PERIOD PROBLEMS
FOR MEAN CURVATURE ONE SURFACES IN $H^3$
(WITH APPLICATION TO SURFACES OF LOW TOTAL CURVATURE)

WAYNE ROSSMAN, MASAAKI UMEHARA, AND KOTARO YAMADA

Abstract. We survey our recent results on classifying complete constant mean curvature 1 (CMC-1) surfaces in hyperbolic 3-space with low total curvature. There are two natural notions of “total curvature”—one is the total absolute curvature which is the integral over the surface of the absolute value of the Gaussian curvature, and the other is the dual total absolute curvature which is the total absolute curvature of the dual CMC-1 surface. Here we discuss results on both notions (proven in two other papers by the authors), and we introduce some new results (with proofs) as well.

1. Introduction

There is a wide body of knowledge about minimal surfaces in Euclidean 3-space $R^3$, and there is a canonical local isometric correspondence (sometimes called the Lawson correspondence) between minimal surfaces in $R^3$ and CMC-1 (constant mean curvature one) surfaces in hyperbolic 3-space $H^3$ (the complete simply-connected 3-manifold of constant sectional curvature $-1$). This has naturally led to the recent interest in and development of CMC-1 surfaces in $H^3$ in the last decade. There are now many known examples, and it is a natural next step to classify all such surfaces with low total absolute curvature.

By this canonical local isometric correspondence, minimal immersions in $R^3$ are locally equivalent to CMC-1 immersions in $H^3$. But there are interesting differences between these two types of immersions on the global level. There are period problems on non-simply-connected domains of the immersions, which might be solved for one type of immersion but not the other. Solvability of the period problems
is usually more likely in the $H^3$ case, leading to a wider variety of surfaces there. For example, a genus 1 surface with finite total curvature and two embedded ends cannot exist as a minimal surface in $R^3$, but it does exist as a CMC-1 surface in $H^3$. And a genus 0 surface with finite total curvature and two embedded ends exists as a minimal surface in $R^3$ only if it is a surface of revolution, but it may exist as a CMC-1 surface in $H^3$ without being a surface of revolution (see Example 4.3). So there are many more possibilities for CMC-1 surfaces in $H^3$ than there are for minimal surfaces in $R^3$. This means that it is more difficult to classify CMC-1 surfaces with low total curvature in $H^3$.

To find complete CMC-1 surfaces in $H^3$ with low total curvature, we must first determine the meromorphic data in the Bryant representation of the surfaces that can admit low total curvature, and then we must analyse when the parameters in the data can be adjusted to close the period problems. Generally, finding the data is the easier step, and solving the period problems is the more difficult step. As the period problems are generally the crux of the problem, we have chosen the title of this paper to reflect this.

The total absolute curvature of a minimal surface in $R^3$ is equal to the area of the image (counted with multiplicity) of the Gauss map of the surface, and complete minimal surfaces in $R^3$ with total curvature at most $8\pi$ have been classified (see Lopez [Lop] and also Table 2). Furthermore, as the Gauss map of a complete conformally parametrized minimal surface is meromorphic, and has a well-defined limit at each end when the surface has finite total curvature, the area of the Gauss image must be an integer multiple of $4\pi$.

However, unlike minimal surfaces in $R^3$, when searching for CMC-1 surfaces in $H^3$ with low total curvature, we have a choice of two different Gauss maps: the hyperbolic Gauss map $G$ and the secondary Gauss map $g$. So there are two ways to pose the question in $H^3$, with two very different answers. One way is to consider the true total absolute curvature, which is the area of the image of $g$, but since $g$ might not be single-valued on the surface, the total curvature might not be an integer multiple of $4\pi$, and this allows for many more possibilities. Furthermore, the Osserman inequality does not hold for the true total absolute curvature. The weaker Cohn-Vossen inequality is the best general lower bound for true absolute total curvature (with equality never holding [UY5, Yu2]). So the true total absolute curvature is difficult to analyse, but it is important because of its clear geometric meaning.

The second way is to study the area of the image of $G$, which we call the dual total absolute curvature, as it is the true total curvature of the dual CMC-1 surface (which we define in Section 3) in $H^3$. This way has the advantage that $G$ is single-valued on the surface, and so the dual total absolute curvature is always an integer multiple of $4\pi$, like the case of minimal surfaces in $R^3$. Furthermore, the dual total curvature satisfies not only the Cohn-Vossen inequality, but also the Osserman inequality [UY3, Yu2] (see also (3.13) in Section 3). So the dual total curvature shares more properties with the total curvature of minimal surfaces in $R^3$, motivating our interest in it.

We shall refer to the true total absolute curvature of a CMC-1 immersion $f: M \to H^3$ of a Riemann surface as $TA(f)$, and the dual total absolute curvature as $TA(f^\#)$.

We review the classification results for surfaces with $TA(f) \leq 4\pi$ or $TA(f^\#) \leq 4\pi$ in Section 2, which are results from RUY4 and RUY5. An inequality for
TA(f) stronger than the Cohn-Vossen inequality \[ RUY4 \] is also introduced. In Section 3, we review basic notions and terminology. We introduce some important examples of CMC-1 surfaces in Section 4. Section 5 is devoted to describing the results in \[ RUY3 \], a partial classification of CMC-1 surfaces with \( \text{TA}(f) \leq 8\pi \). Using the preliminaries in Section 6, a partial classification of CMC-1 surfaces with \( \text{TA}(f) \leq 8\pi \) is discussed, with proofs, in Section 7.

2. The cases TA(f) or TA(f\#) ≤ 4π, and a natural extension

In \[ RUY4 \] the following theorem was proven:

**Theorem 2.1.** Let \( f : M \to H^3 \) be a complete CMC-1 immersion of total absolute curvature \( \text{TA}(f) \leq 4\pi \). Then \( f \) is either

- a horosphere (Example 4.1),
- an Enneper cousin (Example 4.2),
- an embedded catenoid cousin \((0 < l < 1, \delta = 1 \text{ and } b = 0 \text{ in Example 4.3})\),
- a finite \( \delta \)-fold covering of an embedded catenoid cousin \((\delta \geq 2, 0 < l \leq 1/\delta \text{ and } b = 0 \text{ in Example 4.3})\), or
- a warped catenoid cousin with injective secondary Gauss map \((l = 1, \delta \in \mathbb{Z}^+ \text{ and } b > 0 \text{ in Example 4.3})\).

The horosphere is the only flat (and consequently totally umbilic) CMC-1 surface in \( H^3 \). The catenoid cousins are the only CMC-1 surfaces of revolution \[ Bry \]. The Enneper cousins are isometric to minimal Enneper surfaces \[ Bry \]. The warped catenoid cousins \[ Y1, RUY3 \] are less well known and are described more precisely in Section 4, as well as the other above three examples.

