Abstract
Following the official announcement of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) worldwide pandemic spread by WHO on March 11, 2020, more than 300,000 COVID-19 cases reported in Iran resulting in approximately 17,000 deaths as of August 2, 2020. In the present survey, we investigated the presence of SARS-CoV-2 RNA in raw and treated wastewater samples in Tehran, Iran. Untreated and treated wastewater samples were gathered from four wastewater treatment plants over a month period from June to July 2020. Firstly, an adsorption-elution concentration method was tested using an avian coronavirus (infectious bronchitis virus, IBV). Then, the method was effectively employed to survey the presence of SARS-CoV-2 genome in influent and effluent wastewater samples. SARS-CoV-2 RNA was found in 8 out of 10 treated wastewater samples utilizing a reverse transcription-quantitative polymerase chain reaction (RT-qPCR) test to detect ORF1ab and N genes. Moreover, the rate of positivity in wastewater samples increased in last sample collection that shows circulation of SARS-CoV-2 was increased among the population. In addition, the high values detected in effluent wastewater from local wastewater treatment plants have several implications in health and ecology that should be further assessed.

Keywords SARS-CoV-2 · COVID-19 · Wastewater · Influent water · Effluent · Iran

Introduction
Coronavirus disease 2019 (COVID-19) is the ongoing global pandemic, caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and was first described in Wuhan, China, in December 2019 (WHO 2020b). From the first detected case, in less than 6 months, SARS-CoV-2 has caused approximately 14 million infections and more than half a million deaths. Initial COVID-19 in Iran was reported on February 19, 2020, followed by the first reported case in Tehran on February 19, 2020 (WHO 2020a).

The name “coronavirus” is derived from a Latin word “corona,” meaning “crown” or “wreath,” due to the morphology of the virus, the name has been given. This morphology is formed by the viral spike peplomers that are proteins on the virus envelope. These surface proteins are involved in several...
features of the virus life cycle, such as assembly, envelope formation, and pathogenesis. Inside the envelope is the helical capsid holding nucleoprotein and the RNA genome. The coronavirus genome is encoded in a positively polarized RNA strand of approximately 30,000, making it the largest known RNA virus with a non-fragmented genome (Mlejnкова et al. 2020).

Coronavirus infection can lead to mammals and avian diseases. In humans, they are commonly responsible for mild to severe respiratory involvement and even death in some cases. Some of the coronaviruses can cause mild disease like common cold, on the other hand, other coronaviruses including SARS, MERS, and COVID-19 may create lethal diseases. The symptoms of COVID-19 patients include cough, fever, and difficulty in breathing; moreover, 2–10% of them had gastrointestinal symptoms, comprehend diarrhea (Cai et al. 2020; Gao et al. 2020; Holshue et al. 2020; Liu et al. 2020; Tang et al. 2020; Wölfel et al. 2020; Zhang et al. 2020a, b). Side effects of COVID-19 disease include changing or even losing of smell and taste senses, nausea, sore throat, body aches, and headache (NCIRD 2021).

The main transmission route of SARS-CoV-2 is through respiratory secretion droplet generation during breathing, sneezing, coughing, and also direct/indirect contact. Though, the genomic RNAs of these viruses have been found in patients stool and also urine specimens. Recent publications revealed that SARS-CoV-2 RNA has also been detected in feces and anal/rectal swabs (Cai et al. 2020; Gao et al. 2020; Holshue et al. 2020; Tang et al. 2020; Wölfel et al. 2020; Xiao et al. 2020; Zhang et al. 2020a, b). Wang and colleagues found that SARS-CoV-2 RNA could be isolated from stool samples in around 29% of patients (Wang et al. 2020a, b, d; Xiao et al. 2020). Also SARS-CoV-2 RNA has been more seen in fecal samples from hospitalized patients. Even after resolution of respiratory symptoms, persistence shedding of viral RNA in stool samples continues in some cases (Xiao et al. 2020). In addition, the scale of the virus shedding may vary widely from $10^2$ up to $10^8$ RNA copies per gram (Lescure et al. 2020; Pan et al. 2020; Wölfel et al. 2020). These studies recommended that viral fecal shedding could persist for several days in individuals without gastrointestinal symptoms. Therefore, asymptomatic individuals with negative nasopharyngeal test result may disperse SARS-CoV-2 into the environment (Jiang et al. 2020). Also a recent study suggests that SARS-CoV-2 remains in the stool (medium, 22 days) longer than the respiratory form (18 days) (Zheng et al. 2020).

