Abstract
The goal of this paper is to investigate the family of Blasche products $B_a(z) = z^{-a} \frac{z - a}{1 - az}$, which is a rational family of perturbations of the doubling map. We focus on the tongue-like sets which appear in its parameter plane. We first study their basic topological properties and afterwards we investigate how bifurcations take place in a neighborhood of their tips. Finally we see how the fixed tongue extends beyond its natural domain of definition.

Keywords: holomorphic dynamics, Blaschke products, circle maps, tongues

1. Introduction

Given a rational map $f : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$, where $\hat{\mathbb{C}} = \mathbb{C} \cup \{\infty\}$ denotes the Riemann sphere, we consider the dynamical system given by the iterates of $f$. The Riemann sphere splits into two totally $f$-invariant subsets: the Fatou set $\mathcal{F}(f)$, which is defined to be the set of points $z \in \hat{\mathbb{C}}$ where the family $\{f^n, n \in \mathbb{N}\}$ is normal in some neighborhood of $z$, and its complement, the Julia set $\mathcal{J}(f)$. The dynamics of the points in $\mathcal{F}(f)$ are stable in the sense of normality or equicontinuity, whereas the dynamics in $\mathcal{J}(f)$ present chaotic behavior. The Fatou set is open and its connected components, called Fatou components, are mapped under $f$ among themselves.
All Fatou components of a rational map are either periodic or preperiodic (see [Su185]). By means of the classification theorem (see [Mi106]), any periodic Fatou component of a rational map is either the basin of attraction of an attracting or parabolic cycle, or a simply connected rotation domain (a Siegel disk), or a doubly connected rotation domain (a Herman ring). Moreover, any such component is somehow related to a critical point, i.e. a point \( z \in \hat{\mathbb{C}} \) such that \( f'(z) = 0 \). Indeed, the basin of attraction of an attracting or parabolic cycle contains, at least, a critical point whereas Siegel disks and Herman rings have critical orbits (orbits of critical points) accumulating on their boundaries.

The aim of this paper is to study the bifurcations that occur in the parameter plane of the degree 4 Blaschke products given by

\[
B_a(z) = z^4 \frac{z - a}{1 - \overline{a} z},
\]

where \( a, z \in \mathbb{C} \). As we shall explain below, this family is interesting for several reasons, being the rational analogue of the well known double standard family of perturbations of the doubling map of the unit circle. Indeed, as all finite Blaschke products, the maps \( B_a \) leave the unit circle \( \mathbb{S} \) invariant, i.e. \( B_a(\mathbb{S}) = \mathbb{S} \). Moreover, they are rational perturbations of the doubling map of the circle \( B_0(z) = z^2 \) (equivalently given by \( \theta \rightarrow 2\theta \) (mod 1)). Indeed, if \( a = re^{\pi i \theta} \) with \( \alpha \in \mathbb{R} \), the rational maps \( B_a \) converge uniformly over compact subsets of the punctured plane \( \mathbb{C}^* \) to \( e^{\pi i \alpha} z^2 \) as \( r \) tends to \( \infty \). In fact, if \(|a| \geq 2\), the circle maps \( B_{|a|} \) are degree two coverings of the unit circle and hence they are semiconjugate to the doubling map (see [MR07]).

For all values of \( a \in \mathbb{C} \), the points \( z = 0 \) and \( z = \infty \) are superattracting fixed points of local degree 3 (see [CFG15]). We denote by \( A_d(0) \) and \( A_d(\infty) \) their basins of attraction and by \( A_d'(0) \) and \( A_d'(\infty) \) their immediate basins of attraction, i.e. the connected components of \( A_d(0) \) and \( A_d(\infty) \) which contain \( z = 0 \) and \( z = \infty \), respectively. We shall drop the dependence on \( a \) whenever it is clear from the context. If \(|a| \leq 1\), \( B_a(\mathbb{D}) = \mathbb{D} \) and the basins of attraction \( A(0) = \mathbb{D} \) and \( A(\infty) = \mathbb{C} \setminus \mathbb{D} \) are the only Fatou components, separated by the Julia set which is necessarily \( \mathbb{S} \). But for every other parameter, there is a preimage of infinity \( z_\infty \in \mathbb{D} \) and the two free critical points \( c_\pm \) (distinct unless \(|a| = 2\)) may lead to the existence of stable components different from \( A(0) \) and \( A(\infty) \). If \(|a| \geq 2\), even if there are two free critical points, the Blaschke family is essentially unicritical due to the symmetry with respect to \( \mathbb{S} \) which, in this case, ties the two critical orbits together in a certain sense.

Given a family \( f_a \) of analytic orientation preserving homeomorphisms of the unit circle, where \( a \in \Delta \) and \( \Delta \subset \mathbb{C} \) or \( \Delta \subset \mathbb{R}^2 \), one can assign a rotation number to each of its members which gives the average asymptotic rate of rotation of points in the circle. The level sets of the rotation number are known as tongues or Arnold tongues, since they were introduced by Arnold [Arn61] for the standard family of perturbations of the rigid rotation

\[
\theta \rightarrow \theta + \alpha + (\beta/2\pi) \sin(2\pi \theta) \pmod{1}
\]

where \( 0 \leq \theta < 1 \), \( 0 \leq \alpha \leq 1 \) and \( 0 \leq \beta \leq 1 \). Tongues have been studied by many authors, both for the Arnold standard maps (see e.g. [Boy86], [WBJ91], [EKT95] or [dILL11]) and for other families of homeomorphisms of the unit circle such as the degree 3 Blaschke products introduced by Herman [Her79]. Of special relevance are the Arnold tongues corresponding to rational rotation numbers, since those are precisely the parameters for which the maps have attracting or parabolic periodic orbits on \( \mathbb{S} \). If the maps \( f_a \) are not homeomorphisms but degree 2 covers of \( \mathbb{S} \), we cannot assign a rotation number to them. However, tongues can still be defined as sets of parameters for which \( f_a \) has an attracting cycle in \( \mathbb{S} \). We can associate a type \( \tau(a) \) to every such \( f_a \), where \( \tau(a) \) is a periodic point of the doubling map and hence describes
the rotation patterns of the attracting cycle of \( f_a \) (see section 3 for details). In this setting, a tongue \( T_τ \) is defined as the open set of parameters \( a ∈ Δ \) of type \( τ \). In particular, if the point \( τ ∈ \mathbb{S}^1 \) has period \( p \) under the doubling map, then \( T_τ \) is a set of parameters for which \( f_a \) has an attracting cycle of period \( p \). Tongues were studied by Misiurewicz and Rodrigues [MR07, MR08] for the double standard family of perturbations of the doubling map

\[
θ → 2θ + α + (β/π) \sin(2πθ) \pmod{1}
\]

where \( 0 < θ < 1 \), \( 0 ≤ α ≤ 1 \) and \( 0 ≤ β ≤ 1 \). Later on, Dezotti [Dez10] used the complex extension of the double standard maps on the punctured plane, which is given by \( z → e^{2πiα}z^2e^{β(z-1/2)} \), in order to prove the connectivity of the tongues. This family was also studied by de la Llave et al [dLLSS08], who considered entropy related issues of the \( k \)th standard maps \( θ → kθ + α + ε \sin(2πθ) \pmod{1} \) for \( ε \) small and \( k ≥ 2 \).

Given that the Blaschke products \( B_τ \) are rational perturbations of the doubling map, \( B_τ \) may be considered as the rational analogue of the double standard family. Although there is no explicit simple expression for the restriction of \( B_τ \) to \( \mathbb{S}^1 \), the global dynamics are simpler than in the transcendental case. If \( |α| ≥ 2 \), the \( B_τ \) are degree 2 coverings of the unit circle and the tongues are well defined. Inspired by the mentioned works of Misiurewicz, Rodriguez and Dezotti, we show that they are connected and simply connected. More precisely, we prove the following theorem.

**Theorem A.** Given any periodic point \( τ \) of the doubling map the following results hold.

(a) The tongue \( T_τ \) is not empty and consists of three connected components (only one connected component if we consider the parameter plane modulo the symmetries given by the third roots of the unity).

(b) Each connected component of \( T_τ \) contains a unique parameter \( r_τ \), called the root of the tongue, such that \( B_τ \) has a superattracting cycle in \( \mathbb{S}^1 \). The root \( r_τ \) satisfies \( |r_τ| = 2 \).

(c) Every connected component of \( T_τ \) is simply connected.

(d) The boundary of every connected component of \( T_τ \) consists of two curves which are continuous graphs as function of \( |a| \) and intersect each other in a unique parameter \( a_τ \) called the tip of the tongue.

The boundary of a tongue \( T_τ \) of period \( p \) is the union of two curves of parameters which intersect at the tip \( a_τ \) of the tongue (see figure 7). These boundary parameters correspond to maps \( B_τ \), which have a persistent parabolic cycle of period \( p \) and multiplier 1 in \( \mathbb{S}^1 \). On the tip \( a_τ \), of the tongue, the parabolic cycle of \( B_τ \) has multiplicity 3, i.e. \( B_τ \) has a cycle \( \{z_0, \cdots, z_{p-1}\} \) of period \( p \), multiplier 1 and second derivative zero \((B_τ^p)'(z_0) = 0\) in \( \mathbb{S}^1 \). Along \( ∂T_τ \setminus a_τ \), there is a persistent saddle-node bifurcation taking place: two period \( p \) cycles collide in \( \mathbb{S}^1 \) and exit it (see figure 6). Notice that these bifurcations along curves cannot happen for a uniparametric family of holomorphic maps which depend holomorphically on the parameter. The real saddle-node bifurcation was studied by Misiurewicz and Pérez [MP08] from a complex point of view. They characterized, depending on the sign of the Schwarzian derivative, whether the period \( p \) cycles exiting the unit circle (or the real line) are attracting or repelling. Crowe et al [CHRSC89] showed that this type of bifurcations also occurs in the Tricorn, the connectedness locus of the antipolynomials \( p_2(z) = z^2 + c \). Their result was later generalized by Hubbard and Schleicher [HS14]. They studied these bifurcations in the Multicorns, the bifurcation loci of the antipolynomials \( p_3(z) = z^d + c \), by using the holomorphic index of the fixed points. Using the holomorphic index and results of algebraic geometry such as Chevalley’s theorem (see theorem 4.6, see [Har77]), we prove the following result.
Theorem B. Let \( \tau \) be the tip of a tongue \( T \) of period \( p \). Then, there exists a neighborhood \( U \) of \( \tau \) such that if \( a \in U \) then, either \( a \in T \) or \( a \in \partial T \) or \( a \) belongs to a hyperbolic component of disjoint type, i.e. a hyperbolic component for which the maps \( B_a \) have two attracting cycles other than \( z = 0 \) and \( z = \infty \).

Using the same techniques utilized in theorem B and the parametrization of disjoint hyperbolic components described in [CFG15] (see theorem 2.4) we also prove that any parameter \( a \) with \( |a| > 2 \) such that \( B_a \) has a parabolic cycle of multiplicity 3 in \( S^1 \) corresponds to a tip of a tongue (see proposition 4.9). We conclude that any parameter \( a \) with \( |a| > 2 \) such that \( B_a \) has a parabolic cycle in \( S^1 \) belongs to the boundary of a tongue (see corollary 4.10).

If \( a \) belongs to the open annulus \( A_{1,2} \) of inner radius 1 and outer radius 2, then the Blaschke products \( B_{1,2} \) are no longer degree two coverings of the unit circle. Despite that, the attracting cycle associated to a given tongue may be continued for parameters within \( A_{1,2} \). This leads to the concept of extended tongues \( ET \), open connected sets of parameters \( a, |a| > 1 \), for which \( B_{1,2} \) has an attracting cycle which can be real analytically continued to the attracting cycle of a tongue \( T \). However, extended tongues are not disjoint. Indeed, if \( a \in A_{1,2} \), then the two free critical points of \( B_a \) lie on the unit circle and their orbits are not related by symmetry. Therefore, they may accumulate on different attracting cycles, allowing a parameter to belong to two different extended tongues simultaneously. We focus on the study of the extended fixed tongue \( ET_0 \) and prove the following theorem (see figure 8).

Theorem C. Given two connected components of the fixed tongue \( T_0 \), the intersection of their extensions in \( A_{1,2} \) is empty. The boundary of every connected component of the extended fixed tongue \( ET_0 \) consists of two disjoint connected components. The exterior component consists of parameters for which there is a parabolic fixed point of multiplier 1. The interior component consists of parameters for which there is a parabolic fixed point of multiplier \(-1\). Moreover, there is a period doubling bifurcation taking place throughout the curve of interior boundary parameters.

The paper is structured as follows. In section 2 we introduce the basic properties of the Blaschke products \( B_a \) and present some alternative parametrizations which are useful later on. In section 3 we introduce the concept of tongues for the family \( B_a \) and prove theorem A. In section 4 we study the bifurcations which take place around the tip of the tongues proving theorem B. Finally, in section 5 we see how tongues extend within the annulus \( A_{1,2} \) and study the extended fixed tongue \( ET_0 \) proving theorem C.

2. Preliminaries on the Blaschke family

In this section we give an introduction to the Blaschke products \( B_a \) as in (1). We first study the basic properties of the dynamical plane and the parameter plane. Afterwards we consider some reparametrizations of the family which are useful later on. We refer to [CFG15] for proofs of the results and a more detailed description of the family.

