-hand side of Eq. (B3) does not diverge. On the other hand, we also have

\[
\int d\vec{k}'' e^{i\vec{k}'' \cdot \vec{r}} \frac{1}{\eta + i0^+ - k''^2} = -\frac{e^{i\vec{r} \cdot \vec{r}}}{4\pi r}
\]

with \( \arg\eta \in (-\pi, \pi] \). Due to these facts, we have

\[
\lim_{r \to 0} G_0(\eta, \vec{r}, 0) = -\frac{1}{4\pi r} + O(r^0). \tag{B5}
\]

Second, as in Ref. [54], we introduce a unitary transformation \( \mathcal{R}(\vec{r}) \) as

\[
\mathcal{R}(\vec{r}) = e^{i\lambda c_z z/2} e^{i\lambda c_y y/2} e^{i\lambda c_z z/2}, \tag{B6}
\]

with \( \vec{c} \equiv (c_x, c_y, c_z) \). The rotated free Hamiltonian \( H_{\text{OR}} = \mathcal{R}(\vec{r}) H_0 \mathcal{R}(\vec{r})^\dagger \) can be calculated as

\[
H_{\text{OR}} = p^2 - 2\lambda d(\vec{r}) \cdot \vec{p} + W(\vec{r}) \tag{B7}
\]

with operators \( d \equiv (d_x, d_y, d_z) \) and \( W \) given by

\[
d_x(\lambda \vec{r}) = 0; \tag{B8}
\]

\[
d_y(\lambda \vec{r}) = c_z e^{-i\lambda c_z z/2} - \mathcal{R}(\vec{r}) \frac{c_y}{2} \mathcal{R}(\vec{r})^\dagger; \tag{B9}
\]

\[
d_z(\lambda \vec{r}) = \frac{c_x}{2} - \mathcal{R}(\vec{r}) \frac{c_y}{2} \mathcal{R}(\vec{r})^\dagger, \tag{B10}
\]

and

\[
W(\vec{r}) = i\lambda \left[ \nabla \cdot d(\lambda \vec{r}) + \mathcal{R}(\vec{r}) \mathcal{B}(\vec{k}) \mathcal{R}(\vec{r})^\dagger \right] + 
\lambda^2 \left[ |d(\lambda \vec{r})|^2 - \mathcal{R}(\vec{r}) |\mathcal{G}|^2 4 \mathcal{R}(\vec{r})^\dagger \right]. \tag{B11}
\]

Now we define the rotated Green’s function \( G_{\text{OR}}(\eta, \vec{r}, 0) \) as the Green’s function with respect to \( H_{\text{OR}} \), i.e.,

\[
G_{\text{OR}}(\eta, \vec{r}, 0) = \frac{1}{\eta + i0^+ - H_{\text{OR}}} \delta(\vec{r}). \tag{B12}
\]

According to Eqs. (B8)-(B10), we have \( d(\lambda \vec{r}) = O(\lambda r) \). Namely, the SO-coupling term in \( H_0 \) vanishes in the limit \( r \to 0 \). Due to this fact, in such a limit \( G_{\text{OR}}(\eta, \vec{r}, 0) \) has the same behavior with the Green’s function \( G_W(\eta, \vec{r}, 0) \), which is defined as

\[
G_W(\eta, \vec{r}, 0) = \frac{1}{\eta + i0^+ - |\vec{p}|^2 + W(0)} \delta(\vec{r})
\]

\[
= - \sum_n |W_n\rangle \langle W_n| \frac{\delta(\vec{r})}{4\pi}, \tag{B13}
\]

with \( W_n \) and \( |W_n\rangle \) the \( n \)-th eigen-value and eigenstate of the operator \( W(0) \), respectively. Since \( \lim_{r \to 0} G_W(\eta, \vec{r}, 0) \) is the sum of \(-1/(4\pi r)\) and a \( \vec{r} \)-independent operator, we have

\[
\lim_{r \to 0} G_{\text{OR}}(\eta, \vec{r}, 0) = -\frac{1}{4\pi r} + G_0(\eta), \tag{B14}
\]

with \( G_0(\eta) \) a \( \vec{r} \)-independent operator in the space of two-atom spin.