As public urban wastewater network collects significant amounts of symptomatic and asymptomatic patients’ feces, SARS-CoV-2 might be found for approximately a long period of time in public wastewater pipe network, becoming a secondary spreading source. In addition, treated sewage from hospitals also adds a notable risk of SARS-CoV-2 accumulation into sewage collection systems. Consequently, in addition to direct contact and respiratory droplets, fecal-oral spread route can be another important transmission route to increasing the virus circulation in different populations.

Recently, the presence of SARS-CoV-2 RNA has been reported in wastewater treatment plants in Australia, Italy, Spain, the Netherlands, USA, Japan, Germany, UAE, Istanbul, and Brazil (Ahmed et al. 2020a, 2020b, 2020c; La Rosa et al. 2020a, b; Medema et al. 2020; Randazzo et al. 2020a, 2020b; Shcheran et al. 2020; Prado et al. 2021, Kocamemi et al. 2020, Westhaus et al. 2021, Albastaki et al. 2020) and some studies have also examined the presence of this virus in river water (Rimoldi et al. 2020a; Haramoto et al. 2020; Guerrero-Latorre et al. 2020).

Method for concentration and detection of SARS-CoV-2 was one of the main technical challenges in WBE studies (Ahmed et al. 2020b). Due to the difference between recovery and detection in enveloped and non-enveloped viruses, SARS-CoV-2 as an enveloped virus, we have a lack of information about its recovery in wastewater. Recent studies have used several virus concentration methods to recover and accumulate SARS-CoV-2 from wastewater. According to recent studies, different recovery methods such as centrifugal ultrafiltration device (Medema et al. 2020; Ahmed et al. 2020a), the adsorption-extraction technique utilizing electronegative membrane (La Rosa et al. 2020a, b), a two-phase PEG-dextran method, and aluminum hydroxide adsorption-precipitation technique (Randazzo et al. 2020b) have been recently applied.

Based on this background and our previous study on Torque teno virus (TTV) in a wastewater treatment plant in Tehran (Tavakoli Nick et al. 2019), in the present study, we investigated the presence of SARS-CoV-2 RNA and demonstrated the first report of the presence of it in untreated and treated wastewater samples in Iran collected from four different wastewater treatment plants (WWTPs) in Tehran.

**Materials and methods**

**Collection of water samples**

Eleven samples were collected between the 30th of June and the 31st of July 2020, from four WWTPs, located in Tehran (four distinct plants, reported as A, B, C, and D, respectively). A total of eleven samples were collected, including one sample from the input of one of the WWTPs and ten samples from the final effluent of each WWTP. Samples were collected in sterilized 4-L plastic bottles taking precautionary measures and transported to the Virology Laboratory in Research Institute for Gastroenterology and Liver Diseases, Shahid Beheshti University of Medical Sciences, Tehran, Iran, on ice and processed within 6 h of collection.
**Virus concentration**

Viruses in samples were concentrated by an adsorption-elution method using an electronegative filter (Katayama et al. 2002). Briefly, 2.5 M MgCl₂ was included to the sample to reach a final concentration of 25 mM. Then, 1-L effluents and 200-mL influent were filtered using a six-branch filtration system (Sartorius, Goettingen, Germany) and sterile 47-mm cellulose nitrate membrane (Sartorius, Goettingen, Germany) with pore size 0.45 μm. Afterwards, the filter was rinsed with 200 mL of 0.5 mM H₂SO₄ (pH 3.0) followed by elution of the viruses from the membrane filter using 10 mL of 1.0 mM NaOH (pH 10.8). The filtrate was recovered as a primary concentrate in a vessel containing 50 μL of 100 mM H₂SO₄ and 100 μL of 100× Tris–EDTA buffer. Eluates containing viruses were further concentrated by polyethylene glycol (PEG-6000, Merck, Darmstadt, Germany) precipitation method as described previously (Vilagines et al. 1997) with some modifications. In brief, 12.5% PEG-6000 and 2.5% NaCl at final concentration were included, the eluate was mixed at 4 °C for 2 h and centrifuged at 10,000 ×g for 30 min. The pellet was suspended in 200 μL of PBS (pH 7.2) and the suspension was stored at −20 °C until used (Fig. 1).

**Viral RNA extraction**

Viral nucleic acids were extracted from 140 μL of the final elute obtained from the second concentration step using a QIAamp RNA mini kit (Qiagen, Germany) according to the manufacturer’s protocol. The extracted nucleic acid was kept at −20 °C until additional downstream analysis.