We consider the degree 4 Blaschke products of the form

\[
B_a(z) = e^{2\pi i \frac{1}{3}} \frac{z - a}{1 - az},
\]

where \( a \in \mathbb{C} \) and \( t \in \mathbb{R}/\mathbb{Z} \). Since \( B_a \) leaves invariant the unit circle, it is symmetric with respect to \( S^1 \), i.e. \( B_{-a}(z) = \bar{z} \circ B_a \circ \bar{z}(z) \) where \( \bar{z}(z) = 1/z \). Even if it is sometimes necessary to consider the parameter \( t \), the next lemma tells us that, for the purpose of classification, we can omit it. The proof is straightforward.
Lemma 2.1. Let $\alpha \in \mathbb{R}$ and let $\eta(\zeta) = e^{-2\pi i \alpha \zeta}$. Then $\eta$ conjugates the maps $B_{\alpha,t}$ and $B_{\alpha e^{-2\pi i \alpha},t + 3\alpha}$. In particular, $B_{\alpha,t}$ is conjugate to $B_{\alpha e^{-2\pi i \alpha},t}$.

The orbits of the critical points, i.e. the points $c \in \hat{\mathbb{C}}$ such that $f'(c) = 0$, control the possible stable dynamics of any rational map $f$. Since the Blaschke products $B_a$ have degree $d = 4$, they have $2d - 2 = 6$ critical points counted with multiplicity. The fixed points $z = 0$ and $z = \infty$ are critical points of multiplicity 2 and hence superattracting fixed points of local degree 3. The other two critical points, denoted by $c_{\pm}$, are given by

$$c_{\pm} = c_{\pm}(a) = a \cdot \frac{1}{3|a|^2} \left(2 + |a|^2 \pm \sqrt{(|a|^2 - 4)(|a|^2 - 1)}\right). \quad (3)$$

The next lemma tells us that the parameters $a$ and $t$ depend continuously on the critical points.

Lemma 2.2 ([CFG15, lemma 3.2]). Given a Blaschke product $B_{\alpha,t}$ as in (2) with $|a| \geq 2$ or $|a| < 1$, the parameter $a$ is continuously determined by the critical points $c_{\pm}$. Moreover, if the image $B_{\alpha,t}(z_0) = \{0, \infty\}$ of a point $z_0 \in \mathbb{C}^*$ is fixed, then $t$ depends continuously on $a$.

The positions of the free critical points, together with the ones of the pole $z_\infty = 1/\pi$ and the zero $z_0 = a$ determine the possible stable dynamics of the Blaschke products. Indeed, if the pole is not in $\mathbb{D}$, then $B_a(\mathbb{D}) = \mathbb{D}$ and all points in $\mathbb{D}$ tend under iteration of $B_a$ to the superattracting cycle $z = 0$. The possible configurations can be summarized, depending on the modulus of $a$, as follows (see figure 1).

- If $|a| < 1$ then $z_\infty \in \mathbb{C} \setminus \mathbb{D}$ and $\mathcal{J}(B_a) = \mathbb{S}^1$.
- If $|a| = 1$ then the two free critical points, the pole and the zero collide in a single point. For these parameters, the Blaschke products degenerate to the family of cubic polynomials $-az^3$ and $\mathcal{J}(B_a) = \mathbb{S}^1$.
- If $1 < |a| < 2$ then $z_\infty \in \mathbb{D}$ and $c_{\pm} \in \mathbb{S}^1$. The two critical orbits are independent, which may lead to up to two attracting or parabolic cycles in $\mathbb{S}^1$.
- If $|a| = 2$ then $z_\infty \in \mathbb{D}$ and the two critical points collide in a single one $c \in \mathbb{S}^1$. There can be at most one attracting cycle in $\mathbb{S}^1$ and $B_a|_{\mathbb{S}^1}$ is a degree two cover.
- If $|a| > 2$ then $z_\infty \in \mathbb{D}$, the critical points do not belong to $\mathbb{S}^1$ and are symmetric with respect to it, i.e. $c_{\pm} = 1/\pi$. Consequently, the critical orbits are symmetric with respect to $\mathbb{S}^1$ and therefore have the same (or symmetric) asymptotic behaviour. Moreover, $B_a|_{\mathbb{S}^1}$ is a degree two cover.

Along this paper we mainly focus on parameters $a$ such that $|a| \geq 2$ although we analyse the case $1 < |a| < 2$ in section 5.

We finish this first part of the section stating two results on the parameter plane which will be useful later on. As we can see in figure 2, there are some symmetries which can be observed in the parameter plane. They are explained in the following lemma (see [Can15, lemma 5.1.1] for details, compare [CFG15, lemma 4.1]).

Lemma 2.3. Let $a, b \in \mathbb{C} \setminus \mathbb{S}^1$. Then $B_a$ and $B_b$ are conformally conjugate if and only if $b = \xi a$ or $b = \xi \bar{a}$, where $\xi$ is a third root of the unity.

The following theorem, [CFG15, theorem C], tells us that every disjoint hyperbolic component $\Omega$, i.e. every connected set of parameters $a$ such that $B_a$ has two different attracting cycles not contained in $\mathbb{S}^1$ and other than $z = 0$ and $z = \infty$, is homeomorphic to the unit disk. The homeomorphism is given by the multiplier map, which associates, to every $a \in \Omega$, the multiplier of the attracting cycle on which the orbit of $c_+$ accumulates.
Theorem 2.4 ([CFG15, theorem C]). Let \( \Omega \subset \{ a \in \mathbb{C}, |a| > 2 \} \) be a disjoint hyperbolic component. Then, the multiplier map is a homeomorphism between \( \Omega \) and the unit disk.

2.1. Reparametrizing the Blaschke family

In this section we describe some alternative parametrizations of \( B_a \) which are particularly useful when we restrict to the unit circle. Let \( a = re^{2\pi i \alpha} \) with \( r \in (1, \infty) \) and \( \alpha \in [0, 1/3) \) (or \( \alpha \in \mathbb{R}/\mathbb{Z} \)). From lemma 2.1 we know that \( B_a = B_{a,0} \) as in (1) is conformally conjugate to \( B_{r,3\alpha} \) as in (2). It is enough to restrict to parameters \( \alpha \in [0, 1/3) \) due to symmetry on the parameter plane (see lemma 2.3). Notice that if \( \alpha \in [0, 1/3) \) we have a one to one correspondence between the parameters \( a \) of the family \( B_a \) and the parameters \( (r, \alpha) \) of \( g_{r,\alpha} := B_{r,3\alpha} \).

Summarizing, we consider the circle maps

\[
g_{r,\alpha}(e^{2\pi i \xi}) = e^{6\pi i \alpha} e^{6\pi i \alpha} \frac{e^{2\pi i \xi} - r}{1-re^{2\pi i \xi}},
\]

where \( r \in (1, \infty) \) and \( \alpha \in [0, 1/3) \). Its lift has the form

\[
h_{r,\alpha}(x) = 3x + 3\alpha + \frac{1}{2\pi i} \log \left( \frac{e^{2\pi i \xi} - r}{1-re^{2\pi i \xi}} \right).
\]

We shall often use \( g_{r,\alpha} \) instead of \( B_{r,3\alpha} \) given that its lift is somehow simpler. Indeed, it follows directly from its expression that \( h_{r,\alpha} \) is strictly increasing with respect to \( \alpha \).
Lemma 2.5. Let \( r < 2 \). Then, the lift \( \alpha \rightarrow \alpha \partial h_{r,\alpha} \) satisfies that \( \alpha \partial h_{r,\alpha} \) is non-negative for all \( x \). Moreover, for any \( p \in \mathbb{N} \), the mapping \( \alpha \rightarrow h^p_{r,\alpha}(x) \) is strictly increasing and, if \( r \geq 3 \), then \( h^p_{r,\alpha}(x) \geq 1 \) for all \( x, \alpha \in \mathbb{R} \).

Proof. We prove that \( \alpha \partial h_{r,\alpha}(x) \) is non-negative for all \( x \), and hence so is \( \frac{\partial}{\partial \alpha} h^p_{r,\alpha}(x) \) for all \( p \). Then, strict monotonicity with respect to \( \alpha \) for all \( p \) follows from the fact that we have it for \( p = 1 \). We also prove that \( \frac{\partial}{\partial \alpha} h_{r,\alpha}(x) \geq 1 \) if \( r \geq 3 \). Notice that \( \frac{\partial}{\partial \alpha} h_{r,\alpha}(x) \) is given by the formula

\[
\frac{\partial}{\partial \alpha} h_{r,\alpha}(x) = 3 + \frac{1 - r^2}{1 + r^2 - 2r \cos(2\pi x)}. \tag{6}
\]

It can easily be seen that this expression is non-negative for \( r \geq 2 \). Indeed, the minimum of this function is taken whenever \( x = 0 \), and

\[
\frac{\partial}{\partial \alpha} h_{r,\alpha}(0) = 3 + \frac{1 - r^2}{1 + r^2 - 2r} = 3 + \frac{(1 + r)}{(1 - r)}
\]

For \( r > 1 \) this is an increasing function which is equal to zero for \( r = 2 \). Moreover, it is greater than 1 when \( r \geq 3 \).

\( \Box \)
It will also be useful to consider the circle maps $g_{a,b}$ as restrictions of the rational maps
\[
G_{a,b}(z) = b z^3 - \frac{z - a}{1 - az},
\]
where $a, b \in \mathbb{C}$. The $G_{a,b}$ define a degree 4 family of almost bicritical maps unless $a = \pm 1$, when they degenerate to the degree 3 polynomials $b z^3$. By almost bicritical family we mean that, as is the case for the Blaschke products $B_{a}$, the maps $G_{a,b}$ have at most two free critical points whilst the other ones are permanent superattracting fixed points. Notice that these maps are not symmetric with respect to the unit circle. Similarly to the Blaschke products $B_{a}$, the points $z = 0$ and $z = \infty$ are superattracting fixed points of local degree 3 for all $G_{a,b}$. The two free critical points are given by
\[
\alpha, \beta = \frac{1}{3a} \left( 2 + a^2 \pm \sqrt{(a^2 - 4)(a^2 - 1)} \right)
\]
and are the solutions of $3a z^2 - 2(a^2 - 2)z + 3a = 0$. In particular we have that $\alpha \cdot \beta = 1$ and none of them is equal to zero if $a \neq 0$ and $a = \infty$.

We say that a parameter $(a, b)$ is escaping if the orbit of any of the critical points accumulates on $z = 0$ or $z = \infty$. We finish this section studying the non-escaping set of the family $G_{a,b}$, i.e. the set of parameters $(a, b)$ for which none of the critical orbits accumulates on $z = 0$ or $z = \infty$.

**Lemma 2.6.** The non-escaping set of the family $G_{a,b}$ is bounded in the $a$-parameter, i.e. there exists a constant $C > 0$ such that if $|a| > C$ then the parameter $(a, b)$ is escaping.

**Proof.** We will prove that, if $|a|$ is big enough then one of the critical orbits accumulates on $z = 0$ or $z = \infty$. Notice that the other critical orbit may accumulate on a bounded attracting cycle even if $|a|$ tends to infinity.

We distinguish two cases. Assume first that $|b| \geq 1$. We have that, if $|z| > \lambda(|a| + 1)$ with $\lambda > 1$, then $|G_{a,b}(z)| > \lambda|b| |z|$. Indeed, one can check that $|z - a| > \lambda$ and that
\[
|z|^2 > |z|(|a|+1) = |za| + |z| > |za|+1 > |z - a|.
\]
Therefore, we have
\[
|G_{a,b}(z)| = |b| |z|^3 \frac{|z - a|}{|1 - az|} > |b| |z|^3 \frac{\lambda}{|z|^2} = \lambda|b| |z|.
\]

As $|a|$ tends to infinity the critical point $c_+(a)$ tends to $2a/3$ and $c_-(a)$ tends to $3/(2a)$. Consequently, the modulus of the critical value $v_n = G_{a,b}(c_+(a))$ grows as $M |a|^2$ for some $M > 0$ and, for $|a|$ large enough, $|v_n| > \lambda(|a|+1)$ with $\lambda > 1$. We conclude that $|G_{a,b}(v_n)| \to \infty$ when $n \to \infty$. Therefore, if $|a|$ is large enough and $|b| \geq 1$ then the parameter $(a, b)$ is escaping.

Consider now the case $|b| < 1$. First we prove that, if $|a|$ is big enough and $|z| < 1/(2|a|)$ then $|G_{a,b}(z)| < 3|b| |z|/4$. From these hypothesis we conclude that $|z| < 1/2$ and obtain the inequalities
\[
|z - a| < |z| + |a| < \frac{1}{2|a|} + |a| < \frac{|a|}{2} + |a| = 3|a|/2
\]
and
\[ |1 - az| > 1 - |az| > 1 - \frac{1}{2} = \frac{1}{2}. \]

Therefore, we have
\[ |G_{a,b}(z)| = \frac{|b||z|^3 |z - a|}{|1 - ac|} < |b||z|^3 |a| < \frac{3}{2} |b||z|^2 < \frac{3|b||z|}{4}. \]

Since \( c_{-}(a) \) converges to \( 3/(2a) \) as \( a \) tends to infinity, we conclude that the modulus of the critical value \( v = G_{a,b}(c_{-}) \) decreases as \( M/|a|^2 \) for some \( M > 0 \). Hence, for \( |a| \) large enough, \( |v| < 1/(2|a|) \) and \( |G_{a,b}^n(v)| \to 0 \) when \( n \to \infty \). Therefore, if \( |a| \) is large enough and \( |b| > 1 \) then the parameter \((a, b)\) is escaping. \( \square \)

**Lemma 2.7.** For fixed \( a_0 \in \mathbb{C}, a_0 \neq \pm 1 \), the non-escaping set of \( G_{a_0,b} \) is bounded with respect to the parameter \( b \), i.e. there exists a constant \( C(a_0) > 0 \) such that if \( |b| > C(a_0) \) then the parameter \((a_0, b)\) is escaping.