Although this theorem is simply stated, for the reasons given in the introduction the proof is more delicate than it would be if the condition \( \text{TA}(f) \leq 4\pi \) is replaced with \( \text{TA}(f\#) \leq 4\pi \), or if minimal surfaces in \( R^3 \) with \( \text{TA} \leq 4\pi \) are considered. CMC-1 surfaces \( f \) with \( \text{TA}(f\#) \leq 4\pi \) are classified in Theorem 2.3 below. It is well-known that the only complete minimal surfaces in \( R^3 \) with \( \text{TA} \leq 4\pi \) are the plane, the Enneper surface, and the catenoid (see Table 2).

We extend the above result in Section 4 to find an inclusive list of possibilities for CMC-1 surfaces with \( \text{TA}(f) \leq 8\pi \), and we consider which possibilities we can classify or find examples for, see Table 3. (Minimal surfaces in \( R^3 \) with \( \text{TA} \leq 8\pi \) are classified by Lopez \[ Lop \]. See Table 3.)

For a complete CMC-1 immersion \( f \) in \( H^3 \), equality in the Cohn-Vossen inequality never holds (\[ Y1, Theorem 4.3 \]). In particular, if \( f \) is of genus 0 with \( n \) ends, then

\[
\text{TA}(f) > 2\pi(n - 2) .
\]

When \( n = 2 \), the catenoid cousins show that (2.1) is sharp. However, we see from the above theorem that

\[
\text{TA}(f) > 4\pi \text{ for } n = 3 ,
\]

which is stronger than the Cohn-Vossen inequality (2.1). The following theorem, which extends the above theorem and is proven in \[ RUY4 \], gives a sharper inequality than the Cohn-Vossen inequality when \( n \) is any odd integer:
Theorem 2.2. Let \( f : C \cup \{ \infty \} \setminus \{ p_1, \ldots, p_{2m+1} \} \to H^3 \) be a complete conformal genus 0 CMC-1 immersion with \( 2m + 1 \) ends, \( m \in \mathbb{Z}^+ \). Then
\[
\text{TA}(f) \geq 4\pi m.
\]

Remark. When \( m = 1 \), we know that the lower bound \( 4\pi \) in the theorem is sharp (see Example 4.4). However, we do not know if it is sharp for general \( m \). For genus 0 CMC-1 surfaces with an even number \( n \geq 4 \) of ends, it is still an open question whether there exists any stronger lower bounds than that of the Cohn-Vossen inequality. It should be remarked that in Section 4 we have numerical examples with \( n = 4 \) whose total absolute curvature tends to \( 4\pi \).

For the case of \( \text{TA}(f^\#) \), the following theorem was proven in [RUY3]:

Theorem 2.3. A complete CMC-1 immersion \( f \) with \( \text{TA}(f^\#) \leq 4\pi \) is congruent to one of the following:

(1) a horosphere (Example 4.1),
(2) an Enneper cousin dual (Example 4.2),
(3) a catenoid cousin (\( \delta = 1, l \neq 1 \) and \( b = 0 \) in Example 4.3), or
(4) a warped catenoid cousin with embedded ends and injective hyperbolic Gauss map (\( \delta = 1, l \in \mathbb{Z}, l \geq 2 \) and \( b > 0 \) in Example 4.3).

3. Basic preliminaries

Before we can state any results for the cases of higher \( \text{TA}(f) \) and higher \( \text{TA}(f^\#) \), we must give some preliminaries here.

Let \( f : M \to H^3 \) be a conformal CMC-1 immersion of a Riemann surface \( M \) into \( H^3 \). Let \( ds^2, dA \) and \( K \) denote the induced metric, induced area element and Gaussian curvature, respectively. Then \( K \leq 0 \) and \( d\sigma^2 := (-K) ds^2 \) is a conformal pseudometric of constant curvature \( 1 \) on \( M \). We call this pseudometric’s developing map \( g : \tilde{M} := \text{the universal cover of } M \to \mathbb{C}P^1 = C \cup \{ \infty \} \) the secondary Gauss map of \( f \). Namely, \( g \) is a conformal map so that its pull-back of the Fubini-Study metric of \( \mathbb{C}P^1 \) equals \( d\sigma^2 \):
\[
\text{(3.1)} \quad d\sigma^2 = (-K) ds^2 = \frac{4 \, dg \, d\bar{g}}{(1 + g \bar{g})^2}.
\]

Such a map \( g \) is determined by \( d\sigma^2 \) uniquely up to the change
\[
\text{(3.2)} \quad g \mapsto \alpha \ast g := \frac{a_{11}g + a_{12}}{a_{21}g + a_{22}}, \quad \alpha = \left( \begin{array}{cc} a_{11} & a_{12} \\ a_{21} & a_{22} \end{array} \right) \in \text{SU}(2).
\]

Since \( d\sigma^2 \) is invariant under the deck transformation group \( \pi_1(M) \), there is a representation
\[
\text{(3.3)} \quad \rho_\sigma : \pi_1(M) \to \text{SU}(2) \quad \text{such that} \quad g \circ \tau^{-1} = \rho_\sigma(\tau) \ast g \quad (\tau \in \pi_1(M)),
\]
where \( \text{SU}(2) = \text{SU}(2)/\{ \pm \text{id} \} \). The metric \( d\sigma^2 \) is called reducible if the image of \( \rho_\sigma \) can be diagonalized simultaneously, and is called irreducible otherwise. In the case \( d\sigma^2 \) is reducible, we call it is \( H^3 \)-reducible if the image of \( \rho_\sigma \) is the identity, and is called \( H^1 \)-reducible otherwise. We call a CMC-1 immersion \( f : M \to H^3 \) \( H^1 \)-reducible (resp. \( H^3 \)-reducible) if the corresponding pseudometric \( d\sigma^2 \) is \( H^1 \)-reducible (resp. \( H^3 \)-reducible). For details on reducibility, see Appendix A.

In addition to \( g \), two other holomorphic invariants \( G \) and \( Q \) are closely related to geometric properties of CMC-1 surfaces. The hyperbolic Gauss map \( G : M \to \mathbb{C}P^1 \)
is holomorphic and is defined geometrically by identifying the ideal boundary of \( H^3 \) with \( \mathbb{CP}^1 \): \( G(p) \) is the asymptotic class of the normal geodesic of \( f(M) \) starting at \( f(p) \) and oriented in the mean curvature vector’s direction. The \textit{Hopf differential} \( Q \) is a holomorphic symmetric 2-differential on \( M \) such that \( -Q \) is the \((2, 0)\)-part of the complexified second fundamental form. The Gauss equation implies

\[
d s^2 \cdot d \sigma^2 = 4 Q \cdot \overline{Q},
\]

where \( \cdot \) means the symmetric product. Moreover, these invariants are related by

\[
S(g) - S(G) = 2Q,
\]

where \( S(\cdot) \) denotes the Schwarzian derivative:

\[
S(h) := \left[ \left( \frac{h''}{h'} \right)' - \frac{1}{2} \left( \frac{h''}{h'} \right)^2 \right] \left( \frac{d}{dz} \right),
\]

with respect to a local complex coordinate \( z \) on \( M \).