**RT-qPCR analysis**

The occurrence of SARS-CoV-2 RNA in wastewater was detected by real-time reverse transcription polymerase chain reaction (RT-qPCR) using the kits of Sansure Biotech Inc. (Changsha, China) and Shanghai Zhijiang Biotechnology Co. (Shanghai, China), according to the manufacturer’s instructions and quantitative analysis of gene N individually conducted with probes and primers. In quantitative analysis, the standard curve was plotted according to different dilutions of in vitro transcription RNA (N gene). Specificity of the assay targeting two parts of the SARS-CoV-2 genome is declared by the manufacturer. Samples with a cycle quantification value (Cq) < 40 were considered positive. For positive and negative controls of PCR, the positive control kit, containing in vitro transcriptional RNA target genes (ORF1ab, N gene) and its internal standard gene fragments (Rnase P), and negative control, namely normal saline, were used. Amplification and fluorescence detection were performed on a Rotor-Gene® Q (Qiagen, Germany).

**Result**

Among the eleven wastewater samples which were tested, the amplification of SARS-CoV-2 RNA genes ORF1ab and N was successful in the influent of one of the WWTPs on June 30th, 2020. Moreover, ten samples were gathered from WWTP A, WWTP B, WWTP C, and WWTP D outlets on three separate sampling events (10/07/2020, 21/07/2020, and 31/07/2020) which all were positive for SARS-CoV-2 except of WWTP A that means the 80% (8 positive samples out of 10) of effluent samples were tested positive for both SARS-CoV-2 RT-qPCR targets (Table 1). Samples were considered positive for Ct below 40. Ct values ranged from 29.62 to 34.45 (ORF1ab) and 27.60 to 30.53 (N), respectively. Positive samples that were quantitatively evaluated for the N gene were RNA copies found in them ranging from 7.18E + 01 to 1.09E + 03 GC/mL (Fig. 2). The modified electronegative method was tested by spiking effluent with IBV. On average, IBV was recovered at ranges of 11.78 ± 1.76.

**Discussion**

Characteristically, concentrating enteric viruses from wastewater and environmental waters was done by adsorption-elution method based on electronegative membrane. Thus, electronegative membrane is one of the
suitable candidates for concentrating enveloped viruses. Previous studies confirmed that utilizing the electronegative membrane provides a superior adsorption of enveloped viruses such as \textit{Pseudomonas} phage \textit{Φ6} and mouse hepatitis virus to the solid fraction of wastewater compared to non-enveloped viruses (Ye et al. 2016). Other than electronegative membranes, the polyethylene glycol (PEG) has been extensively applied to re-concentrating SARS-CoV-2 in wastewater samples. On the other hand, just one study to date has reported the percent recovery of SARS-CoV from wastewater which was estimated to be only 1\% using an electropositive membrane (Wang et al. 2005). Meanwhile, the differences between SARS-CoV-2 and enteric viruses showed that more research is necessary for the effective recovery of SARS-CoV-2 from wastewater.

In the current investigation, we used an enveloped virus, namely, avian coronavirus (IBV), for the detection of SARS-CoV-2 in wastewaters. Avian coronavirus (IBV) is a member of Coronaviridae family that infects birds, causing the associated disease avian infectious bronchitis (IB). It is a highly contagious avian pathogen which influences on the respiratory tract, kidney, gut, and reproductive systems of chickens (Casais et al. 2001; Cavanagh 2001). IBV belongs to the genus Gammacoronavirus (Bande et al. 2016), or group 3 (Cavanagh 2007), with a single-stranded RNA genome. The mean recovery efficiency was acceptable, representative that there was no considerable inhibition or loss occurred during the RNA extraction and RT-qPCR (Acevedo et al. 2013), moreover electronegative membrane was satisfactory as a concentration method for an enveloped virus.

Recently, SARS-CoV-2 RNA in influent water has been detected and described worldwide (Ahmed et al. 2020a; La Rosa et al. 2020a, b; Lodder and de Roda Husman 2020; Medema et al. 2020; Nemudryi et al. 2020; Randazzo et al. 2020). Table 1 illustrates the presence of SARS-CoV-2 in raw and treated wastewater samples collected from different WWTPs in June, July, and August 2020. The table shows that the Ct values of real-time PCR amplification of SARS-CoV-2, as obtained for WWTPs. Genes code refers to the N gene and Orf1ab gene.

