**Keywords:** *Staphylococcus aureus*  
Enterotoxin  
Raw milk  
PCR

### Abstract

**Background:** *Staphylococcus aureus* is one of the major causes of food poisoning. Since milk is a nutritious source of proteins and vitamins, it could provide the optimal conditions for the growth of several bacterial pathogens, such as *S. aureus*. The present study aimed to assess the frequency of *Staphylococcus aureus* classical enterotoxin genes in raw milk samples in Zanjan, Iran.

**Methods:** In total, 82 bovine, unpasteurized milk samples were collected from the dairy farms in various rural areas in Zanjan, Iran. The isolation and identification of *S. aureus* were performed using the Baird-Parker agar, routine biochemical tests, and polymerase chain reaction (PCR) targeting the *S. aureus*-specific femA gene. In addition, staphylococcal enterotoxin genes (e.g., *sea*, *seb*, *sec*, *sed*, and *see*) were assessed using PCR.

**Results:** Following the appearance of yellow colonies with yellow zones on Mannitol salt agar, 21 *S. aureus* isolates (25.6%) were detected. In total, 80.9% of the isolates were positive for the presence of SE genes, and the most frequent SE gene was *sea* (88.2%), followed by *see* (58.8%), and *seb* (52.9%). Furthermore, 76.5% of the isolates had two or more SE genes simultaneously.

**Conclusion:** According to the results, the presence of enterotoxigenic *S. aureus* in the studied raw milk samples confirmed the possible risk posed on the public health. Therefore, it is recommended that the quality of dairy product quality programs be optimized in order to intensify the sanitary inspection of these products.

### 1. Introduction

*Staphylococcus aureus* is a gram-positive, non-spore-forming, immotile coccus belonging to the family Micrococccaeae, which is considered to be a leading cause of bacterial food poisoning outbreaks [1-3]. Staphylococcal food poisoning (SFP) is caused by the consumption of contaminated foods containing enterotoxins. Approximately 20-30% of human populations are consistent carriers of this bacterium, while 60% are the transient carriers of *S. aureus*. Therefore, the insufficient pasteurization and decontamination of food products or their contamination during preparation, processing, and distribution by the carriers of *S. aureus* are the common risk factors for the outbreaks of staphylococcal food poisoning [3-6].

Some of the food products that are often involved in the transmission of staphylococcal poisoning include meat and its products, poultry and egg products, milk and dairy products, salads, bakery products (especially cream-filled pastries and cakes), and sandwich fillings [7-11]. The most common symptoms of staphylococcal food poisoning are nausea and vomiting, diarrhea, and abdominal cramps, which occur within 2-6 hours after the consumption of enterotoxin-containing foods. Occasionally, SFP may be more severe or even fatal, especially in infants, the elderly or immunocompromised patients [11, 12].

**How to cite:** Haghi F, Daneshamooz Sh, Parsadanians A, Zeighami H. Frequency of *Staphylococcus aureus* Classical Enterotoxins Genes in Raw Milk Samples from Zanjan, Iran. *J Hum Environ Health Promot.* 2019; 5(1): 32-5.
Staphylococcal enterotoxins (e.g., SEs, SEA-SEE, SEG-SEI, and SER-SET) and staphylococcal enterotoxin-like toxins (e.g., SELs) have been reported to be involved in food poisoning; such examples are SEIK-SEIQ and SEIU-SEIX. SEs and SELs are single-chain proteins with the size range of 22-29 KDa and encoded by various genetic elements, such as plasmids, bacteriophages, pathogenicity islands, vSA genomic islands, and staphylococcal cassette chromosome [12-15]. Extremely low amounts of SE (approximately 20 ng·1 μl) in food products are required to develop food poisoning [7, 16, 17]. Due to the stability of SELs at high temperatures and low pH, these toxins are not completely destroyed by the mild cooking or digestion of food in the stomach [18], thereby posing significant risks to the health of the consumers after using unpasteurized milk. During 2011-2014, 4,211 foodborne disease outbreaks were reported in China, in which S. aureus was recognized as one of the most prominent cause of the disease in 3,269 of the cases [7, 19].

The consumption of homemade dairy products, such as raw milk, is associated with severe public health hazards [12]. Despite the governmental surveillance of milk pasteurization and sanitation in dairy processing plants for several years, the direct sale of unpasteurized milk and dairy products is rather common in many regions in Iran, such as Zanjan province. Therefore, it is essential to obtain adequate data on the microbial risk factors associated with the production of raw milk. Risk assessment and microbial monitoring also play a pivotal role in the quality assurance of milk and its products [12]. To the best of our knowledge, data is scarce regarding the frequency of S. aureus and enterotoxin genes in raw milk samples in Iran. The present study aimed to investigate the frequency of S. aureus and classical enterotoxin genes in the bacterial strains isolated from the raw milk samples collected from the dairy herds in Zanjan, Iran. This is the first report on the frequency of enterotoxigenic S. aureus in raw milk samples in Zanjan, Iran.