In terms of \( g \) and \( Q \), the induced metric \( ds^2 \) and complexification of the second fundamental form \( h \) are

\[
 ds^2 = (1 + |g|^2)^2 \left| \frac{Q}{dg} \right|^2, \quad h = -Q - \overline{Q} + ds^2.
\]

Since \( K \leq 0 \), we can define the \textit{total absolute curvature} as

\[
 TA(f) := \int_M (-K) \, dA \in [0, +\infty].
\]

Then \( TA(f) \) is the area of the image of \( M \) in \( \mathbb{CP}^1 \) of the secondary Gauss map \( g \). \( TA(f) \) is generally not an integer multiple of \( 4\pi \) — for catenoid cousins [Bry, Example 2] and their \( \delta \)-fold covers, \( TA(f) \) admits any positive real number.

For each conformal CMC-1 immersion \( f : M \to H^3 \), there is a holomorphic null immersion \( F : \tilde{M} \to \text{SL}(2, \mathbb{C}) \), the lift of \( f \), satisfying the differential equation

\[
dF = F \left( \begin{array}{cc} g & -g^2 \\ 1 & -g \end{array} \right) \omega, \quad \omega = \frac{Q}{dg},
\]

so that \( f = FF^* \), where \( F^* = \overline{F} \). Here we consider

\[
 H^3 = \text{SL}(2, \mathbb{C}) / \text{SU}(2) = \{ aa^* | a \in \text{SL}(2, \mathbb{C}) \}.
\]

We call a pair \((g, \omega)\) the \textit{Weierstrass data} of \( f \). The lift \( F \) is said to be \textit{null} because \( \det F^{-1} dF \), the pull-back of the Killing form of \( \text{SL}(2, \mathbb{C}) \) by \( F \), vanishes identically on \( M \). Conversely, for a holomorphic null immersion \( F : \tilde{M} \to \text{SL}(2, \mathbb{C}) \), \( f := FF^* \) is a conformal CMC-1 immersion of \( \tilde{M} \) into \( H^3 \). If \( F = (F_{ij}) \), equation (3.6) implies

\[
 g = -\frac{dF_{12}}{dF_{11}} = -\frac{dF_{22}}{dF_{21}},
\]

and it is shown in [Bry] that

\[
 G = \frac{dF_{11}}{dF_{21}} = \frac{dF_{12}}{dF_{22}}.
\]

The inverse matrix \( F^{-1} \) is also a holomorphic null immersion, and produces a new CMC-1 immersion \( f^\# = F^{-1}(F^{-1})^* : \tilde{M} \to H^3 \), called the \textit{dual} of \( f \). The
induced metric $ds^2$ and the Hopf differential $Q^#$ of $f^#$ are

$$ds^2 = (1 + |G|^2)^2 \left| \frac{Q}{dG} \right|^2, \quad Q^# = -Q. \quad (3.9)$$

So $ds^2$ and $Q^#$ are well-defined on $M$ itself, even though $f^#$ might be defined only on $M$. This duality between $f$ and $f^#$ interchanges the roles of the hyperbolic Gauss map $G$ and secondary Gauss map $g$. In particular, one has

$$dF F^{-1} = -(F^{-1})^{-1} d(F^{-1}) = \left( \begin{array}{cc} G^2 & Q \\ 1 & -G \end{array} \right) \frac{dG}{dG}. \quad (3.10)$$

Hence $dF F^{-1}$ is single-valued on $M$, whereas $F^{-1} dF$ generally is not.

Since $ds^2$ is single-valued on $M$, we can define the dual total absolute curvature

$$TA(f^#) := \int_M (-K^#) dA^#, \quad \text{where } K^# (\leq 0) \text{ and } dA^# \text{ are the Gaussian curvature and area element of } ds^2,$$

respectively. As

$$ds^2 := (-K^#) ds^2 = \frac{4 dG dG}{(1 + |G|^2)^2} \quad (3.11)$$

is a pseudo-metric of constant curvature 1 with developing map $G$, $TA(f^#)$ is the area of the image of $G$ on $\mathbb{CP}^1 = S^2$. The following assertion is important for us:

**Lemma 3.1** ([UY2, Yu2]). The Riemannian metric $ds^2$ is complete (resp. non-degenerate) if and only if $ds^2$ is complete (resp. nondegenerate).

We now assume that the induced metric $ds^2$ (and consequently $ds^2$) on $M$ is complete and that either $TA(f) < \infty$ or $TA(f^#) < \infty$, hence there exists a compact Riemann surface $\overline{M}_\gamma$ of genus $\gamma$ and a finite set of points $\{p_1, \ldots, p_n\} \subset \overline{M}_\gamma$ $(n \geq 1)$ so that $M$ is biholomorphic to $\overline{M}_\gamma \setminus \{p_1, \ldots, p_n\}$ (see Theorem 9.1 of [Oss]). We call the points $p_j$ the ends of $f$.

Unlike the Gauss map for minimal surface with $TA(\infty) < \infty$ in $\mathbb{R}^3$, the hyperbolic Gauss map $G$ of the surface might not extend to a meromorphic function on $\overline{M}_\gamma$, as the Enneper cousin (Example 4.2) shows. However, the Hopf differential $Q$ does extend to a meromorphic differential on $\overline{M}_\gamma$ ([Bry]). We say an end $p_j$ $(j = 1, \ldots, n)$ of a CMC-1 immersion is regular if $G$ is meromorphic at $p_j$. When $TA(f) < \infty$, an end $p_j$ is regular precisely when the order of $Q$ at $p_j$ is at least $-2$, and otherwise $G$ has an essential singularity at $p_j$ ([UY1]). Moreover, the pseudometric $ds^2$ as in (1.1) has a conical singularity at each end $p_j$ ([Bry]). For a definition of conical singularity, see Appendix A (see also [UY3, UY2]).