**Proof.** It is enough to prove that if \( |b| \) is large enough then the orbit of one of the critical points accumulates on infinity. The critical values, i.e. the images of the critical points, of \( G_{a_0,b} \) are given by
\[ v_{\pm} = G_{a_0,b}(c_{\pm}) = bc_{\pm} \frac{c_{\pm} - a_0}{1 - c_{\pm}a_0}. \]
where the critical points \( c_{\pm} \) do not depend on \( b \). Moreover, if \( a = \pm 1 \), at least one of the critical values, say \( v \), is different from zero. Indeed, the rational maps \( G_{a_0,b} \) have a unique preimage of zero at \( z = a \). The claim holds since the critical points collide only if \( a = \pm 2 \) and \( c_{1}(\pm 2) = c_{-}(\pm 2) = \pm 1 \). If \( |b| \) is large enough the critical value \( v \) satisfies \( |v| > \lambda |a_0| + 1 \) with \( \lambda > 1 \). As in the proof of lemma 2.6, we conclude that the orbit of \( v \) accumulates on infinity and, therefore, for \( |b| \) large enough the parameter \((a_0, b)\) is escaping. \( \square \)

### 3. Tongues of the Blaschke family

In this section we introduce the concept of tongue for the Blaschke family \( B_a \) restricted to the set of parameters \( a \) such that \( |a| \geq 2 \). The definition generalizes to more general almost bicritical families \( f_a \) which leave the unit circle invariant and such that \( f_a^{-1} \) is strictly increasing of degree 2 (see [MR07]). Recall that, by almost bicritical families we mean that the maps \( f_a \) have at most two free critical points whilst the other ones are permanent superattracting fixed points.

Let \( \{f_a\}_{a \in \Delta} \) where \( \Delta \subseteq \hat{\mathbb{C}} \) or \( \Delta \subseteq \mathbb{R}^2 \), be a family of orientation preserving homeomorphisms of the unit circle. We can assign a rotation number to each of its members as follows. If \( F_a \) is a lift of \( f_a \), then the rotation number of \( f_a \) is defined as
\[ \rho(f_a) = \lim_{n \to \infty} \frac{F_a^n(x)}{n}, \]
where \( x \in \mathbb{R} \). It is well known that the limit exists and it is independent of \( x \) (see e.g. [dMvS93]). Since any two lifts differ in an integer constant, this limit provides a well defined rotation number in \( \mathbb{R}/\mathbb{Z} \). If the maps \( f_a \) are degree 2 covers of \( S^1 \), then the generalized limit does not only depend on the point \( x \), but provides a semiconjugacy between \( f_a \) and the doubling map. Indeed, the following lemma holds.

3472
Lemma 3.1 ([MR07, lemmas 3.1 and 3.3]). Let $F_a: \mathbb{R} \to \mathbb{R}$ be a continuous and increasing map depending continuously on $a$. Suppose that $F_a(x + k) = F_a(x) + 2k$ for any integer $k$ and for all $x \in \mathbb{R}$. Then, the limit

$$H_a(x) = \lim_{n \to \infty} \frac{F_a^n(x)}{2^n}$$

exists uniformly on $x$. The map $H_a$ is increasing, continuous, depends continuously on $a$ and satisfies $H_a(x + k) = H_a(x) + k$ for any integer $k$ and for all $x \in \mathbb{R}$. Moreover, $H_a$ semiconjugates $F_a$ with the multiplication by 2, i.e. $H_a(F_a(x)) = 2H_a(x)$ for any real $x$. Furthermore, if $F_a$ is increasing with respect to $a$ (for any fixed $x$), then $H_a$ is also increasing with respect to $a$.

If $F$ is a lift of a degree 2 orientation preserving map $f: S^1 \to S^1$, then $F$ satisfies the conditions of Lemma 3.1 and is semiconjugate to the doubling map $\theta \to 2\theta$ via $H: \mathbb{R} \to \mathbb{R}$. Let $h$ be the degree 1 function of the circle which has $H$ as its lift. Then, $h$ semiconjugates $f$ with the doubling map of the circle $\theta \to 2\theta$ (mod 1) (equivalently given by $R_a(z) = z^2, |z| = 1$). The following lemmas tell us that the semiconjugacy is unique and sends periodic points to periodic points of the same period.

Lemma 3.2 ([Boy06]). Let $f$ be a degree 2 orientation preserving map of the circle. Then there exists a unique degree 1 map $h$ of the circle which semiconjugates $f$ with the doubling map $R_2$.

Lemma 3.3 ([MR07, lemma 3.2]). The semiconjugating map $h$ sends points of period $k$ to points of period $k$.

Using this unique semiconjugacy $h_a$ of $B_{d\theta^{[a]}}$, tongues can be defined as sets of parameters for which $B_a$ has an attracting cycle in $S^1$. Before defining them we introduce a technical lemma and some notation. We denote by $(x_0) = \{x_0, x_1 = B_a(x_0), \cdots, x_{p-1} = B_a^{-1}(x_0)\}$ a period-$p$ attracting or parabolic cycle and by $A^r((x_0))$ its immediate basin of attraction.

Lemma 3.4. A Blaschke product $B_a$, where $|a| \geq 2$, can have at most one attracting or parabolic cycle $(x_0)$ in the unit circle, which has a real multiplier. If the cycle is attracting, the two critical points lie in the same connected component of $A^r((x_0))$. If the cycle is parabolic, then it has multiplier $\lambda = 1$ and either every point $x_a$ of the cycle lies in the boundary of a unique connected component of $A^r((x_0))$ which intersects the unit circle (see figure 6(b)) and the two critical points lie in the same connected component of $A^r((x_0))$ or there are two such components which are symmetric and which do not intersect the unit circle (see figure 6(a)).

Proof. The multiplier is real since $S^1$ is invariant under $B_a$. It follows from the symmetry of the Blaschke family that if the two free critical points do not lie in the unit circle, then their orbits are symmetric with respect to $S^1$. Hence, if one of the critical orbits accumulates on an attracting or parabolic cycle $(x_0)$ in $S^1$, so does the other one. Given that any attracting or parabolic cycle has a critical point in its immediate basin of attraction, this proves that there can be at most one attracting or parabolic cycle in the unit circle. Moreover, every connected component of $A^r((x_0))$ which intersects $S^1$ is symmetric with respect to it. If the cycle is attracting, then all connected components of $A^r((x_0))$ intersect the unit circle and one of them contains both free critical points. This finishes the attracting case.

Now suppose that $(x_0)$ is a parabolic cycle. Then it has multiplier $\lambda = 1$. Indeed, since $\lambda$ is real, $\lambda = \pm 1$, but it is positive since $B_a(\theta)$ is increasing (see lemma 2.5). Hence, all the connected components of $A^r((x_0))$ have the same period $p$ as has the cycle $(x_0)$. If a connected component of $A^r((x_0))$ intersects the unit circle, then we have a cycle of such components.
intersects $S^1$. As in the attracting case, we conclude that there is a connected component of the cycle which contains both free critical points and there can be no other parabolic cycle. Finally, if no connected component of $A'(x_0)$ intersects $S^1$, by symmetry, every point $x_0$ of the cycle has at least 2 such components attached to it. Since every cycle of parabolic attracting basins contains at least a critical point and there are only two free critical points, we conclude that every point of the cycle has exactly 2 components of $A'(x_0)$ attached to it.

Definition 3.5. Assume that $B_a$, where $|a| \geq 2$, has an attracting cycle $(x_0)$ in the unit circle. Then, the point $x_j \in (x_0)$ such that the critical points lie in the connected component of $A'(x_0)$ which contains $x_j$ is called the marked point of the cycle.

We generally rename the cycle so that $x_0$ denotes the marked point. Now we can formalize the concept of tongue for degree two covers of the circle. Let $H_a$ be the continuous map given by lemma 3.1 which semiconjugates the lift $F_a$ of $B_a|_{\mathbb{Z}}$ to the doubling map. Then tongues for the Blaschke products $B_a$ are defined as follows.

Definition 3.6. Let $B_a$ be a Blaschke product. We say that a parameter $a$, $|a| \geq 2$, is of type $\tau$ if $B_a|_{\mathbb{Z}}$ has an attracting cycle $(x_0)$ and $H_a(x_0) = \tau$, where $x_0$ is the marked point of the cycle. The tongue $T_\tau$ is defined as the set of parameters $a$, $|a| \geq 2$, such that $a$ is of type $\tau$ (see figure 3).

The type $\tau(a)$ is a well defined number of $\mathbb{R}/\mathbb{Z}$ by lemma 3.2. Hence, we may assume that $\tau(a) \in [0, 1)$. Notice that in the previous definition we use an abuse of notation, naming $x_0$ both the point in the unit circle and its lifted equivalent in the real line.

Given that $H_a$ sends periodic points to periodic points (see lemma 3.3), any realizable type $\tau \in \mathbb{S}$ is a periodic point of the doubling map. Consequently, if a point $\tau \in \mathbb{S}$ has period $p$ under the doubling map, then the tongue $T_\tau$ consists of a set of parameters for which $B_a|_{\mathbb{Z}}$ has an attracting cycle of period $p$. It also follows from lemma 3.3 and the continuity of $H_a$ with respect to parameters that tongues are open subsets of $\mathbb{C} \setminus \mathbb{D}_2 = \{a \in \mathbb{C} \mid |a| \geq 2\}$. Therefore, a parameter $a$ with $|a| = 2$ such that $B_a$ has an attracting cycle in $\mathbb{S}$ is said to be in the interior of a tongue (see section 5).

It follows from lemma 3.4 that the tongues are disjoint. Indeed, if two different tongues would intersect, we would have parameters with two different attracting cycles in $\mathbb{S}$, which is not possible.

The remaining part of the section is devoted to prove theorem A, which explains the basic topological properties of the tongues of the Blaschke family. Its proof splits in the next two sections.

3.1. Connectivity of the tongues: proof of statements (a) and (b) of theorem A

In this section we prove statements (a) and (b) of theorem A. The proof uses quasiconformal tools. We refer to [Ahl06] and [BF14] for an introduction to the topic.

The proof is inspired by Dezotti [Dez10] and consists in performing a continuous change of the multiplier of the attracting cycle $(x_0) \subset \mathbb{S}$. Given a parameter $a$ of type $\tau$, with multiplier $\lambda \neq 0$, we make a quasiconformal modification of the function that changes the multiplier to $\rho \in (0, 1)$ while leaving the rest of the dynamics unchanged, obtaining a new parameter $a(\rho)$.

With this modification we shall obtain a path $\gamma \subset T_\tau$ landing on a parameter $r_i \in T_\tau$ having a superattracting fixed point. It follows from the construction that every connected component of a tongue $T_\tau$ contains a superattracting parameter. The proof is finished by showing that, for every periodic point $\tau$ of the doubling map, there exists a unique parameter $r_{\tau}$ of the form $2e^{2\pi i \alpha}$ with $\alpha \in [0, 1/3)$ such that $B_{r_{\tau}}$ has a superattracting periodic point and has type $\tau$. 

3474
Moreover, this also shows that any tongue $T_c$ is not empty and has a unique connected component modulo the symmetries given by the third root of unity.

We begin by changing the multiplier. The main steps of this quasiconformal construction are the following.

(a) First we consider a linearising map $\phi$ of $B_a^p$ around the attracting periodic point $x_0$, which has period $p$ and multiplier $\lambda \in (0, 1)$.
(b) Then we define a quasiconformal conjugacy $X$ between the maps $z \mapsto \lambda z$ and $z \mapsto \rho z$, where $\rho \in (0, 1)$.
(c) We continue by defining a $B_a$-invariant Beltrami form $\mu_\rho$. Around $x_0$, it is defined by pulling back the standard Beltrami coefficient $\mu \equiv 0$ by the quasiconformal homeomorphism $X \circ \phi$. Then we spread it by the dynamics of $B_a$.
(d) Finally we consider the map $\varphi_{\rho} \circ B_{\phi} \circ \varphi_{\rho}^{-1}$, where $\varphi_{\rho}$ is the integrating map of $\mu_\rho$ which fixes zero, infinity and $x_0$ given by the measurable Riemann mapping theorem (see [Ahl06, p 57], [BF14, theorem 1.28]). This map is holomorphic and linearly conjugate to a member $B_{\mu_\rho}$ of the Blaschke family.