2. Materials and Methods

2.1. Collection of Milk Samples

During March-June 2017, 82 bovine, unpasteurized milk samples (one sample per animal) were collected from the traditional dairy farms in various rural areas in Zanjan, Iran. The animals from which the milk samples were obtained for the study were clinically healthy, and the milk samples showed physicochemical consistency in terms of color, pH, and density. The milk samples were collected in 50-milliliter sterile centrifuge tubes (SPL Life Sciences, Gyeonggi-do, Korea) and immediately transferred to the laboratory of food microbiology in a chilled box for further analysis within one hour.

2.2. Reference Strains

The reference strains used as the positive controls in the present study included S. aureus ATCC 13565 (SEA), S. aureus ATCC 14458 (SEB), S. aureus ATCC 19095 (SEC), S. aureus ATCC 23235 (SED), and S. aureus ATCC 27664 (SEE).

2.3. Isolation and Identification of S. aureus

The milk samples were centrifuged at 5,000 rpm for five minutes, and bacterial pellets were streaked onto the Baird-Parker agar (Merck, Darmstadt, Germany) and incubated in aerobic conditions at the temperature of 37°C for 24 hours. Afterwards, the grey-black colonies were sub-cultured onto the Mannitol salt agar (Merck, Darmstadt, Germany) and incubated at the temperature of 37°C for 24 hours. In addition, the suspected S. aureus colonies were identified using routine biochemical tests, including gram staining, catalase, coagulase, oxidase, lipase, DNase tests, and PCR targeting the S. aureus-specific femA gene (specific to the S. aureus species. The primer sequence in this experiment is presented in Table 1 [20].

2.4. Genomic DNA Extraction

A colony of S. aureus was collected from the nutrient agar and inoculated into two milliliters of Luria Bertani broth (Merck, Darmstadt, Germany) until achieving the exponential phase with 2 McFarland turbidity (6×10 8 CFU/ml) and shaking at 120 rpm and the temperature of 37°C. The extraction of genomic DNA was performed in accordance with the protocol of GeneAll Exgene Genomic DNA Micro (GeneAll Biotechnology, Seoul, Korea).

2.5. Detection of sea and see Enterotoxins Using PCR

Staphylococcal enterotoxin genes (sea, seb, sec, sed, and see) were assessed using the primers shown in Table 1. Simplex PCR was performed using DreamTaq PCR Master Mix (Ampliqon, Denmark), which contained Taq polymerase, dNTPs, MgCl2, and an appropriate buffer. In addition, each PCR tube contained 25 microliters of the reaction mixture, which was composed of 12.5 microliters of the master mix, one microliter of each forward and reverse primer solution (final concentration: 200 nM), one microliter of DNA (concentration: 100 ng/μl), and nuclease-free water to achieve the final volume.

At this stage, PCR was performed using the Gene Atlas 322 system (ASTEC) with the same cycling conditions for the sea-see genes. Amplification involved initial denaturation at the temperature of 94°C for five minutes, followed by 30 cycles of denaturation (94°C, 1.5 minutes), annealing (55°C, 1.5 minutes), extension (72°C, 1.5 minutes), and final extension (72°C, 8 minutes). Following that, the amplified DNA was separated via submarine gel electrophoresis on 1.5% agarose, stained with ethidium bromide, and visualized using a UV transilluminator.

Table 1: Primers used in this study

| Target | Primer sequence (5′→3′) | Ampli sequence (bp) | Ref. |
|--------|-------------------------|---------------------|------|
| femA   | AAAAAGGCAATACAAAGAC     | 132                 | [20] |
| sea    | CTTTGGAAAACCTTAAAGG     | 127                 | [30] |
| seb    | TCCTCATCAACCTCAGAACC    | 477                 | [30] |
| sec    | CTTAAGAATACATGAAAGCTAG  | 271                 | [30] |
| sed    | CTAGTTGTGTAATCTTCCTTAAAAGC | 319                | [30] |
| see    | CAGCTTATATAGATACATGACTC | 178                 | [30] |
3. Results and Discussion

Food safety is considered to be a major global health concern with international trade and public health implications. S. aureus is the most common cause of food poisoning and a major public health concern in developing countries [21, 22]. Staphylococcal food poisoning due to the consumption of raw milk has been reported in various studies [20, 22-24]. In the current research, 82 bovine raw milk samples were assessed in terms of the presence of S. aureus. Following the appearance of yellow colonies with yellow zones on the Mannitol salt agar, 21 S. aureus isolates (25.6 %) were detected. Furthermore, the biochemical tests and molecular analysis of the femA gene in the coagulase-positive staphylococci confirmed the presence of these isolates. Similar to our findings, Rahbar Saadat et al. (2014) detected S. aureus in 27% of milk and cheese samples [25].