Thus the orders of $Q$ at the ends $p_j$ are important for understanding the geometry of the surface, so we now introduce a notation that reflects this. We say a CMC-1 surface is of type $\Gamma(d_1, \ldots, d_n)$ if it is given as a conformal immersion $f: \overline{M}_\gamma \setminus \{p_1, \ldots, p_n\} \to H^3$, where $\text{ord}_{p_j} Q = d_j$ for $j = 1, \ldots, n$ (for example, if $Q = z^{-2}dz$ at $p_1 = 0$, then $d_1 = -2$). We use $\Gamma$ because it is the capitalized form of $\gamma$, the genus of $\overline{M}_\gamma$. For instance, the class $\Gamma(-4)$ means the class of surfaces of genus 1 with 1 end so that $Q$ has a pole of order 4 at the end, and the class $\Gamma(-2, -3)$ is the class of surfaces of genus 0 with two ends so that $Q$ has a pole of order 2 at one end and a pole of order 3 at the other.
Analogue of the Osserman inequality. For a CMC-1 surface of genus \( \gamma \) with \( n \) ends, the second and third authors showed that the equality of the Cohn-Vossen inequality for the total absolute curvature never holds [UY1]:

\[
\frac{1}{2\pi} \text{TA}(f) > -\chi(M) = 2(\gamma - 2) + n .
\]

The catenoid cousins (Example 4.3) show that this inequality is the best possible.

On the other hand, the dual total absolute curvature satisfies an Osserman-type inequality [UY5]:

\[
\frac{1}{2\pi} \text{TA}(f^\#) \geq -\chi(M) + n = 2(\gamma + n - 1).
\]

Moreover, equality holds exactly when all the ends are embedded: This follows by noting that equality is equivalent to all ends being regular and embedded ([UY5]), and that any embedded end must be regular (proved recently by Collin, Hauswirth and Rosenberg [CHR1]).

Effects of transforming the lift \( F \). Here we consider the change \( \hat{F} = aFb^{-1} \) of the lift \( F \), where \( a, b \in \text{SL}(2, \mathbb{C}) \). Then \( \hat{F} \) is also a holomorphic null immersion, and the hyperbolic Gauss map \( \hat{G} \), the secondary Gauss map \( \hat{g} \) and the Hopf differential \( \hat{Q} \) of \( f = \hat{F}\hat{F}^* \) are given by (see [UY3])

\[
\hat{G} = a \ast G, \quad \hat{g} = b \ast g, \quad \hat{Q} = Q .
\]

In particular, the change \( \hat{F} = aF \) moves the surface by a rigid motion of \( H^3 \), and does not change \( g \) and \( Q \). By choosing a suitable rigid motion \( a \in \text{SL}(2, \mathbb{C}) \) of the surface in \( H^3 \), the expression for \( G \) can often be simplified, using

\[
\hat{G} = a \ast G = \frac{a_{11}G + a_{12}}{a_{21}G + a_{22}}, \quad (a_{ij})_{i,j=1,2} \in \text{SL}(2, \mathbb{C}) .
\]

SU(2)-monodromy conditions. Here we recall from [RUY1] the construction of CMC-1 surfaces with given hyperbolic Gauss map \( G \) and Hopf differential \( Q \).

Let \( \overline{M}_\gamma \) be a compact Riemann surface and \( M := \overline{M}_\gamma \setminus \{p_1, \ldots , p_n\} \). Let \( G \) and \( Q \) be a meromorphic function and meromorphic 2-differential on \( \overline{M}_\gamma \). We assume the pair \((G, Q)\) satisfies the following two compatibility conditions:

\[
\text{For all } q \in M, \text{ord}_q Q = \text{equal to the branching order of } G, \quad \text{and}
\]

\[
\text{for each end } p_j, \text{(branching order of } G) - d_j \geq 2.
\]

The first condition implies that the metric

\[
ds^{2\#} := (1 + |G|^2)^2 \left| \frac{Q}{dG} \right|^2
\]

is non-degenerate at \( q \in M \). The second condition implies that the metric \( ds^{2\#} \) is complete at \( p_j \in \overline{M}_\gamma \) \((j = 1, \ldots , n)\). Our goal is to get a CMC-1 immersion \( f: M \to H^3 \) with hyperbolic Gauss map \( G \) and Hopf differential \( Q \). If such an immersion exists, the induced metric \( ds^2 \) of \( f \) is non-degenerate and complete, by Lemma 3.1.

For a pair \((G, Q)\) satisfying (3.16) and (3.17), we consider the differential equation (3.10). The conditions (3.16) and (3.17) imply that (3.10) may have singularities at \( \{p_1, \ldots , p_n\} \), but is regular on \( M \). Then there exists a solution \( F: \overline{M} \to \text{SL}(2, \mathbb{C}) \), where \( \overline{M} \) is the universal cover of \( M \). Since the solution \( F \)
Figure 1. A horosphere, and fundamental pieces (one-fourth of the surfaces with the ends cut away) of an Enneper cousin and the dual of an Enneper cousin.

of (3.10) is unique up to the change $F \mapsto F_a$ ($a \in \text{SL}(2, \mathbb{C})$), there exists a representation $\rho_F : \pi_1(M) \to \text{SL}(2, \mathbb{C})$ such that

$$F \circ \tau = F\rho_F(\tau) \quad (\tau \in \pi_1(M)).$$

Here we consider an element $\tau$ of the fundamental group $\pi_1(M)$ as a deck transformation on $\tilde{M}$. Thus:

**Proposition 3.2.** If there exists a solution $F : \tilde{M} \to \text{SL}(2, \mathbb{C})$ of (3.10) for $(G, Q)$ satisfying (3.16) and (3.17), then $f := F F^*$ is a complete conformal CMC-1 immersion into $H^3$ which is well-defined on $M$ if $\rho_F(\tau) \in \text{SU}(2)$ for all $\tau \in \pi_1(M)$. Moreover, the hyperbolic Gauss map and the Hopf differential of $f$ are $G$ and $Q$, respectively.

4. Important Examples with $\text{TA}(f)$ or $\text{TA}(f^\#) \leq 8\pi$

In this section, we shall introduce several important CMC-1 surfaces with $\text{TA} \leq 8\pi$ or $\text{TA}(f^\#) \leq 8\pi$.

**Example 4.1 (Horosphere).** A horosphere (see Figure 1) is the only surface of type $O(0)$, with Weierstrass data given by

$$g = 0, \quad \omega = a \, dz \quad (a \in \mathbb{C} \setminus \{0\}).$$

The holomorphic lift $F : \mathbb{C} \to \text{SL}(2, \mathbb{C})$ of the surface with initial condition $F(0) = \text{id}$ is given by

$$F = \begin{pmatrix} 1 & 0 \\ a \, z & 1 \end{pmatrix}.$$  

In particular the hyperbolic Gauss map is a constant function, as well as the secondary Gauss map $g = 0$. This surface is flat and totally umbilic. In particular, the total curvature and the dual total curvature of the surface are both equal to zero. Any flat or totally umbilic CMC-1 surfaces are parts of this surface. Planes in $\mathbb{R}^3$ are the corresponding minimal surfaces with the same Weierstrass data $(g, \omega) = (0, a \, dz)$.