We now proceed to make the construction precise. Let $a \in T_c$. Recall from definition 3.6 that then $B_{\mu_\rho}$ has an attracting cycle $(x_0) = \{x_0, \ldots, x_{p-1}\} \subset S^1$ of multiplier $\lambda$. We assume that $x_0$ lies in the component of the immediate basin which contains the critical points. Notice that $\lambda \in \mathbb{R}$ since $B_{\mu_\rho}$ is an endomorphism of the unit circle. Let $\phi : U \to \partial$ be the K"{a}enigs linearizer of $B_{\mu_\rho}$ around $x_0$, where $U$ denotes the maximal neighbourhood of $x_0$ in which $\phi$ can be taken to be conformal (see [Mil06, theorem 8.2 and lemma 8.5]), normalized as in the following lemma.

Lemma 3.7. The map $\phi : U \to \partial$ may be chosen to satisfy $\phi(I(z)) = \overline{I(z)}$, where $I(z) = 1/z$. Moreover, $U = I(U)$.

Proof. The map $\phi$ sends invariant curves of $B_{\mu_\rho}$ to invariant curves of $z \mapsto \lambda z$, which are straight lines going through $z = 0$ since $\lambda$ is real. Hence, we may assume that $\phi(U \cap S^1) \subset \mathbb{R}$.
postcomposing $\phi$ with a rotation. With the previous normalization, notice that the holomorphic map $\tilde{\phi}(z) = \overline{\phi(U \cap \mathbb{D})}$ coincides with $\phi$ on $U \cap \mathbb{D}$ and, therefore, it equals $\phi$. The symmetry of $U$ follows from the symmetry of $\phi$.

In the following lemma we introduce a quasiconformal map $X$ which is used to change the multiplier of an attracting cycle. We refer to [Dez10] and [BF14] for a proof.

**Lemma 3.8.** Let

$$X' : \mathbb{C}^* \to \mathbb{C}^*$$

$$z \to |z|^\alpha z,$$

where $\alpha \in (-1, \infty)$, and let $0 < R < 1$ and $0 < r < 1$. Then the following hold.

(a) The Beltrami form $\mu_X = X^* \mu_0$ where $\mu_0$ denotes the Beltrami form of the standard complex structure and $*$ denotes the pull back operation, satisfies

$$\mu_X = \frac{\partial X/\partial \sigma}{\partial X/\partial z} = \frac{\alpha}{2 + \alpha} \frac{z}{\bar{z}},$$

$$\|\mu_X\|_{\infty} = \left| \frac{\alpha}{2 + \alpha} \right|.$$

(b) $X$ is invertible and satisfies $X(r e^{2\pi i \theta}) = \xi(r) e^{2\pi i \theta}$, where $\xi(r) = r^{\alpha + 1}$.

(c) Let $\alpha = \frac{\log R}{\log r} - 1$. Then $X$ sends the disk $D_R$ of radius $R$ to the disk $D_r$, of radius $r$ and, moreover, $\|\mu_X\|_{\infty} = \left| \frac{1 - \log r/\log R}{1 + \log r/\log R} \right| < 1$.

(d) Let $\lambda \in (0, 1)$. Let $\rho = \lambda(\lambda) = \lambda^{1 + \alpha}$. Then $X$ conjugates the map multiplication by $\lambda$ with the map multiplication by $\rho$, i.e. the following diagram is commutative

\[
\begin{array}{ccc}
D_R & \xrightarrow{\lambda} & D_R \\
X & \downarrow & X \\
D_r & \xrightarrow{\rho^2} & D_{pr}.
\end{array}
\]

Notice that, since $\lambda \in (0, 1)$ and $\alpha \in (-1, \infty)$, we have that $0 < \rho < 1$.

**Lemma 3.9.** The Beltrami form given by $\mu_\rho = \mu_X \circ \phi = \phi^* \mu_X$ depends analytically on $\rho$ and is invariant under $B_\rho$. Moreover, $T^* \mu_\rho = \mu_\rho$ on $U$.

**Proof.** The analytic dependence with respect to $\rho$ is obtained from the explicit expression of $\mu_X$ and the fact that $\alpha = \frac{\log \rho}{\log \lambda} - 1$. Invariance under $B_\rho$ follows from the next commutative diagram.
To see that \( \mu \equiv \rho \ast I \), we have to check that 
\[
(\mu \circ \phi) = (\rho \ast z z)^{1/2}. 
\]
(see [BF14, definition 1.3]). From the explicit expression of the Beltrami form that we get from the pullback (see [BF14, equation (1.9)]), we have
\[
(\mu \alpha) = \frac{\phi(z)}{\phi'(z)}. 
\]
The result follows since \( \phi(1/\bar{z}) = \bar{\phi(z)} \) and \( \phi'(z) = -\bar{\phi(1/\bar{z})}/z^2 \).

Once we have this Beltrami form given by \( \mu \rho \) in \( U \), we spread it to \( \mathbb{C} \) by defining:
\[
\mu_{\rho}(z) = \frac{\alpha/2 \phi(z)}{1 + \alpha/2 \phi'(z)}. 
\]
The result follows since \( \phi(1/\bar{z}) = \bar{\phi(z)} \) and \( \phi'(z) = -\bar{\phi(1/\bar{z})}/z^2 \).

Once we have this Beltrami form given by \( \mu_{\rho} \), we spread it to \( \mathbb{C} \) by defining:
\[
\mu_{\rho} = \begin{cases} 
\mu_{\rho} & \text{on } U \\
(B_{\rho}^n) \mu_{\rho} & \text{on } B_{\rho}^{-n}(U) \setminus B_{\rho}^{-n+1}(U), \text{ for } n > 1 \\
\mu_0 & \text{otherwise},
\end{cases} 
\]
where \( \mu_0 \equiv 0 \). Then \( \mu_{\rho} \) is well defined since it is \( B_{\rho}^n \)-invariant. It depends analytically on \( \rho \) since we are pulling back by a holomorphic map an almost complex structure which depends analytically on \( \rho \). Furthermore, since \( \mu_{\rho} \) is symmetric with respect to \( \mathbb{S} \) and \( \mu_{\rho} \) is defined recursively by pulling back by \( B_{\rho} \), which is also symmetric with respect to \( \mathbb{S} \), \( \mu_{\rho} \) also satisfies \( \mathcal{I} \mu_{\rho} = \mu_{\rho} \) for all \( z \in \mathbb{C} \) (see [BF14, exercise 1.2.5]).

Since \( \mu_{\rho} \) is built pulling back \( \mu_{\rho} \) by holomorphic mappings and we have that \( \|\mu_{\rho}\|_{\infty} < 1 \), we also have that \( \|\mu_{\rho}\|_{\infty} < 1 \). Let \( \phi_{\rho} \) be the integrating map obtained by applying the measurable Riemann mapping theorem (see [Ahl06, p 57], [BF14, theorem 1.28]) such that it fixes 0, \( x_0 \) and \( \infty \). The next lemma follows from uniqueness of the integrating map.

**Lemma 3.10.** The integrating map \( \phi_{\rho} \) is symmetric with respect to \( \mathbb{S} \).

**Proof.** Consider the map \( \phi_{\rho}(z) = \mathcal{I} \circ \phi_{\rho} \circ \mathcal{I}(z) \), where \( \mathcal{I}(z) = 1/\bar{z} \). By construction it fixes 0, \( x_0 \) and \( \infty \). Moreover, by symmetry of \( \mu_{\rho} \) with respect to the unit circle we have \( \phi_{\rho}(z) = \phi_{\rho}(1/\bar{z}) \).

Then, by uniqueness of the integrating map we conclude that \( \phi_{\rho}(z) = \phi_{\rho}(z) \).

Once we have \( \phi_{\rho} \), we can build our new rational map.

**Proposition 3.11.** The map \( \phi_{\rho} \circ B_{\rho} \circ \phi^{-1} \) is a rational map of degree 4 of the form \( B_{a \rho t \rho} \), as in (2), where \( t_{\rho} \in \mathbb{R} \) and \( a \rho \in \mathbb{C} \). The parameters \( a \rho \) and \( t_{\rho} \) depend continuously on \( \rho \). Moreover, the attracting fixed point \( x_0 \) of \( B_{a \rho t \rho} \) has multiplier \( \rho \).

**Proof.** By construction, the quasiregular map \( \phi_{\rho} \circ B_{\rho} \circ \phi^{-1} \) preserves the standard complex structure. Consequently, it is a holomorphic map of the Riemann sphere onto itself by Weyl’s lemma (see [Ahl06, p 16], see [BF14, theorem 1.14]). It is of the form \( B_{a \rho t \rho} \) since it has local degree 3 around 0 and \( \infty \), it has global degree 4 and it is symmetric with respect to the unit circle (see [Mil06, lemma 15.5]).

3477
We now check the dependence on parameters. Recall that $B_\rho$ has a unique critical point $c_\rho \in \mathbb{C} \setminus \mathbb{D}$ (see section 2). Since $\mu_\rho$ depends real analytically on $\rho$, the integrating map $\varphi_\rho(z)$ depends real analytically on $\rho$ for all $z \in \mathbb{C}$ by the analytic dependence on parameters of the measurable Riemann mapping theorem. Therefore, the critical point $\varphi_\rho(c_\rho) \in \mathbb{C} \setminus \mathbb{D}$ of $B_\rho$ depends real analytically on $\rho$. We conclude from lemma 2.2 that $\gamma$ depends continuously on $\rho$. The parameter $t_\rho$ is continuously determined by the parameter $a_\rho$ together with the image of a point $z_0 = 0, \infty$. Given that the map $B_{a_\rho}(x_0) = \varphi_\rho \circ B_\rho(x_0)$ depends real analytically on $\rho$, we conclude that $t_\rho$ also depends continuously on $\rho$.

Finally, let $\tilde{\varphi}_\rho(z) = \mathcal{X} \circ \varphi_\rho \circ \varphi^{-1}_\rho(z)$, where $z \in \varphi_\rho(U)$. By construction $\tilde{\varphi}_\rho$ is a quasiconformal map which conjugates $B^{\rho \circ \varphi}_\rho$ around $x_0$ to the map $z \mapsto \rho z$. Since it preserves the standard complex structure, it is a conformal map by Weyl’s lemma. Hence, it is the linearizing function and $\rho$ is the multiplier of the new cycle. 

We know from lemma 2.1 that $B_{a a_\rho \tau}$ is conjugate to $B_{a e^{-\varphi_\rho(0)}} = B_{a e^{-\varphi_\rho(0)}}$ by a conjugacy $\mathcal{L}_\rho$. This gives us a continuous curve in the set of parameters of our Blaschke family. Indeed, we have a (real analytic) curve $\gamma : (0, 1) \to \mathbb{C} \setminus \mathbb{D}_2$ defined as $\gamma(\rho) = a_\rho e^{-i\rho/3} = a(\rho)$.

Lemma 3.12. If the parameter $a$ has type $\tau$, then, for all $\rho \in (0, 1)$, the parameter $a(\rho)$ has type $\tau$.

Proof. We have already seen that $B_{a(\rho)}$ has an attracting cycle, so it has type $\tau'$. It is easy to check that the map $\mathcal{L}_\rho \circ \varphi_\rho)$ conjugates $B_{a(\rho)}$ and $B_\rho$, sending the marked periodic point $x_0$ to $g(x_0)$. Moreover, the continuous map $\mathcal{H}_\rho \circ g^{-1}$ semiconjugates $B_{a(\rho)}$ with the doubling map. Therefore, we have that

$$\tau' = \mathcal{H}_\rho \circ g^{-1}(\rho(x_0)) = \mathcal{H}_\rho(x_0) = \tau.$$

Now we have a path $\gamma(\rho) = a(\rho)$ defined for $\rho \in (0, 1)$ which gives, for each $\rho$, a parameter $a(\rho) \in T_\tau$. We want to prove that this path lands at a single point when $\rho \to 0$. Note that $|a(\rho)| \to 2$ when $\rho \to 0$ since $|B_\rho'| > C > 0$ when $|a| > 2 + \epsilon$, where $\epsilon > 0$ and $C = C(\epsilon)$ is a constant. It follows from the continuous dependence on $a$ of the semiconjugacy $\mathcal{H}_\rho$ (see lemma 3.1) that any limit point of $\gamma$ has a superattracting fixed point of period $p$.

Let $\omega$ be the limit set of $\gamma(\rho)$ when $\rho \to 0$. Since $\omega = \cap_{m \in \mathbb{N}} \gamma((0, 1/m))$ is a decreasing intersection of connected compact sets, we conclude that it is a connected set of parameters $a$ such that $|a| = 2$.

We restrict now to parameters $a$ such that $|a| = 2$. Let $a = 2e^{2i\alpha}$. Throughout the rest of the proof it will be convenient to work with $B_{2,3a}$ (equation (2)) as in section 2.1 so as to use lemma 2.5. This map is conformally conjugate to $B_\rho = B_{a_\rho}$ (equation (1)) by the rotation $\mathcal{L}_\rho(z) = e^{-2i\alpha}z$ (see lemma 2.1). For $\alpha \in (0, 1/3)$ we have a one to one correspondence between the parameters $2e^{2i\alpha}$ and the parameters $(2, 3\alpha \mod 1)$. Notice that, for all $\alpha$, $B_{2,3a}$ has a unique critical point at $c = 1$. Indeed, for $a = 2e^{2i\alpha}$, the two critical points collapse in $c(\alpha) = e^{2i\alpha}$, which is sent to $c = 1$ by the conjugacy $\mathcal{L}_\rho$.