To the best of our knowledge, there is inadequate data regarding the frequency of S. aureus and enterotoxin genes in the raw milk samples in Iran. This is first report on the frequency of enterotoxigenic S. aureus in the raw milk samples in Zanjan province. Most of the studies in this regard have been focused on enterotoxigenic S. aureus in specific geographical areas, while a nationwide surveillance system has not been established yet.

According to the study by Hassani et al. (2014) in Iran, 43% of dairy samples were contaminated with S. aureus, with 22% of the bacterium detected in the milk samples and 18% detected in the cheese samples [23]. Inconsistent with the results of the present study, higher frequency of S. aureus was reported in domestic dairy products in a previous study conducted in Iran. According to the mentioned study, 32% of the dairy products were contaminated with S. aureus (cream: 18%, cheese: 10%, milk: 4%) [24]. Although the health regulations in Iran have not established any limits for the permitted level of S. aureus in milk, it is known that the enterotoxins produced by these isolates could reach sufficient levels to cause food poisoning symptoms of the S. aureus concentrations exceeded 105 CFU/ml [26]. The frequency of raw milk contamination with S. aureus has been reported to be lower (7.3%) in São Paulo state, Brazil (2010). According to the results of the mentioned study, S. aureus strains were detected in 14 cow milk samples (6.7%) and four bulk tank milk samples (10.8%) [27]. The variation in the frequency of S. aureus in dairy products may be due to the differences in the geographical region, number of samples, season of sampling, post-harvest practices, the hygienic standards that are applied during the handling, transport, and storage of dairy products, and methods used for the isolation and identification of S. aureus [11].

According to the findings of the current research, 80.9% of the isolates (n = 17/21) were positive for the presence of at least one or more SE genes. The most prevalent SE gene among the isolates detected in the raw milk samples was sea (n = 15/17, 88.2%), followed by see (n = 10/17, 58.8%) and seb (n = 9/17, 52.9%). Moreover, the frequency of the sec and sed genes was estimated at 23.5% and 17.6%, respectively. Consistent with the results of the present study, SEA has been reported to be the most common cause of food poisoning in Korea and Japan [28].

The previous studies in this regard have also indicated that sea and sed are the most common enterotoxin genes in the staphylococci isolated from food products [29]. However, the frequency of sed (17.6%) was observed to be lower in the isolates of the raw milk samples in the current research. In contrast, seb has been observed to be a prevalent gene in patients with food poisoning in Taiwan and Japan, while sec has been reported to be a major SE gene in the isolates found in the bulk milk samples in Switzerland and Korea [28].

In current research, multiple SE genes were present with various combinations in the studied isolates (Table 2). Among 17 S. aureus isolates carrying enterotoxin genes, 13 cases (76.5%) contained two or more SE genes simultaneously. In this regard, the most frequent combination of SE genes was sea+see (23.5%), followed by sea+seb+see (17.6%). Furthermore, one isolate (5.8%) carried the sea, seb, sec, and see genes simultaneously.

One of the limitations of the present study was the small sample size. Furthermore, due to the lack of funding, it was not possible to investigate the frequency of S. aureus in other dairy products, such as cheese, cream, butter, yoghurt, and Kashk.

**Table 2:** SE combinations among 17 S. aureus isolates carrying enterotoxin genes.

| SE combinations     | No. (%) of isolates |
|---------------------|---------------------|
| sea+sed             | 1 (5.8)             |
| sea+seb             | 2 (11.7)            |
| sea+see             | 4 (23.5)            |
| sec+sed             | 1 (5.8)             |
| sec+seb+see         | 3 (17.6)            |
| sec+sed+see         | 1 (5.8)             |
| sea+seb+sec+see     | 1 (5.8)             |

4. Conclusion

Raw milk is widely available in the marketplace in Zanjan, Iran. Therefore, it is essential to collect adequate data regarding the microbial risk factors and health hazards associated with the production of raw milk. Critical control point management programs should be developed for milk production farms individually based on risk assessment and total quality management. Moreover, critical control point principles (e.g., pasteurization and sanitary treatment of milk) are essential to obtaining safe and healthy milk for processing and consumption.