**Example 4.2 (Enneper cousin and dual of Enneper cousin).** The Enneper cousin is given in [Bry], with the same Weierstrass data as the Enneper surface in $\mathbb{R}^3$:

$$g = z, \quad \omega = a \, dz \quad (a \in \mathbb{C} \setminus \{0\}).$$
A catenoid cousin with \( l = 0.8 \), and warped catenoid cousins with \((l, \delta, b) = (4, 1, 1/2)\) and \((1, 2, 1/2)\). The third surface has \( \text{TA}(f) = 4\pi \) because \( l = 1 \) even though its ends are not embedded.

The holomorphic lift \( F: \mathbb{C} \rightarrow \text{SL}(2, \mathbb{C}) \) of the surface with initial condition \( F(0) = \text{id} \) is given by

\[
F = \begin{pmatrix}
\cosh(az) & a^{-1} \sinh(az) - z \cosh(az) \\
a \sinh(az) & a \cosh(az) - az \sinh(az)
\end{pmatrix}.
\]

In particular the hyperbolic Gauss map \( G \) is given by

\[ G = a^{-1} \tanh(az). \]

The Enneper cousin is in the class \( \mathcal{O}(-4) \) and has a complete induced metric of total absolute curvature \( 4\pi \). If one takes the inverse of \( F \), one gets the dual of the Enneper cousin (see Figure 3). Since

\[
F d(F^{-1}) = -dF F^{-1} = \begin{pmatrix}
-a \cosh(az) \sinh(az) & \sinh^2(az) \\
-a^2 \cosh^2(az) & a \cosh(az) \sinh(az)
\end{pmatrix},
\]

the Weierstrass data \((g^#, \omega^#)\) of the dual of the Enneper cousin given by

\[
g^# = a^{-1} \tanh(az), \quad \omega^# = a^2 \cos^2(az) \, dz.
\]

This surface is also in the class \( \mathcal{O}(-4) \) and has a complete induced metric of infinite total absolute curvature (see Lemma 3.1).

**Example 4.3** (Catenoid cousins and warped catenoid cousins). CMC-1 surfaces of type \( \mathcal{O}(-2, -2) \) are classified in Theorem 6.2 in [UY1]. Here we give a slightly refined version given in [RUY4]: A complete conformal CMC-1 immersion \( f: M = \mathbb{C} \setminus \{0\} \rightarrow H^3 \) with regular ends have the following Weierstrass data

\[
g = \frac{\delta^2 - l^2}{4l} z^l + b, \quad \omega = \frac{Q}{dg} = z^{-l-1} dz,
\]

(4.1)
with \( l > 0, \delta \in \mathbb{Z}^+, \) and \( l \neq \delta, \) and \( b \geq 0, \) where the case \( b > 0 \) occurs only when \( l \in \mathbb{Z}^+. \) When \( b = 0 \) and \( \delta = 1, \) the surface is called a catenoid cousin, which is rotationally symmetric. (The Weierstrass data of the catenoid cousin is often written as \( g = z^\mu \) and \( \omega = (1 - \mu^2)z^{-\mu-1}dz/(4\mu). \) This is equivalent to (4.1) for \( b = 0 \) and \( \delta = 1 \) and \( l = \mu \) by a coordinate change \( z \mapsto ((1 - \mu^2)/4\mu)^{(1/\mu)}z. \) Catenoid cousins are embedded when \( 0 < l < 1 \) and have one curve of self-intersection when \( l > 1. \) When \( b = 0, \) \( f \) is a \( \delta \)-fold cover of a catenoid cousin. When \( b > 0 \) (then automatically \( l \) is a positive integer), we call \( f \) a warped catenoid cousin, and its discrete symmetry group is the natural \( \mathbb{Z}_2 \) extension of the dihedral group \( D_1. \)

Furthermore, the warped catenoid cousins can be written explicitly as

\[
 f = FF^*, \quad F = F_0B,
\]

where

\[
 F_0 = \sqrt{\frac{\delta^2 - l^2}{\delta}} \left( \frac{z^{(\delta-l)/2}}{1 - \delta} \frac{\delta - l}{4l} \frac{z^{(l+\delta)/2}}{\delta} - \frac{l}{(l + \delta)} \frac{z^{(l-\delta)/2}}{\delta} \right) \quad \text{and} \quad B = \begin{pmatrix} 1 & -b \\ 0 & 1 \end{pmatrix}.
\]

In particular, the hyperbolic Gauss map and Hopf differential are given by

\[
 G = z^\delta, \quad Q = \frac{\delta^2 - l^2}{4z^2} \frac{dz}{dz},
\]

which are equal to the Gauss map and Hopf differential of the catenoids in \( \mathbb{R}^3. \)

The dual total curvature of a catenoid cousin is \( 4\pi, \) but its total curvature is \( 4\pi l \) \((l > 0), \) which can take any value in \((0, 4\pi) \cup (4\pi, \infty). \) On the other hand, the total absolute curvature and the dual total absolute curvature of warped catenoid cousins are always integer multiples of \( 4\pi. \) (See Figures 2 and 3).

**Example 4.4** (Irreducible trinoids). We take three real numbers \( \mu_1, \mu_2, \mu_3 > -1 \) such that

\[
 (4.2) \quad \cos^2 B_1 + \cos^2 B_2 + \cos^2 B_3 + 2 \cos B_1 \cos B_2 \cos B_3 < 1,
\]

where \( B_j = \pi(\mu_j + 1) \) \((j = 1, 2, 3). \) We also assume

\[
 (4.3) \quad c_1^2 + c_2^2 + c_3^2 - 2(c_1c_2 + c_2c_3 + c_3c_1) \neq 0,
\]

where \( c_j = -\beta_j(\beta_j + 2)/2 \) \( \in \mathbb{R} \) \((j = 1, 2, 3). \) Then it is shown in \([UY7]\) that there exists a unique CMC-1 surface \( f_{\mu_1, \mu_2, \mu_3}: C \setminus \{0, 1\} \to H^3 \) of type \( O(-2, -2, -2) \) such that the pseudometric \( ds^2 = (-K)ds^2 \) defined by (3.1) is irreducible and has

**Figure 4.** Two different CMC-1 trinoids (proven to exist in \([UY3]\)) Although these surfaces are proven to exist, and numerical experiments show that some of them are embedded (as one of the pictures here is), none have yet been proven to be embedded.
conical singularities of orders $\mu_1, \mu_2, \mu_3$ at $z = 0, 1, \infty$, respectively. Moreover, any irreducible CMC-1 surface of type $O(-2, -2, -2)$ whose ends are all embedded is congruent to some $f_{\mu_1, \mu_2, \mu_3}$. All ends of these surfaces are asymptotic to catenoid cousin ends. The inequality (4.2) implies $\mu_1, \mu_2$ and $\mu_3$ are all non-integers.