Assume that $\omega$ is not a single parameter. Then, we have an interval of parameters with a superattracting periodic cycle. Therefore, the critical point $c = 1$ is periodic in this interval of parameters, i.e. $B_{2,3a}(1) = 1$ for all parameters $(2, 3\alpha) \in \omega$. This is impossible since $B_{2,\alpha}$ is strictly increasing with respect to $\alpha$ (see lemma 2.5). Hence, $\omega$ is a single parameter $r_\tau = \lim_{\rho \to 0} a(\rho)$. Notice also that this parameter has type $\tau$. Indeed, given the fact that it has
a superattracting periodic point, it belongs to a tongue of type $\tau'$. Since tongues are open sets in $\mathbb{C} \setminus \mathbb{D}_2 = \{ a \mid |a| > 2 \}$, we conclude that any curve of parameters contained in $\mathbb{C} \setminus \mathbb{D}_2$ and landing in $\omega$ necessarily intersects $T$. We conclude that $\tau' = \tau$ since $a(\rho)$ have type $\tau$ for all $\rho \in (0, 1)$ by lemma 3.12.

In order to finish the proof of statements (a) and (b) of theorem A we have to show that the limit does not depend on the initial parameter $a \in T$. We use the following lemma.

**Lemma 3.13.** Let $g_\alpha(x) := B_{2, \log}(x)$, $x \in \mathbb{S}$. Then, for any $p \in \mathbb{N}$, the mapping $\alpha \rightarrow g_\alpha^p(1) \in \mathbb{S}$, $\alpha \in [0, 1/3)$, is strictly increasing and of degree $2^p - 1$.

**Proof.** The map $\alpha \rightarrow g_\alpha^p(1)$ is increasing by lemma 2.5. We only have to prove that $\alpha \rightarrow g_\alpha^p(1)$ has degree $2^p - 1$. The lift of $g_\alpha$ is given by

$$h_\alpha(x) = 3x + 3\alpha + \frac{1}{2\pi} \log \left( \frac{e^{2\pi i x} - 2}{1 - 2e^{2\pi i x}} \right).$$

The result is true for $p = 1$ in the sense that $h_{\alpha + 1/3}(x) = h_\alpha(x) + 1$. By induction over $p$ and using that $h_\alpha^p(x + 1) = h_\alpha^p(x) + 2^p$ ($g_\alpha$ has degree two as a circle map) we have

$$h_{\alpha + 1/3}^{p+1}(x) = h_{\alpha + 1/3}^p(h_{\alpha + 1/3}(x)) = h_{\alpha + 1/3}^p(h_\alpha(x) + 1) = h_{\alpha + 1/3}^p(h_\alpha(x)) + 2^p = h_\alpha^{p+1}(x) + 2^p - 1 + 2^p - 1.$$

It follows from this lemma that $g_\alpha^p$ has exactly $2^p - 1$ parameters $\alpha, \alpha \in (0, 1/3)$, such that the critical point is periodic of period dividing $p$. Indeed, for every natural $k \in \{0, 1, ..., 2^p - 2\}$, there exists a unique $\alpha_{p,k} \in [0, 1/3)$ such that $h_{\alpha_{p,k}}^p(0) = 0 + k$. It can be computed using the expression of the semiconjugacy $H_\alpha$ (see lemma 3.1) that a parameter $\alpha_{p,k} = 2e^{2\pi ikp}$ has type $\tau(\alpha_{p,k}) = k(2^p - 1)$ (see [Dez10, lemma 4.2]). Since the expression in the form $k(2^p - 1)$ of a periodic point $\tau$ of period $p$ of the doubling map is unique, we conclude that, for a fixed type $\tau$, there exists a unique parameter $\alpha_{p,k} \in (0, 1/3)$ which has a superattracting cycle of type $\tau$. Hence, we can also conclude that no tongue $T_{\tau,p}$ is empty. It also follows from this that the limit $\omega$ is unique up to conjugacy since, for a fixed type $\tau$, there exists a unique possible limit. This finishes the proof of statements (a) and (b) of theorem A.

**Remark 3.14.** We have not proven that the three connected components of a tongue $T_{\tau,p}$ are actually different. A priori a tongue $T_{\tau,p}$ could have a single connected component that would contain the three symmetric roots. However, this is not possible due to the description of the boundaries of the tongues given by statement (d) of theorem A (see theorem 3.25), whose proof is independent of the one of statements (a) and (b).

### 3.2. Boundary of the tongues: proof of statements (c) and (d) of theorem A

The goal of this section is to prove statements (c) and (d) of theorem A (see [MR07, MR08]). In order to do so we describe the boundary of the tongues and the parameters therein. The following is a direct consequence of lemma 2.5, which states that there cannot be any attracting periodic cycle in $\mathbb{S}$ if $|a| \geq 3$.

**Proposition 3.15.** If $a \in T$, then $|a| < 3$. Consequently, tongues are bounded.

The following result is a corollary of lemma 3.4, which states that a parabolic cycle of $B_{|\log|}$ can have at most one periodic petal intersecting $\mathbb{S}$. 

3479
Then, there exists a sequence of parameters \(\alpha_0, \alpha_1, \ldots, \alpha_n\) such that \(x_0 \in \tau_\alpha\), \(x_n\) is a homeomorphism, the endpoints of \(J\) are fixed points of \(x_0\). Then, either \(J\) is a connected closed interval or it consists of the same point as \(x\) does not belong to it. Finally, we say that \(r, \alpha\) does not belong to it. Conversely, \(1, \alpha\) belongs to the tongue and \(r, \alpha\) belongs to the left boundary of the tongue.

**Corollary 3.16.** A parabolic cycle \((x_0) \in \mathbb{S}\) of \(B_a\) \(|a| > 2\), cannot be attracting from both sides in \(\mathbb{S}\). More precisely, if \(x_0\) is a parabolic fixed point of \(B_a\), there cannot exist a neighborhood \(U\) of \(x_0\) in \(\mathbb{S}\) such that all the points \(U\) are attracted to \(x_0\) under iterations of \(B_a\).

The next lemma states that parameters on the boundary of tongues correspond to maps having parabolic cycles.

**Lemma 3.17.** If \(a\) belongs to the boundary of a tongue, then \(B_a\) has a parabolic cycle of multiplier 1.

**Proof.** Let \(a_0 \in \partial T_1\). Then, there exists a sequence of parameters \(a_n \in T_1, n \in \mathbb{N}\), such that \(a_n\) accumulate on \(a_0\). Let \(x_n\) be the attracting periodic point of \(B_{a_n}\) having the critical points in its immediate basin of attraction. Since \(\mathbb{S}\) is compact, we may assume that \(x_n\) converge to a point \(x_0 \in \mathbb{S}\). Since \(B_{a_n}\) depends continuously on \(a\), we conclude that \(x_0\) is a periodic point of \(B_{a_0}\). The multiplier of \(x_0\) has to be 1. Indeed, it is real since \(x_0 \in \mathbb{S}\), it is positive since \(B_{a_0}\) is increasing and it cannot be smaller than 1 because otherwise would belong to the interior of a tongue \(T_1\), which is impossible since tongues are disjoint.

From now on it will be convenient to work with the alternative parametrization of the Blaschke family \(g_{r,\alpha} := B_{3\alpha}^{-1}\) as in section 2.1. We consider the parameter space \((r, \alpha)\) with \(r \geq 2\) and \(\alpha \in \mathbb{R}/\mathbb{Z}\) instead of \(a \in \mathbb{C}\) with \(|a| > 2\). The main reason to use this alternative parametrization is to use the monotonicity with respect to \(\alpha\) given by lemma 2.5.

**Definition 3.18.** We say that a parameter \((r_0, \alpha_0)\), \(r_0 > 2\), in a boundary of a tongue \(T_\alpha\) of period \(p\) belongs to the left boundary of the tongue if there exists an \(\epsilon > 0\) such that, for all \(0 < \alpha < \epsilon\), \((r_0, \alpha + \epsilon)\) belongs to the tongue and \((r_0, \alpha - \epsilon)\) does not belong to it. Conversely, we say that it belongs to the right boundary if there exists an \(\epsilon > 0\) such that, for all \(0 < \alpha < \epsilon\), \((r_0, \alpha)\) belongs to the tongue and \((r_0, \alpha + \epsilon)\) does not belong to it. Finally, we say that it belongs to a tip of the tongue if there exists an \(\epsilon > 0\) such that, for all \(\alpha \in (-\epsilon, 0) \cup (0, \epsilon)\), \((r_0, \alpha + \epsilon)\) does not belong to the tongue.

Using lemma 2.5, we have the following result (see [MR07, lemma 4.1]).

**Lemma 3.19.** Let \(x_0\) be an attracting or parabolic periodic point of \(g_{r_0,\alpha_0}\) of period \(p\) and let \(H_{r_0,\alpha_0}\) be the semiconjugacy between \(g_{r_0,\alpha_0}\) and the doubling map given by lemma 3.1. Let \(J\) be the set of points \(x \in \mathbb{S}\) which are sent by \(H_{r_0,\alpha_0}\) to the same point as \(x_0\), i.e. \(J = \{x \mid H_{r_0,\alpha_0}(x) = H_{r_0,\alpha_0}(x_0)\}\). Then, either \(J\) is a connected closed interval or it consists of a single point. Moreover, \(g_{r_0,\alpha_0}\) is a homeomorphism, the endpoints of \(J\) are fixed points of \(g_{r_0,\alpha_0}\) and one of the following holds (see figure 4).

(a) \(J\) is an interval. The left endpoint of \(J\) is parabolic, topologically attracting from the right and repelling from the left, the right endpoint is repelling and there are no other fixed points of \(g_{r_0,\alpha_0}\) in \(J\). In this case \((r_0, \alpha_0)\) belongs to the left boundary of the tongue.

![Figure 4](image-url)
(b) $J$ is an interval. The right endpoint of $J$ is parabolic, topologically attracting from the left and repelling from the right, the left endpoint is repelling and there are no other fixed points of $g^p_{r_0,\alpha_0}$ in $J$. In this case $(r_0, \alpha_0)$ belongs to the right boundary of the tongue.

(c) $J$ is an interval. Both endpoints of $J$ are repelling, there is an attracting fixed point of $g^p_{r_0,\alpha_0}$ in $J$ and there are no other fixed points of $g^p_{r_0,\alpha_0}$ in $J$. In this case $(r_0, \alpha_0)$ belongs to the interior of the tongue.

(d) $J$ consists of a parabolic periodic point which is topologically repelling in $S^1$.

**Proof.** Throughout the proof we consider the points of $S^1$ oriented anticlockwise. The fact that $J$ is either a single point or a closed interval follows since $H_{r_0,\alpha_0}$ is an increasing continuous function (see lemma 3.1). Since $g^p_{r_0,\alpha_0}|J$ is an strictly increasing function (see lemma 2.5), we have that $g^p_{r_0,\alpha_0}|J$ is a local homeomorphism around each point. It follows that $g^p_{r_0,\alpha_0}|J$ is a homeomorphism and its endpoints are fixed points of $g^p_{r_0,\alpha_0}$.

It follows from lemma 3.4 and corollary 3.16 that only these four cases can occur. Lemma 3.4 states that $g^p_{r_0,\alpha_0}|J$ can have at most one attracting or parabolic cycle whilst corollary 3.16 states that a parabolic cycle cannot be topologically attracting from both sides.

It is left to see that case (a) corresponds to the left boundary of the tongue whereas case (b) corresponds to the right boundary. We prove it for case (a). Case (b) is analogous.

Assume that $(r_0, \alpha_0)$ satisfies the hypothesis of case (a). Then, there exists a periodic point of period $p$ which is repelling from the left and attracting from the right. Recall that, from lemma 2.5, we have that $g^p_{r_0,\alpha_0}$ is strictly increasing with respect to $\alpha$ for any $p \in \mathbb{N}$.

We first prove that there exists an $\epsilon > 0$ such that if $0 < \alpha < \epsilon$, then $g^p_{r_0,\alpha_0}$ has an attracting cycle of period $p$. Let $x$ be a point of the parabolic cycle and let $y$ be a point in the immediate basin of attraction of $x$. Then $x < y$ and $g^p_{r_0,\alpha_0}(y) < y$. Since $g^p_{r_0,\alpha_0}$ is strictly increasing with respect to $\alpha$, there exists an $\epsilon > 0$ such that if $0 < \alpha < \epsilon$, then $g^p_{r_0,\alpha_0}(x) > x$ and $g^p_{r_0,\alpha_0}(y) < y$. Hence, there has to be a topologically attracting periodic point of period $p$ between $x$ and $y$.

Since, by corollary 3.16, a parabolic periodic point cannot be attracting from both sides, we get that this topological attractor located between $x$ and $y$ is an attractor.

Now we have to see that there exists an $\epsilon > 0$ such that if $0 < \alpha < \epsilon$, then $g^p_{r_0,\alpha_0}$ has no periodic attracting cycles of period $p$. Since $x$ is repelling from the left and attracting from the right, there exists a $\delta > 0$ such that if $y \in (x - \delta, x + \delta)$, then $g^p_{r_0,\alpha_0}(y) \not\in J$. Using that $g^p_{r_0,\alpha_0}$ is strictly increasing with respect to $\alpha$, we can take $\epsilon_1 > 0$ such that if $0 < \alpha < \epsilon_1$, then $g^p_{r_0,\alpha_0}(y) < y$ for all $y \in (x - \delta, x + \delta)$. Doing the same around all of the points $x_m$ of the parabolic cycle we obtain $\delta' > 0$ and $\epsilon_2 > 0$ such that if $0 < \alpha < \epsilon_2$, then $g^p_{r_0,\alpha_0}(y) < y$ for all $y \in (x_m - \delta', x_m + \delta')$. Hence, we have erased the periodic points of period $p$ in a $\delta'$-neighborhood $U$ of our cycle. Since $g^p_{r_0,\alpha_0}$ has finitely many fixed points in $S^1 \setminus U$, all of them repelling, we can take $\epsilon_3 < \epsilon_2$ such that if $0 < \alpha < \epsilon_3$, then $g^p_{r_0,\alpha_0}$ has no attracting fixed point at all.