As in Ref. [54], the result in Eq. (B14) can be proved as follows. According to the definition of \( G_{\text{OR}} \), it is obvious that

\[
G_0(\eta, \vec{r}, 0) = \mathcal{R}(\vec{r}) G_0(\eta, \vec{r}, 0). \tag{B15}
\]
Due to this relation and Eq. (B15), $G_{OR}(\eta, \vec{r}, 0)$ can be expressed as the sum of $-1/(4\pi r)$ and another term which converges in the limit $r \to 0$. Then we have

$$G_{OR}(\eta, \vec{r}, 0) = -\frac{1}{4\pi} + \sum_{n=0}^{\infty} \sum_{l=1}^{\infty} \sum_{n=0}^{L_l} r^n G_n^l(\eta)$$

with $(r, \theta, \phi)$ the spherical coordinate. Here $Y_{l,m}(\theta, \phi)$ are the spherical harmonic functions, $G_n^l(\eta)$ and $J_{l,m,n}(\eta)$ are $\vec{r}$-independent operators in the space of two-atom spin.

In the region $r > 0$, the Green's function $G_{OR}(\eta, \vec{r}, 0)$ satisfies

$$\left[\vec{p}^2 - 2\lambda \vec{d}(\lambda \vec{r}) \cdot \vec{p} + W(\vec{r})\right] G_{OR}(\eta, \vec{r}, 0) = \eta G_{OR}(\eta, \vec{r}, 0).$$

(B17)

Substituting Eq. (B16) into Eq. (B17) and comparing the coefficients of the term $r^{-2}$ in both sides, we find that because $d(\lambda r) = O(\lambda r)$, one has $J_{l,m,n}(\eta) = 0$. Therefore, in the limit $r \to 0$, $G_{OR}(\eta, \vec{r}, 0)$ behaves as in Eq. (B17).

Third, using Eq. (B15) and Eq. (B14), we finally have

$$\lim_{r \to 0} G_{O}(\eta, \vec{r}, 0) = -\frac{1}{4\pi} + i \frac{\lambda}{8\pi} \cdot \vec{r} + G_0(\eta).$$

(B18)

Now we derive the $\vec{r}$-independent operator $G_0(\eta)$ in the space of two-atom spin. Therefore, we have

$$G_0(\eta) = \lim_{r \to 0} \frac{1}{2} \left[G_0(\eta, \vec{r}, 0) + G_0(\eta, -\vec{r}, 0) + \frac{1}{2\pi r}\right].$$

(B19)

Using the Eqs. (B13) and (B14) and the fact

$$\lim_{r \to 0} \left[\int d\vec{k} f(\vec{k}) e^{-i\vec{k} \cdot \vec{r}} + \int d\vec{k} f(\vec{k}) e^{-i\vec{k} \cdot \vec{r}}\right] = 2 \int d\vec{k} f(\vec{k}),$$

(B20)

we find that

$$G_0(\eta) = -\frac{i \eta^{1/2}}{4\pi} + F(\eta),$$

(B21)

with the operator $F(\eta)$ defined in Eq. (13).

In the short-range region, the behavior of $G_0(\eta; \vec{r}, 0)$ is given by $\lim_{r \to 0} G_0(\eta, \vec{r}, 0)$. Thus, substituting Eq. (B21) into Eq. (B18), we obtain

$$G_0(\eta; \vec{r}, 0) \approx -\frac{1}{4\pi} \left(1 + \frac{r}{\lambda}\right) + F(\eta) + \frac{i \lambda}{8\pi} \cdot \vec{r}.$$  

(B22)

That is the result in Eq. (12).