If we allow equality in (4.2), one of the $\mu_1, \mu_2, \mu_3$ must be an integer. The corresponding CMC-1 surface might not exist for such $\mu_1, \mu_2, \mu_3$ in general [UY7]. If it exists, its induced pseudometric $d\sigma^2$ must be reducible (see Lemmas A.3 and A.4).

The Hopf differential $Q$ of $f_{\mu_1, \mu_2, \mu_3}$ is given by

$$Q = \frac{1}{2} \left( \frac{c_3 z^2 + (c_2 - c_1 - c_3)z + c_1}{z^2(z - 1)^2} \right) dz^2. \tag{4.4}$$

Let $q_1$ and $q_2$ be zeros of $Q$, that is

$$c_3 q_l^2 + (c_2 - c_1 - c_3) q_l + c_1 = 0 \quad (l = 1, 2). \tag{4.5}$$

By (4.3), $q_1 \neq q_2$ holds. The hyperbolic Gauss map is then given by

$$G = \frac{(q_1 - q_2)^2}{2(2z - (q_1 + q_2))}. \tag{4.6}$$

In particular, all of these surfaces have dual total absolute curvature $8\pi$. On the other hand, the total curvature is equal to $2\pi (4 + \mu_1 + \mu_2 + \mu_3)$. If we set $\mu = \mu_1 = \mu_2 = \mu_3$, the condition (4.3) implies that $\mu > -2/3$, and then there exist $f_{\mu, \mu, \mu}$ for any $\mu$ arbitrarily close to $-2/3$, whose total curvatures tend to $4\pi$. This implies Theorem 2.2 is sharp for $m = 1$.

It is interesting to compare these surfaces with minimal trinoids in $R^3$. Minimal trinoids with three catenoid ends are classified in Barbanel [Bar], Lopez [Lo], and Kato [Kat]. Here, we adopt Kato’s notation [Kat]: The Weierstrass data of these trinoids $x_0 : \mathbb{C} \cup \{\infty\} \setminus \{0, p_1, p_2\} \to \mathbb{R}^3$ are given by

$$g = z - \frac{b(p_2^2 p_2^2 + p_1^2 + p_2^2 - p_1 p_2)}{f(z)} , \quad \omega = -f(z)^2 \, dz \quad (b \in \mathbb{R})$$

where $p_1$ and $p_2$ are real numbers such that $(p_1 - p_2)(1 + p_1 p_2) \neq 0$ and

$$f(z) := b \left( \frac{p_1 (z - p_2)}{z - p_1} + \frac{p_2 (p_2 - p_1)}{z - p_2} + \frac{p_1 p_2 (p_1 p_2 + 1)}{z} \right).$$

If the coefficients of $1/z^2$, $1/(z - p_1)^2$, $1/(z - p_2)^2$ in the Laurent expansion of the Hopf differential $Q_0 = \omega \, dg$ at $z = 0, p_1, p_2$ are all the same signature, the
surface is called of type P and otherwise it is called of type N. Type P surface are all Alexandrov-embedded. On the other hand, Type N surfaces are not. (For a definition of Alexandrov embedded, see Cosín and Ros [CR].) These two classes consist of the two connected components of the set of minimal trinoids (Tanaka [Tan]; see Figure 5). In the case of CMC-1 trinoids in $H^3$, we would like to group the surfaces by the signatures of $c_1$, $c_2$, $c_3$. For example, $f_{\mu_1, \mu_2, \mu_3}$ is called of type $(+, +, +)$ if $c_1$, $c_2$, $c_3$ are all positive, and it is called of type $(-, +, +)$ if one of $c_1$, $c_2$, $c_3$ is negative and the other two are positive. By numerical experiment, we se that these four types $(+, +, +), (-, +, +), (-, -, +)$ and $(-, -, -)$ are topologically distinct (see Figure 8). Surfaces of type $(+, +, +)$ have total curvature less than $8\pi$, and it seems that only surfaces in this class can be embedded.
Example 4.5 (4-noids with $\text{TA}(f) < 8\pi$). A CMC-1 surface of genus 0 with 4 ends satisfies the Cohn-Vossen inequality $\text{TA}(f) > 4\pi$ (see (3.13)). Though genus 0 surfaces with an odd number of ends satisfy a sharper inequality (Theorem 2.2), it seems that the Cohn-Vossen inequality is sharp for 4-noids, by numerical experiment: Let $a \in (0, 1)$ be a real number and $M = C \cup \{\infty\} \setminus \{a,-a,a^{-1},-a^{-1}\}$. We set
\[
G := \frac{pz^3 - z}{z^2 - p},
\]
\[
Q := -\frac{\mu(\mu + 2)a^2(a^2 - a^{-2})^2}{(pa^4 - (3p^2 - 1)a^2 + p)(z^2 - a^2)^2(z^2 - a^{-2})^2} dz^2,
\]
where $\mu > -1$ and $p \in R \setminus \{0,1\}$ with $pa^4 - (3p^2 - 1)a^2 + p \neq 0$. If there exists a CMC-1 immersion $f : M \to H^3$ with hyperbolic Gauss map $G$ and Hopf differential $Q$, then
\[
\text{TA}(f) = 4\pi(2\mu + 3).
\]
We shall solve the period problems using the method in \cite{RUY}: Let $D := \{z = re^{i\theta} \in C \mid 0 < r < 1, 0 < \theta < \pi/2\}$. Then the Riemann surface $\tilde{M}$ is obtained by reflection of $D$ about $\partial D$. Let $\tau_1, \tau_2, \tau_3$ and $\tau_4$ be the reflections on the universal cover $\tilde{M}$ of $M$, which are the lifts of the reflections on $M$ about the segment $(0,a)$ on the real axis, the segment $(0,i)$ on the imaginary axis, the unit circle $|z| = 1$, and the segment $(a,1)$ on the real axis, respectively (see Figure 7 left). Let $F : \tilde{M} \to \text{SL}(2,C)$ be a solution of (3.10). Since
\[
G \circ \tau_1 = \sigma_4 \ast G,
\]
\[
Q \circ \tau_j = Q \quad (j = 1, 2, 3, 4)
\]
holds, where
\[
\sigma_1 = \sigma_4 = \text{id}, \quad \sigma_2 = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix},
\]
there exist matrices $\rho_F(\tau_j) \in \text{SL}(2, C)$ ($j = 1, 2, 3, 4$) such that
\[
F \circ \tau_j = \sigma_j F \rho_F(\tau_j) \quad (j = 1, 2, 3, 4).
\]
Moreover, by a similar argument in \cite{RUY} pp. 462–464, one can choose $F$ such that
\[
\rho_F(\tau_1) = \text{id}, \quad \rho_F(\tau_2) = \sigma_2, \quad \rho_F(\tau_j) = \begin{pmatrix} q_j & i\gamma_j^1 \\ i\gamma_j^2 & \bar{q}_j \end{pmatrix} \quad (j = 3, 4),
\]
where $\gamma_j^2 \in R$ and $q_j \bar{q}_j + \gamma_j^2 \gamma_j^2 = 1$. Assume $\gamma_j^1 \gamma_j^2 > 0$. Then there exists a unique solution $F$ of (3.10) such that
\[
\rho_F(\tau_1) = \text{id}, \quad \rho_F(\tau_2) = \sigma_2, \quad \rho_F(\tau_3) = \begin{pmatrix} q & i\gamma \\ i\gamma^* & \bar{q} \end{pmatrix}, \quad \rho_F(\tau_3) = \begin{pmatrix} q_4 & i\gamma_4^1 \\ i\gamma_4^2 & \bar{q}_4 \end{pmatrix}.
\]
For given $\mu$ and $a$, if one can choose $p$ so that $\gamma_4^1 = \gamma_4^2$, that is $\rho_F(\tau_4) \in \text{SU}(2)$, then there exists a CMC-1 immersion $f$ of $M$ into $H^3$ with hyperbolic Gauss map $G$ and Hopf differential $Q$, by Proposition 4.7 in \cite{RUY}.