We want to prove that case (d) of lemma 3.19 corresponds to a tip of the tongue (see proposition 3.22). We first introduce some auxiliary results.

**Theorem 3.20 ([MR08, theorem 3.2]).** Let $U$ be a neighborhood of the origin in $\mathbb{R}^2$ and let $F : U \to \mathbb{R}$ be a real analytic function. Set $f_0(x) = F(t, x)$. Assume that $f_0$ has a topologically repelling fixed point at $x = 0$ and that

$$\frac{\partial F}{\partial t}(0, 0) \neq 0.$$

3481
Then there are open intervals $I, J$ containing 0 such that $I \times J \subset U$ and for every $t \in I$ the map $f_t$ has exactly one fixed point $x \in J$. Moreover, if $t = 0$, then this fixed point is (differentially) repelling.

We use the previous theorem in the following result.

**Lemma 3.21.** Consider a one parameter subfamily $f_t = g_{\alpha(t),0\alpha}$ of the Blaschke family such that $r(t)$ and $\alpha(t)$ depend analytically on $t$. Assume that $f^p_t$ has a topologically repelling parabolic fixed point $x_0$ and $G(t,x) = f^q_t(x)$. Then there exists $\epsilon > 0$ such that if $t \in (-\epsilon,0) \cup (0,\epsilon)$ then $f^p_t$ has no attracting or parabolic fixed point.

**Proof.** By theorem 3.20, there exists $\epsilon_1 > 0$ and a neighborhood $U_1$ of $x_0$ such that if $t - t_0 \in (-\epsilon_1,0) \cup (0,\epsilon_1)$, then $f^p_t$ has no attracting or parabolic fixed point in $U_1$. Now, as in proof of lemma 3.19, we can perform the same argument around the other $p - 1$ points of the parabolic cycle, obtaining an $\epsilon_2 > 0$ and a neighborhood $U$ of $\{x_0, \ldots, x_{p-1}\}$ such that if $t - t_0 \in (-\epsilon_2,0) \cup (0,\epsilon_2)$ then $f^p_t$ has no attracting or parabolic fixed point in $U$. Since $f^p_t$ has only finitely many fixed points in $\mathbb{S}_1 \setminus U$, all of them repelling, we can take $\epsilon_3 < \epsilon_2$ such that if $t - t_0 \in (-\epsilon_3,0) \cup (0,\epsilon_3)$ then $f^p_t$ has no attracting or parabolic fixed point at all.

This result gives us directly the following proposition.

**Proposition 3.22.** A parameter $(r,\alpha)$ in a boundary of a tongue for which case (d) of lemma 3.19 occurs, is a tip of that tongue.

From lemma 3.19 and proposition 3.22 we obtain the next corollary.

**Corollary 3.23.** Any parameter $(r_0,\alpha_0)$ of the boundary of a tongue $\tau_T$ either belongs to the right or to the left boundary of the tongue or is a tip of the tongue.

The next result is another corollary of lemma 3.21.

**Lemma 3.24.** The boundary of a tongue cannot be flat for any $r_0$, i.e. given any tongue $\tau_T$ and $r_0 > 2$ the intersection of $\partial \tau_T$ with the circle of parameters $|a| = r_0$ cannot contain intervals of parameters.

**Proof.** Assume that such interval exists. Then its parameters cannot belong to the left boundary or the right boundary by definition. Hence, the parameters of this interval are tips of the tongue. Therefore, we would have an $\epsilon > 0$ such that $B_{r_0,\alpha},0\alpha$ has a topologically repelling parabolic fixed point for all $|\alpha| < \epsilon$ and for some $\alpha_0$. However, this would contradict lemma 3.21.

We now prove the remaining statements of theorem A. The following theorem proves statement (c).

**Theorem 3.25.** Given $r_0 \geq 2$, the intersection of any connected component of a tongue $\tau_T$ with the parameter circle $|a| = r_0$ is connected. In particular, every connected component of a tongue is simply connected.

**Proof.** Assume that the intersection of a connected component of a tongue $\tau_T$ with the parameter circle $|a| = r_0$ is not connected. Then either the boundaries have a local maximum, or have a local minimum, or the tongue is not simply connected. Since by lemma 3.24 the boundary of a tongue can be nowhere flat, there exists a parameter $(r_1,\alpha_1)$ and $\epsilon > 0$ such that, for any $\alpha \in (-\epsilon,0) \cup (0,\epsilon)$, the parameter $(r_1,\alpha_1 + \alpha)$ belongs to the tongue (see figure 3).
That would imply that \((r_1, \alpha_1)\) is a parameter in the boundary of \(T_c\) which does not belong to the right or left boundary and which is not a tip of the tongue, contradicting corollary 3.23. □

Finally, we prove statement (d).

**Proof of statement (d).** It follows from theorem 3.25 that the left and right boundaries are well defined curves. Both the left and the right boundary begin in two different parameters \(a_-\) and \(a_+\) with \(|a_-| = 2 = |a_+|\). Both boundaries are bounded by proposition 3.15 and hence they have to end at a point where they intersect, which is a tip. This finishes the proof since by lemma 3.24 the boundary of a tongue cannot be flat for any \(r_0\) and by theorem 3.25 neither the left nor the right boundaries can have local maximums.

### 4. Bifurcations around the tip of the tongues: proof of theorem B

In this section we study the bifurcations which occur throughout the boundaries of the tongues. Given a tongue \(T_c\), there is a persistent saddle-node bifurcation which takes place along \(\partial T_c \setminus a_-\); two cycles collide in \(\mathcal{S}\) and exit it (see figure 6). The goal of the section is to prove theorem B, that is, to study the bifurcations in a neighbourhood of the tip of the tongues and to see that, if the parameter is close enough to a tip, the two cycles leaving the unit circle are attracting.

The proof of theorem B uses proposition 4.7. Before stating the result, we introduce the concepts of algebraic geometry used on its proof. For a more detailed introduction to the topic we refer to [Har77] and [Sha13]. First of all we recall the definition of algebraic variety in \(\mathbb{C}^n\).

**Definition 4.1.** Let \(\mathbb{C}[z_1, \ldots, z_n]\) be the polynomial ring of \(n\) variables over \(\mathbb{C}\). A subset \(Y \subset \mathbb{C}^n\) is said to be an affine algebraic variety if there exists a finite set of polynomials \(S \subset \mathbb{C}[z_1, \ldots, z_n]\) such that \(Y = \{w \in \mathbb{C}^n \mid f(w) = 0 \text{ for all } f \in S\}\).

It is also useful to consider algebraic sets in the projective space \(\mathbb{P}_\mathbb{C}^n\). In this setting we work with homogeneous polynomials \(f \in \mathbb{C}[z_0, \ldots, z_n]\) of degree \(d\). Therefore, if \(a \in \mathbb{C}^{n+1}\) and \(\lambda \in \mathbb{C}\), then \(f(\lambda a) = \lambda^d f(a)\) and the sets of zeros on \(\mathbb{P}_\mathbb{C}^n\) are well defined.

**Definition 4.2.** A subset \(Y \subset \mathbb{P}_\mathbb{C}^n\) is said to be a projective algebraic variety if there exists a finite set of homogeneous polynomials \(S \subset \mathbb{C}[z_0, \ldots, z_n]\) such that \(Y = \{w \in \mathbb{P}_\mathbb{C}^n \mid f(w) = 0 \text{ for all } f \in S\}\).

Affine varieties can be seen as subsets of projective varieties. Indeed, given polynomial \(f \in \mathbb{C}[z_1, \ldots, z_n]\), it is not difficult to obtain a homogeneous polynomial \(F \in \mathbb{C}[z_0, \ldots, z_n]\)
such that if \( w = (w_1, ..., w_n) \in \mathbb{C}^n \) satisfies \( f(w) = 0 \), then \( w' = [1 : w_1 : \cdots : w_n] \in \mathbb{P}_\mathbb{C}^n \) satisfies \( F(w') = 0 \). The Euclidean topology is not convenient when working with algebraic varieties. We shall work with the Zariski topology instead.

**Definition 4.3.** The Zariski topology on \( \mathbb{C}^n \) or \( \mathbb{P}_\mathbb{C}^n \) is defined as the topology whose open sets are the complements of algebraic varieties.
The Zariski topology is well defined since the finite union and intersection of algebraic varieties are algebraic varieties and the empty set and $\mathbb{C}^n$ (or $\mathbb{P}^n$) are also algebraic varieties. Using this topology we can introduce the concepts of constructible sets and quasiprojective varieties.

**Definition 4.4.** A set $A$ is **locally closed** if it is the intersection of an open and a closed subsets of $\mathbb{C}^n$ (or $\mathbb{P}^n$). A set is said to be **constructible** if it is a finite disjoint union of locally closed sets.

**Definition 4.5.** A quasiprojective variety is a locally closed subset of an algebraic variety, i.e. the intersection of an algebraic variety with an open set of the Zariski topology.

Notice that, by definition, quasiprojective varieties are constructible sets. We finish this introduction to algebraic geometry presenting a simplified version of Chevalley’s theorem (see [Gro67], [Har77, exercise 3.19]), which is the main result we use on the proof of proposition 4.7.

**Theorem 4.6 (Chevalley’s theorem).** Any morphism of quasiprojective varieties sends constructible sets to constructible sets.

We have not defined what a morphism of quasiprojective varieties is. However, we want to remark that we apply Chevalley’s theorem to the map given by the projection over one of the components of the variety, which is indeed a morphism of quasiprojective varieties.

Now we can state and prove proposition 4.7.

**Proposition 4.7.** For fixed $n > 0$, there is only a finite number of parameters $a \in \mathbb{C}$ for which the Blaschke product $B_a$ has a parabolic cycle of exact period $n$, multiplier 1 and multiplicity 3.

**Proof.** It will be convenient to work with the alternative parametrizations of the Blaschke products $B_a$ presented in section 2.1. Recall that, if $a = re^{\alpha i}$ with $r > 0$ and $\alpha \in \mathbb{R}$, $B_a$ is conjugate with $B_{r, \alpha}$ (equation (2)). The Blaschke products $B_{r, \alpha}$ are embedded within the family $G_{a,b}$ (equation (7)), where $a, b \in \mathbb{C}$. We will prove that, for fixed $n > 0$, there is only a finite number of parameters $(a, b)$, where $a, b \in \mathbb{C}$, for which $G_{a,b}$ has a parabolic cycle of exact period $n$, multiplier 1 and multiplicity 3.

We first show that the immediate basin of attraction of such a cycle contains both free critical points. Indeed, a parabolic cycle $\{z_0\}$ of exact period $n$, multiplier 1 and multiplicity 3 has two disjoint cycles of maximal attracting petals attached to it (see [Mil06, theorem 10.7] and figure 6(a)). Each of these cycles of maximal petals has at least one critical point on the boundary of one of its components (see [Mil06, theorem 10.15]). Therefore, the immediate basin of attraction of $\{z_0\}$ contains both free critical points of $G_{a,b}$. Notice also that it follows from this assumption that the multiplicity cannot be greater than 3 since the rational maps $G_{a,b}$ only have two free critical points.

Parameters which satisfy the hypothesis are solutions of the system of rational equations

$$\begin{cases}
G_{a,b}^n(z) = z, \\
\frac{\partial G_{a,b}^n}{\partial z}(z) = 1, \\
\frac{\partial^2 G_{a,b}^n}{\partial z^2}(z) = 0.
\end{cases}$$

(8)

Take the polynomials $p_1(z, a, b), p_2(z, a, b), p_3(z, a, b)$ and $q(z, a, b)$ so that the previous system reduces to
\[
\begin{align*}
\begin{cases}
p_1(z, a, b)q(z, a, b) &= z, \\
p_2(z, a, b)/q(z, a, b)^2 &= 1, \\
p_3(z, a, b)q(z, a, b)^3 &= 0.
\end{cases}
\end{align*}
\]

Notice that \(p_2\) and \(p_3\) are combinations of \(p_1\), \(q\) and their derivatives. We obtain the polynomial system of equations
\[
\begin{align*}
\begin{cases}
p_1(z, a, b) - zq(z, a, b) &= 0, \\
p_2(z, a, b) - q(z, a, b)^2 &= 0, \\
p_3(z, a, b) &= 0.
\end{cases}
\end{align*}
\]

(9)

The solutions of (8) also solve (9). However, we have added solutions. They come from points \((z, a, b)\) on which either the numerator and the denominator vanish simultaneously or are both equal to infinity. They can be equal to infinity if and only if \(z = \infty\) or \(a = \infty\) or \(b = \infty\). Such points are not solutions of the original system. The point \(z = \infty\) is a permanent superattracting fixed point (unless \(b = 0\) or \(b = \infty\)) and, therefore, does not satisfy the equations of a parabolic point. If \(a = \infty\) then \(G_{a,b}(z)\) degenerates to \(bz^2\), which does not have parabolic cycles. If \(b = \infty\) then \(G_{a,b}\) is constant and therefore does not have any parabolic cycle. The points for which the numerator and the denominator vanish simultaneously come from the system
\[
\begin{align*}
\begin{cases}
p_1(z, a, b) &= 0, \\
q(z, a, b) &= 0.
\end{cases}
\end{align*}
\]

(10)

Notice that, if \(q(z, a, b) = 0\) but \(p_1(z, a, b) \neq 0\) then the first equation in (9) is not satisfied and, therefore the point \((z, a, b)\) is not a solution. Assume that \((z, a, b)\) solves (10). Then there is a \(z_0\) such that the numerator and the denominator of
\[
bG_{a,b}^{-1}(z_0)^3 \frac{G_{a,b}^{-1}(z_0) - a}{1 - aG_{a,b}^{-1}(z_0)}
\]
vanish simultaneously. This can only happen if \(b = 0\) or \(a = \pm 1\). If \(b = 0\) the map \(G_{a,b}\) is constant and therefore (8) has no solution. If \(a = \pm 1\) the family \(G_{a,b}(z)\) degenerates to the polynomials \(\pm b^3\) and the system (8) has no solution.