### Table 1

| Sample origin | Station | Treatment | Date       | Gene positivity |
|---------------|---------|-----------|------------|-----------------|
| WWTPs         | A       | Raw       | June 30th  | 29.62 29.96     |
|               | A       | Treated   | –          | –  –            |
|               | B       | Treated   | July 10th  | 33.76 30.53     |
|               | C       |           |            | 31.66 28.39     |
|               | D       |           |            | 33.33 30.42     |
|               | B       | Treated   | July 21st  | 33.96 30.10     |
|               | C       |           |            | 34.45 30.39     |
|               | A       | Treated   | July 31st  | –  –            |
|               | B       |           |            | 30.78 27.85     |
|               | C       |           |            | 33.65 30.13     |
|               | D       |           |            | 30.61 27.60     |

**Fig. 2** SARS-CoV-2 specific RNA fragment detected by N gene RT-qPCR in the effluents. Results of a single PCR measurement are shown for N gene. For N gene RT-qPCR, CT values for the standard ranged between 21.8 (standard 1 = 10\(^6\)) and 32.6 (standard 4 = 10\(^3\)). Values of tested wastewater above CT 40 were considered negative for SARS-CoV-2.
As similar studies conducted in Paris demonstrated the detection of viral genome in effluent (Wurtzer et al. 2020). According to Wurtzer et al. (2020), all raw wastewater samples and 6 out of 8 treated wastewater samples were positive for SARS-CoV-2. Recently, a similar study was published in Germany, in which the presence of the virus in raw and treated wastewater was quantitatively investigated. The results of this study indicate the presence of the virus in all influent and effluent samples of treatment plants. Therefore, in this study our focus was on effluent and just grabbed one raw wastewater to confirmed presence of the SARS-CoV-2. Of the eleven wastewater samples tested, SARS-CoV-2 RNA was not detected only in 20% (2/10) of effluent wastewater samples by Sansure COVID-19 RT-qPCR, which had been collected from WWTP A (Fig. 3).

The concentration of SARS-CoV-2 in the effluent in this study (10^1 to 10^3 GC/mL) is almost similar to other studies such as the one conducted in Germany (Westhaus et al. 2020).
Of course, the wider range of the presence of the virus in the sewage indicates changes in the number of patients in different time periods.

These results show that wastewater treatment in main WWTPs, such as WWTP A, is performed correctly, unlike local wastewater treatment plants. Meanwhile, the local wastewater treatment plant discharges its treated effluent into urban rivers and canals. Consequences of this occurrence included; first, there is a risk of infection for the population in contact with downstream water due to the presence of SARS-CoV-2, like other microbial pathogens, which is discharged into open river water. In addition, the persistence of SARS-CoV-2 RNA in water can cause the recirculation of COVID-19 in our communities. However, it is noteworthy that only genomic material has been identified in the wastewater, the detection of viable and the titer of the intact virus are essential in contaminated wastewater need to be determined, and also its ability to transmit through fecal-oral route has not yet been established. Second, the transmission of the virus in the environment has an unknown effect on the food safety such as vegetables and other foods that are eaten raw, through them can cause further spread of the disease.

Nowadays, in the second peak of COVID-19 pandemic in Iran, comparison of the average level of SARS-CoV-2 genomes in the last wastewater samples with the earlier wastewater samples confirmed that the increase of viral genome in effluent perfectly monitored the increase in the number of new cases confirmed in the country on the onset of the second peak of COVID-19 (Fig. 4).

Conclusion

In this study, raw and treated wastewater samples were collected from 4 treatments plants in Tehran and concentrated by membrane filtration and PEG perception. Meanwhile, raw wastewater along with 8 treated wastewater samples were infected with SARS-CoV-2 virus. Given these results, as well as the discharge of effluents from these treatment plants into rivers and urban canals, it warns governments to have more oversight and control over the performance of urban and local treatment plants.

Acknowledgements The present study was funded by the Research Institute for Gastroenterology and Liver Diseases, Shahid Beheshti University of Medical Sciences, Tehran, Iran. The authors would like to appreciate the RIGLD laboratory staff especially Mrs. Mahsa Saeedi Niasar.

Author contribution SMH, MRZ, and SRM conceived the study; MT, MR, and SHSH performed the sample and data collection; MT, MR, SHK, and SRM carried out the laboratory and molecular tests; MT, HM, AG, and SRM carried out the interpretation and analyze of the data; MT, MR, and SMH drafted the manuscript; and SRM, AG, HAA, and MRZ critically revised the manuscript for intellectual content. All authors read and approved the final manuscript.

Data availability The datasets generated and/or analyzed during the current study by the authors is at the disposal of the corresponding author, which will be published upon reasonable request.