By numerical calculation, for $\mu = -0.5$ and $a = 0.8$, there exists $p \simeq 1.4$ such that the period problem is solved. This surface thus has $\text{TA}(f) = 8\pi$, and by continuity of the solvability of the period problems, clearly there exist surfaces with $\text{TA}(f) < 8\pi$. Moreover, there exist such parameters $a$ and $p$ for $\mu \simeq -1$. So
it seems that the Cohn-Vossen inequality for genus-zero 4-ended CMC-1 surfaces is sharp. Figure 7 shows the half cut of the surface with $\text{TA}(f^\#) = 5\pi$.

5. The Case $\text{TA}(f^\#) \leq 8\pi$

We now have enough notations and facts (from Section 3) to describe results on the case $\text{TA}(f^\#) \leq 8\pi$ [RUY3].

Let $f: \overline{M}_\gamma \setminus \{p_1, \ldots, p_n\} \to H^3$ be a complete, conformal CMC-1 immersion, where $\overline{M}_\gamma$ is a Riemann surface of genus $\gamma$. Now we assume $\text{TA}(f^\#) \leq 8\pi$. If the hyperbolic Gauss map $G$ has an essential singularity at any end $p_j$, then $\text{TA}(f^\#) = +\infty$, since $\text{TA}(f^\#)$ is the area of the image of $G$. So $G$ is meromorphic on all of $\overline{M}_\gamma$. In particular, $\text{TA}(f^\#) = 4\pi \deg G = 0, 4\pi, \text{ or } 8\pi$.

Since the dual immersion $f^\#$ has finite total curvature, the Hopf differential $Q^\# = -Q$ can be extended to $\overline{M}_\gamma$ as a meromorphic 2-differential [Bry, Proposition 5]. Hence $d_j = \text{ord}_{p_j} Q$ is finite for each $j = 1, \ldots, n$. Our results from [RUY3] are shown in Table 1.

In the table,

- **classified** means the complete list of the surfaces in such a class is known (and this means not only that we know all the possibilities for the form of...
### Table 2. The classification of complete minimal surfaces in $R^3$

| Type       | TA       | The surface                        | c.f.          |
|------------|----------|------------------------------------|---------------|
| O(0)       | 0        | Plane                              |               |

| O(−2, −2, −2) | 8π | [Lop, Theorem 5]                  |               |
| I(−4)      | 8π       | Chen-Gackstatter surface            | [CG]          |

Table 2 shows the corresponding results for minimal surfaces in $R^3$, the classification of complete minimal surfaces with TA $\leq 8\pi$ ([Lop]), for comparison with Table 4.

The data $(G, Q)$, but that we also know exactly for which $(G, Q)$ the period problems of the immersions are solved.

- **classified** means there exists a unique surface (up to isometries of $H^3$ and deformations that come from its reducibility).
- **existence** means that examples exist, but they are not yet classified.
- **existence** means that all possibilities for the data $(G, Q)$ are determined, but the period problems are solved only for special cases.
- **unknown** means that neither existence nor non-existence is known yet.
- **unknown** means that all possibilities for the data $(G, Q)$ are determined, but the period problems are still unsolved.

Any class and type of reducibility not listed in Table 4 cannot contain surfaces with TA$(f^\#) \leq 8\pi$. For example, any irreducible or $H^3$-reducible surface of type $O(−2, −3)$ must have dual total absolute curvature at least $12\pi$.

Table 2 shows the corresponding results for minimal surfaces in $R^3$, the classification of complete minimal surfaces with TA $\leq 8\pi$ ([Lop]). Comparing these two tables, one sees differences between the classes of minimal surfaces with TA $\leq 8\pi$ and the classes of CMC-1 surfaces with TA$(f^\#) \leq 8\pi$. For example, there exist no minimal surfaces of classes $O(−1, −4)$ and $O(−1, −1, −2)$ with TA $\leq 8\pi$, but CMC-1 surfaces of such types do exist.

### 6. Detailed preliminaries

In the remainder of this paper, we shall give new results on the case of higher TA$(f)$. In this section we give further notations and facts that will be needed for this purpose.

For a complete conformal CMC-1 immersion $f: M = \overline{M \setminus \{p_1, \ldots, p_n\}} \rightarrow H^3$ with TA$(f) < \infty$, we define $\mu_j$ and $\mu_j^\#$ to be the branching orders of the Gauss maps $g$ and $G$, respectively, at an end $p_j$. Then the pseudometric $d\sigma^2$ as in (3.1) has a conical singularity of order $\mu_j > -1$ at each end $p_j$ ($j = 1, \ldots, n$). Let
\[ d_j = \text{ord}_{p_j} Q \text{ (j = 1, \ldots, n)}. \] Then an end \( p_j \) is regular if and only if \( d_j \geq -2 \) (see Section 3 or [UY1]). If an end \( p_j \) is irregular, then \( \mu_j^\# = \infty \). At a regular end \( p_j \), the relation (3.5) implies that the Hopf differential \( Q \) expands as

\[ Q = \left( \frac{1}{2} \left( \frac{c_j}{z-p_j} \right)^2 + \ldots \right) \, dz^2, \quad c_j = -\frac{1}{2} \mu_j (\mu_j + 2) + \frac{1}{2} \mu_j^\# (\mu_j^\# + 2), \]

where \( z \) is a local complex coordinate around \( p_j \).