We also assumed that the parabolic cycle has exact period \(n\). Thus, the parameters which satisfy the hypothesis of the lemma are such that the equality
\[
G_{a,b}^m(z) = z
\]
(11)
is not satisfied for any \(m < n\). If \(G_{a,b}^m(z) = \tilde{p}_m(z, a, b)\tilde{q}_m(z, a, b)\), the set of points which satisfy the previous equality, are solutions of the polynomial equation
\[
\tilde{p}_m(z, a, b) - z\tilde{q}_m(z, a, b) = 0.
\]

(12)

The set of solutions of (9) is an algebraic variety, say \(Y\). Each point of \(Y\) is either solution of (8) or corresponds to any of the degeneracy situations already described. The set of solutions of (12) consists of the solutions of (11) and exactly the same degeneracy solutions described for (9). Let \(Y'\) be the quasiprojective variety obtained by intersecting \(Y\) with the open set of the Zariski topology given by \(b \neq 0, b \neq \infty, a \neq \pm 1, a \neq \infty, z \neq \infty\) and \(\tilde{p}_m(z, a, b) - z\tilde{q}_m(z, a, b) \neq 0\) for all \(m < n\). If \((z, a, b)\) belongs to \(Y'\) then it is a solution of (8) and does not solve (11). Therefore, \((z)\) is a parabolic cycle of \(G_{a,b}\) of period exactly \(n\), multiplier 1 and multiplicity 3 whose immediate basin of attraction contains both free critical orbits.

J Canela et al

Nonlinearity 29 (2016) 3464
Since by lemma 2.6 the non-escaping set is bounded in $a$, we conclude that the projection of $Y'$ over the variable $a$ is bounded. It follows from Chevalley’s theorem (theorem 4.6) that the projection of a quasiprojective variety over a variable is a constructible set. We conclude that the projection of $Y'$ over $a$ is finite since constructible sets in $\mathbb{C}$ are either dense in $\mathbb{C}$ or finite. Summarizing we have that there are finitely many $a$ for which (8) has solution.

Finally, consider the previous equation systems with $a_0 = 1$ fixed. Let $Y'$ be the quasiprojective variety of points $(z, a_0, b)$ which solve (8), do not solve (12) for any $m < n$ and the degeneracy conditions are not satisfied. By lemma 2.7 we know that, for fixed $a_0 = 1$, the non-escaping set is bounded on $b$. As before we conclude that $Y'$ projects onto a finite number of $b$, which finishes the proof.

Notice that the condition of having exactly period $n$ on the previous proposition is necessary. Indeed, the family $B_a$ has curves of parabolic parameters whose parabolic cycle $(z_0)$ of period $n$ has multiplier $-1$ (see theorem C). The point $z_0$ is also a parabolic fixed point of $B_a^{2n}$ of multiplier 1 and multiplicity 3. Therefore, if we do not require exact period $n$ then we may obtain infinitely many solutions of (8).

We now prove theorem B, which tells us that there is a neighborhood $U$ of the tip of any tongue such that if $a \in U$ then either $a$ belongs to the tongue, or to its boundary, or $B_a$ has two disjoint attracting cycles (see figures 6(a), (b), (d) and 7).

**Proof of theorem B.** The main ingredient for the proof is the holomorphic index. Given a fixed point $z_0$ of a holomorphic function $f$, the holomorphic fixed point index of $z_0$, denoted by $i(z_0)$, is defined to be the residue of $l(z - f(z))$ around $z$. If the fixed point has multiplier $\rho \neq 1$, then $i(z_0) = 1/(1 - \rho)$ (see [Mil06]). Moreover, when $n$ different fixed points collide in a parabolic point $z_0$ of multiplier 1, their indexes tend to infinity, even if the sum of their indexes tends to the finite index $i(z_0)$ of the parabolic point.

Let $(w_0)$ be the parabolic cycle of $B_a$. Then, $w_0$ is a parabolic periodic point of multiplier 1, multiplicity 3 and exact period $p$ of $B_a$. Since, by proposition 4.7, there is a finite number of such parameters, it follows that there is an open neighborhood of the parameter $a$, which contains no other parameter $a'$ for which $B_{a'}$ has a parabolic cycle of multiplier 1, multiplicity 3 and the same period than $(w_0)$. Take a parameter $a$ close to $a$. The map $B_a^p$ has three fixed points, say $z_0$, $z_+$, and $z_-$, which tend to $w_0$ when $a$ tends to $a$. By symmetry and continuity of the semiconjugacy $H_a(x)$ with respect to $a$ and $x$, at least one of the fixed points lies in $\mathbb{S}$, say $z_0$, and satisfies $H_a(z_0) = \tau$. Also by symmetry, if more than one fixed point lies in $\mathbb{S}$, the three of them do. In that later case, since $B_a^{2p}$ is strictly increasing, one of them is either parabolic or attracting and satisfies $H_a(z) = \tau$ by continuity of $H_a$, so either belongs to the tongue $T_a$ or its boundary. Assume that only $z_0$ lies in $\mathbb{S}$ and is repelling (if it was attracting it would belong to $T_a$ again by continuity of $H_a$). Then $z_0$ has real multiplier $\eta > 1$ (compare lemma 3.4). Due to the symmetry, the other two fixed points, $z_+$, are symmetric. Moreover, their multipliers are complex conjugate say $\rho$ and $\overline{\rho}$. Indeed, we can conjugate $B_a$ via a Möbius transformation $M$ to a rational map $B_{a'}$ that fixes the real line. The assertion follows then from the fact that $B_{a'}(z) = B_a(z)$ and that $M$ preserves the multiplier of the periodic cycles.

Consider the sum $S$ of the indexes of the three periodic points,

$$S = i(z_0) + i(z_+) + i(z_-) = \frac{1}{1 - \eta} + \frac{1}{1 - \rho} + \frac{1}{1 - \overline{\rho}}.$$

The number $S$ is a real quantity which tends to the index of the parabolic cycle of the tip of the tongue whenever $a$ tends to $a$. Moreover, $i(z_0)$ tends to minus infinity when $a$ tends to $a$. 

3487
Hence, there is an open neighborhood $U$ of $a_0$ such that if $a \in U$ then $\tilde{S} = S - i(z_0) > 1$. Write $\rho = 1 + \epsilon = 1 + \epsilon_1 e^{i\epsilon_1} e, \epsilon \in \mathbb{R}$. Then, if $a \in U$, we have

$$\tilde{S} = \frac{1}{1 - 1 - \epsilon} + \frac{1}{1 - 1 - \epsilon} = -\frac{2\epsilon}{|\epsilon|^2}.$$ 

It follows from this equation that, if $a \in U$, then $\epsilon < 0$. Finally, using that $|\epsilon|^2 = -2\epsilon/\tilde{S}$, we have

$$|\rho|^2 = (1 + \epsilon)^2 + \epsilon^2 = 1 + 2\epsilon - \frac{2\epsilon}{\tilde{S}} = 1 + 2\epsilon_1 \left(1 - \frac{1}{\tilde{S}}\right).$$

Since $\epsilon < 0$ and $\tilde{S} > 1$ we conclude that $|\rho| < 1$, which finishes the proof. 

We finish the section showing some consequences of the construction presented in the proof of theorem B. The next corollary follows from the previous theorem and statement (d) of theorem A, which states that the boundary of any tongue corresponds to the union of two arcs which intersect at the tip of the tongue. These two arcs can be parametrized univalently with respect to the modulus of the parameter.

**Corollary 4.8.** Given a tongue $T_\tau$, there exists a hyperbolic component of $B_\alpha$ of disjoint type sharing part of its boundary with $T_\tau$ in a neighborhood of the tip $a_0$.

The following proposition tells us that all parameters $\alpha$, with $|\alpha| > 2$, such that $B_\alpha$ has a parabolic cycle which is topologically repelling in the unit circle are tips of tongues.

**Proposition 4.9.** If $|a_0| > 2$ and $B_\alpha$ has a parabolic cycle of multiplicity 3 and exact period $n$ in the unit circle then $a_0$ is the tip of a tongue of period $n$.

**Proof.** Assume that $a_0$ is not a tip of a tongue of period $n$. Then the same perturbation done in the proof of theorem B can be performed, obtaining a disjoint hyperbolic component of parameters which surrounds $a_0$. Indeed, since $a_0$ is not in the boundary of a tongue of period $n$ and there is a finite number of parameters with a parabolic cycle of multiplier 1, multiplicity 3 and exact period $n$ by proposition 4.7, the perturbation presented in the proof of theorem B gives us an open neighborhood $U$ of $a_0$ such that if $a \in U$, $a \neq a_0$, then the Blaschke product $B_\alpha$ has two disjoint attracting cycles other than $z = 0$ and $z = \infty$. Therefore, the set of parameters

![Figure 7. A zoom in on a neighborhood of the tip $a_0$ of the tongue $T_\tau$. The colors are as in figure 2. We see in orange the fixed tongue $T_0$ and in pink a disjoint hyperbolic component which partially shares the boundary with $T_0$.](image_url)
U would be contained in a multiply connected disjoint hyperbolic component whose attracting cycles are not in the unit circle, which is impossible by theorem 2.4.

\[\square\]

**Corollary 4.10.** If \(|a| > 2\) and \(B_a\) has a parabolic cycle on the unit circle, then \(a\) belongs to the boundary of a tongue.

**Proof.** If the parabolic cycle of \(B_a\) has multiplicity 2 then it is on the boundary of a period \(n\) tongue by lemma 3.19. If it has multiplicity 3 it is on the tip of a fixed tongue by proposition 4.9.

\[\square\]

### 5. Extended tongues

The goal of this section is to give an idea of the dynamics that may take place for parameters within the open annulus \(A_{1,2}\) of inner radius 1 and outer radius 2. The section is structured as follows. We first notice that the tongues studied up to this point may be extended within this annulus. Then we describe more precisely how the fixed tongue extends. Finally we do some numerical computations to obtain an idea of other phenomena which may take place.

The definition of tongues only makes sense for parameters \(a\) such that \(|a| \geq 2\). However, given a tongue \(T_c\), its attracting cycle \((z_0)\) can be analytically continued for parameters \(1 < |a| < 2\) (see figure 8), parameters for which \(B_{\text{alg}}\) is not a degree 2 cover of the unit circle (see section 2) and, therefore, is not semiconjugate to the doubling map. We proceed to formally define the concept of extended tongue using the analytic continuation of the attracting cycle.

**Definition 5.1.** An extended tongue \(ET_c\) is defined to be the set of parameters for which the attracting cycle of \(T_c\) can be continued analytically. More precisely, we say that a parameter \(a\) belongs to the extended tongue \(ET_c\) (of period \(p\)) if \(1 < |a|\), \(B_{\text{alg}}\) has an attracting periodic point of period \(p\) and there exists a curve of parameters \(\gamma(t)\) such that \(\gamma(0) = a, \gamma(1) \in T_c\) and \(B_{\text{alg}}\) has an attracting fixed point of period \(p\) for all \(t \in (0, 1)\) which depends continuously on \(t\).

![Image](https://via.placeholder.com/150)
Since the set of hyperbolic parameters is open in $\mathbb{C}$ and the roots of the tongues (parameters for which the cycle is superattracting) have modulus equal to 2 (see theorem A) we conclude that $\mathcal{T} \cap \Lambda_{1,2}$ is not empty for any periodic point $\tau$ of the doubling map. Notice that, with the previous definition, parameters $a \in T$ also belong to $\mathcal{T}$. The following lemma describes the parameters on the boundary of the extended tongues. Its proof is analogous to the one of lemma 3.17.

**Lemma 5.2.** If $a$ belongs to the boundary of an extended tongue and $|a| \neq 1$, then $B_a$ has a parabolic periodic point of multiplier $\pm 1$.

Notice that the intersection of two different extended tongues might be a non empty open set. Indeed, the critical orbits are not symmetric if $a \in \Lambda_{1,2}$. Because of that, for $1 < |a| < 2$, $B_{a/\alpha}$ might have two different attracting cycles, in which case $a$ might belong to two different tongues (see figure 8).

### 5.1. The extended fixed tongue: proof of theorem C

The goal of this section is to prove theorem C, which describes the shape of the connected components of the extended fixed tongue $\mathcal{ET}_0$ (see figure 9).

We need an auxiliary proposition to prove theorem C. The fixed tongue $T_0$ has three connected components, only one modulo symmetry (see theorem A). Therefore, when studying the extended fixed tongue we restrict to the connected component which intersects the real line. It is convenient to consider the parameter plane given by $(r, \alpha)$, where $a = r e^{2\pi i \alpha}$, $1 < r < 2$ and $\alpha \in [0, 1/3)$. We then use the alternative parametrization $g_{r,\alpha} = B_{r,|\alpha|/2}$ of $B_{a/\alpha}$.
(see section 2.1). We denote by \( h_{r,\alpha} \) the lift of \( g_{r,\alpha} \) (see equation (5)). We want to remark that for \( r = 1 \) and \( x = 0 \) the function is not well defined (see section 2). Indeed, for \( r = 1 \), the two critical points and the preimages of 0 and \( \infty \) collapse at the point \( x = 0 \) and the function becomes a degree 3 polynomial. The following proposition gives us the main properties of \( \mathcal{ET}_b \).

**Proposition 5.3.** Let \( \mathcal{ET}_b \) denote the extended fixed tongue which intersects the real line. Then, \( \mathcal{ET}_b \) satisfies the following properties:

(a) \( \mathcal{ET}_b \) is symmetric with respect to the real line.

(b) For fixed \( r_0 \), \( 1 < r_0 < 2 \), \( \mathcal{ET}_b \cap \{ \alpha \geq 0 \} \cap \{ r = r_0 \} \) is a connected set on which the multiplier is strictly increasing with respect to \( \alpha \) and takes values in \( (b, 1) \), where \(-1 \leq b < 0 \).

Moreover, \( b = -1 \) if and only if \( r_0 \leq 5/3 \).

(c) If \( (r, \alpha) \in \mathcal{ET}_b \) then \(-1/6 < \alpha < 1/6 \).

**Proof.** For statement (a) we notice that the extended tongue is symmetric with respect to the real line due to the symmetry of the parameter plane \( a \rightarrow \bar{a} \) (see lemma 2.3), so we restrict the study to \( \alpha \geq 0 \). We now use the lift \( h_{r,\alpha} \) of \( g_{r,\alpha} \) (see equation (5)) to prove (b) and (c). Recall that it is given by

\[
h_{r,\alpha}(x) = 3x + 3\alpha + \frac{1}{2\pi i} \log \left( \frac{e^{2\pi i x} - r}{1 - re^{2\pi i x}} \right).
\]

The extended fixed tongue \( \mathcal{ET}_b \) consists of the parameters for which \( h_{r,\alpha} \) has an attracting fixed point which can be continued to the superattracting fixed point \( x_{r,0} = 0 \) of \( h_{2,0} \), where the parameter \( (2, 0) \) corresponds to the root \( 2 = 2e^{2\pi i b} \) of the fixed tongue \( T_b \).

The point \( x_{r,0} = 0 \) is a fixed point of \( h_{r,0} \) for all \( r \in (1, 2] \). We use the monotonicity of \( h_{r,\alpha} \) with respect to \( \alpha \) to continue this fixed point for \( \alpha > 0 \). We denote by \( x_{r,\alpha} \) the fixed point of \( h_{r,\alpha} \) obtained by continuation of \( x_{r,0} = 0 \). This point \( x_{r,\alpha} \) is well defined as long as we do not reach a parameter \( \alpha \) for which \( x_{r,\alpha} \) has multiplier 1. Such a parameter would belong to the boundary of the extended tongue, so this is not an obstruction. Notice also that \( x_{r,\alpha} \) is strictly decreasing with respect to \( \alpha \) since \( h_{r,\alpha} \) is strictly increasing with respect to \( \alpha \).

To determine if a parameter \((r, \alpha)\) belongs to the extended fixed tongue, we have to study the multipliers of the fixed points \( x_{r,\alpha} \). Recall from equation (6) that the derivative of \( h_{r,\alpha} \) is given by

\[
h'_{r,\alpha}(x) := \frac{\partial}{\partial x} h_{r,\alpha}(x) = 3 + \frac{1 - r^2}{1 + r^2 - 2r \cos(2\pi x)}.
\]

Notice that it does not depend on \( \alpha \). The multiplier of the fixed point \( x_{r,0} \) is given by \( h'_0(0) = 3 + (1 + r)/(1 - r) \), which decreases from 0 to \(-\infty \) as \( r \) decreases from 2 to 1. Moreover, \( h'_{r}(5/3) = -1 \). The proof of (b) will be finished finding, for every fixed \( r \) with \( 1 < r \leq 2 \), a parameter \( \alpha(r) \) such that \( x_{r,\alpha(r)} \) has multiplier 1 and such that the multipliers of \( x_{r,\alpha} \) increase from \( h'_0(0) \) to 1 as \( \alpha \) increases from 0 to \( \alpha_1(r) \).

Fixed \( r \) with \( 1 < r \leq 2 \), the monotonicity of the multiplier of \( x_{r,\alpha} \) with respect to \( \alpha \) follows from the fact that \( h'_r \) is strictly increasing as \( x \) decreases from 0 to \(-1/2 \). The condition \( 0 < x < -1/2 \) is not an obstruction since \( h'_r(-1/2) = 3 + (1 - r^2)/(1 + r^2 + 2r) > 1 \) for all \( 1 < r \leq 2 \) and, therefore, no parameter \((r, \alpha)\) with \( x_{r,\alpha} = -1/2 \) can belong to the extended fixed tongue or its boundary.
We now prove that for all \( r \in (1, 2] \), there exists an \( \alpha_0(r) = \alpha_1 \) which depends continuously on \( r \) such that \( h'_r(x_{r, \alpha_0}) = 1 \) and \( 0 < \alpha_1 < 1/6 \). First of all we notice that, given a parameter \((r, \alpha(r))\) with a fixed point \( x_{r, \alpha(r)} = x_1 \) of multiplier 1, the map \( h_{r, \alpha(r)} \) can be written as

\[
h_{r, \alpha(r)}(x) = x + \eta(x - x_1)^2 + \mathcal{O}((x - x_1)^3)
\]

in a neighborhood of \( x_1 \), where \( \eta \in \mathbb{R} \). We conclude that \( \alpha_1(r) \) is a local graph with respect to \( r \) unless \( \eta = 0 \). However, \( \eta \) is zero if \( \partial^2 h_{r, \alpha(r)}/\partial x^2(x_1) = 0 \), which can only happen if \( x_1 = 0 \) or \( x_1 = -1/2 \). Since \( h'_r(-1/2) = 3 + (1 - r^2)(1 + r^2 + 2r) > 1, x = -1/2 \) cannot be a parabolic fixed point. Moreover, the point \( x = 0 \) cannot be a parabolic fixed point with multiplier 1 since \( h'_r(0) \leq 0 \) if \( 1 < r \leq 2 \).

Next we prove that \( \alpha_1(r) < 1/6 \) by contradiction. Assume that there is an \( r \) for which this is not the case. Then, by continuity, there would be an \( \tilde{r} \) so that \( h'_{r}(x_{r, 1/6}) = 1 \). Because of the symmetries in the parameter plane, this parameter would give us the intersection between the boundaries of the extension of two different connected components of the fixed tongue. Therefore, at this parameter we would have two different fixed points of multiplier 1. However, each of these parabolic points is a fixed point of multiplicity two and, therefore, this situation would require at least 4 fixed points. This would contradict the fact that the Blaschke products \( B_r \) can have at most 3 fixed points other than \( z = 0 \) and \( z = \infty \).

Summarizing we have proven that, for all \( r \in (1, 2) \), the fixed point \( x_{r, 0} = 0 \) of \( h_{r, 0} \) can be monotonously continued to a fixed point \( x_{r, \alpha} \) of \( h_{r, \alpha} \) as long as \( \alpha < \alpha_1(r) < 1/6 \), where \( \alpha_1(r) \) is a continuous function with respect to \( r \). Moreover, for \( 0 \leq \alpha < \alpha_1(r) \) the multiplier of \( x_{r, \alpha} \) is strictly increasing and takes values in \( [h'_r(0), 1) \), where \( h'_r(0) \leq -1 \) if and only if \( r \leq 5/3 \). This finishes the proof of the proposition.

Using the previous proposition we can prove theorem C.

**Proof of theorem C.** The fact that two extensions of connected components of the extended fixed tongue cannot intersect follows from statement (c) of proposition 5.3 using the symmetries of the parameter plane and that all connected components of the fixed tongue are symmetric with respect to the rotations given by the third roots of the unity (see theorem A).

The boundary of the connected components of ET_0 is the union of an exterior boundary with parameters of multiplier 1 and an interior boundary with parameters of multiplier \( -1 \) by statement (b) of proposition 5.3.

We finally prove that there is a period doubling bifurcation taking place throughout the interior curve. Let \( (r, \alpha_{-1}) \), \( r < 5/3 \), be a parameter of the interior curve. Then \( h_{r, \alpha_{-1}} \) has a parabolic fixed point of multiplier \( -1 \), say \( x_- \). Hence, \( x_- \) is a parabolic fixed point of multiplier 1 of \( h^2_{r, \alpha_{-1}} \). Using that \( h_{r, \alpha_{-1}}(x_-) = x_- \) and \( h'_{r, \alpha_{-1}}(x_-) = -1 \) it is not difficult to prove that \( \partial^2 h^2_{r, \alpha_{-1}}/\partial x^2(x_-) = 0 \) and, therefore, \( x_- \) is a parabolic fixed point of multiplicity 3 of \( h^2_{r, \alpha_{-1}} \).

Hence, \( x_- \) has two attracting petals which intersect the unit circle since all critical points lie in \( S^1 \). Consequently, \( x_- \) is topologically attracting on the unit circle. Using that \( h^2_{r, \alpha_{-1}} \) is monotonously decreasing with respect to \( \alpha \) in an open neighborhood of \( x_- \) and performing the same perturbations as in lemma 3.19 we conclude that, if \( \alpha \in (\alpha_{-1} - \epsilon, \alpha_{-1}) \cup (\alpha_{-1}, \alpha_{-1} + \epsilon) \) with \( \epsilon > 0 \) small enough, then \( h^2_{r, \alpha} \) has a topologically attracting fixed point. It follows from the monotonicity of the multipliers of the fixed points of \( h_{r, \alpha} \) with respect to \( \alpha \) shown in proposition 5.3 that either the parameters \( (r, \alpha) \) with \( \alpha < \alpha_{-1} \) or the \( (r, \alpha) \) with \( \alpha > \alpha_{-1} \) are such that \( h_{r, \alpha} \) has a period two attracting cycle.
5.2. Numerical conjectures

We finish this section giving some ideas about the dynamics that take place on \( A_{1,2} \) other than the ones given by the extended fixed tongue. Numerical studies suggest that the properties described for the extended fixed tongue \( ET_0 \) are common to all extended tongues. Indeed, we conjecture that all extended tongues have a similar structure than the one presented in proposition 5.3.

**Conjecture 5.4.** Given an extended tongue \( ET_\ell \) of period \( p > 1 \), its connected components are disjoint. The boundary of every connected component of the extended tongue \( ET_\ell \) consists of two disjoint connected components. The exterior component consists of parameters for which there is a parabolic cycle of period \( p \) and multiplier 1. The interior component consists of parameters for which there is a parabolic cycle of period \( p \) and multiplier \(-1\). Moreover, there is a period doubling bifurcation taking place throughout the curve of interior boundary parameters.

We also focus on how extended tongues, and more generally hyperbolic components, accumulate on the unit circle. In figure 9 we see that the boundaries of the extended fixed tongue accumulate tangentially to the unit circle onto isolate points. Moreover they do it in pairs. By this we mean that given an accumulation point \( l, |l| = 1 \), the boundaries of two different connected components of the extended fixed tongue land on it. This seems to happen for hyperbolic regions of arbitrary period. In figure 8 (right) we can observe how the boundary of an extended tongue of period 2 (drawn in green) accumulates onto a parameter \( l, |l| = 1 \), together with another hyperbolic region of period 2 not coming from the extension of a tongue.

**Conjecture 5.5.** Parabolic curves accumulate on the unit circle on isolate points and tangentially to it. Moreover, if a parabolic curve accumulates on a parameter \( l, |l| = 1 \), then there is another parabolic curve of the same period landing on \( l \) from the opposite side.
We also want to point out that the observed bifurcation structures are similar to the ones described for more general maps of $\mathbb{R}^2$ (see [BST98, CMB +91, GSV13]). Indeed, the observed structure around extended tongues is very similar to the one of spring-areas associated to homoclinic tangencies. In that later case, it is proven that there are cascades of period doubling bifurcations which are also observed for the family $B_c$. In figure 8 we can see these period doublings to period 2 and 4. Other structures of bifurcations described in these papers such as Cross-roads also seem to appear for the Blaschke family $B_a$ when $1 < |a| < 2$ (see figure 10).

Acknowledgments

The authors would like to thank A Dezotti, A Epstein, M Misiurewicz, J C Naranjo, M Sáez, A Vieiro, and the referees for their many and useful comments which greatly improved this paper.