Let \( \{q_1, \ldots, q_m\} \subset M \) be the \( m \) umbilic points of the surface, and let \( \xi_k = \text{ord}_{q_k} Q \). Then, as in (2.5) of [RUY3],

\[ n \sum_{j=1}^n d_j + m \sum_{k=1}^m \xi_k = 4\gamma - 4, \quad \text{in particular,} \quad \sum_{j=1}^n d_j \leq 4\gamma - 4. \]

By (3.4) and (3.5), it holds that

\[ \xi_k = \text{[the branching order of G at q_k] = [the branching order of g at q_k]} = \text{ord}_{q_k} d \sigma^2 = \text{ord}_{q_k} Q. \]

As in (2.4) of [RUY3], the Gauss-Bonnet theorem for \((M_\gamma, d \sigma^2)\) implies

\[ \frac{\text{TA}(f)}{2\pi} = \chi(M_\gamma) + n \sum_{j=1}^n \mu_j + m \sum_{k=1}^m \xi_k = (2\gamma - 2) + n \sum_{j=1}^n \mu_j + m \sum_{k=1}^m \xi_k, \]

as well as

\[ \frac{\text{TA}(f^\#)}{2\pi} = \chi(M_\gamma) + n \sum_{j=1}^n \mu_j^\# + m \sum_{k=1}^m \xi_k, \]

which is obtained from the Gauss-Bonnet theorem for \( d \sigma^2 = (-K^\#) ds^2 \) [RUY3]. Combining this with (6.2), we have

\[ \frac{\text{TA}(f)}{2\pi} = 2\gamma - 2 + n \sum_{j=1}^n (\mu_j - d_j). \]

Proposition 4.1 in [UY1] implies that

\[ \mu_j - d_j > 1, \quad \text{in particular,} \quad \mu_j - d_j \geq 2 \text{ if } \mu_j \in \mathbb{Z}. \]

An end \( p_j \) is regular if and only if \( d_j \geq -2 \), and then \( G \) is meromorphic at \( p_j \). Thus

\[ \mu_j^\# \text{ is a non-negative integer if } d_j \geq -2. \]

By Proposition 4 of [Bry],

\[ \mu_j > -1, \]

hence equation (5.1) implies

\[ \mu_j = \mu_j^\# \quad \text{if } d_j \geq -1. \]

Finally, we note that

\[ \text{any meromorphic function on a Riemann surface } M_\gamma \text{ of genus } \gamma \geq 1 \text{ has at least three distinct branch points.} \]
To prove this, let $\varphi$ be a meromorphic function on $M$, with branch points $\{q_1, \ldots, q_N\}$ with branching order $\psi_k$ at $q_k$. Then the Riemann-Hurwitz relation implies

$$2 \deg \varphi = 2 - 2\gamma + \sum_{k=1}^{N} \psi_k.$$ 

On the other hand, since the multiplicity of $\varphi$ at $q_k$ is $\psi_k + 1$, $\deg \varphi \geq \psi_k + 1$ $(k = 1, \ldots, m)$. Thus

$$(N - 2) \deg \varphi \geq 2(\gamma - 1) + N.$$ 

If $\gamma \geq 1$, then $\deg \varphi \geq 2$, and so $N \geq 3$.

**Remark.** Facts (6.6) and (6.7) imply that, for CMC-1 surfaces, equality never holds in the Cohn-Vossen inequality [UY1]:

$$\frac{\text{TA}(f)}{2\pi} > -\chi(M) = n - 2 + 2\gamma.$$ 

**Construction from two Gauss maps.** In addition to the SU(2)-conditions for the period problem (Proposition 3.2), we introduce another method to construct CMC-1 surfaces ([UY3]): Let $G$ be a meromorphic function on $M$ and $g$ a meromorphic function defined on the universal cover $\tilde{M}$ of $M$. Assume the pseudometric

$$d\sigma^2 := \frac{4dgd\bar{g}}{(1 + gg)\bar{g}}$$

is single-valued on $M$ and has conical singularities at $p_1 \ldots, p_n$. If we set

$$Q := \frac{1}{2}(S(g) - S(G)),$$

then $Q$ is a meromorphic 2-differential on $M$. We assume

$$Q$$

is holomorphic on $M$, and

$$ds^2 := (1 + |g|^2)^2 \left| \frac{Q}{dg} \right|^2$$

is a non-degenerate complete metric on $M$.

Then we have

**Proposition 6.1.** Let $G$ and $g$ be meromorphic functions defined on $M$ and $\tilde{M}$, respectively. If (6.13), (6.14) and (6.15) hold, then there exists a complete CMC-1 immersion $f: M \to H^3$ with hyperbolic Gauss map $G$ and secondary Gauss map $g$.

**Proof.** By (6.13) and (6.12), $\text{ord}_p Q = \text{ord}_p d\sigma^2$ for any point $p \in M$. Then, by Theorem 2.2 and Remark 2.3 in [UY3], there exists a CMC-1 immersion $f: M \to H^3$ whose hyperbolic Gauss map, secondary Gauss map and Hopf differential are $G, g$ and $Q$, respectively. Moreover, by (6.15), the induced metric is complete. 

7. Cases with higher $\text{TA}(f)$

In this section, we investigate CMC-1 surfaces with $\text{TA}(f) \leq 8\pi$. First, we prepare the following lemma.

**Lemma 7.1.** Let $f: M \to H^3$ be a complete CMC-1 immersion of genus $\gamma$ and $n$ ends with $\text{TA}(f) \leq 2\rho\pi$ for some $\rho \in \mathbb{R}^+$. If $f$ is not totally umbilic (not a horosphere), then the following hold:

1. $2\gamma < \rho + 1$ and $1 \leq n < \rho - 2\gamma + 2$. 

(2) If \( n = 1 \), then \( 2\gamma - \rho - 3 < d_1 \leq 4\gamma - 4 \) and \( d_1 \neq -2 \).
(3) If \( \gamma = n = 1 \), then \( -\rho - 1 < d_1 \leq -3 \).
(4) If \( 2 \leq n = \rho + 1 - 2\gamma \), then \( d_j = -2 \) at all ends.
(5) If \( 1 = n = \rho + 1 - 2\gamma \), then \( d_1 \geq 0 \) and \( \mu_1 = 2 + d_1 \).

Proof. By (6.6) and (6.7), we have
\[
(7.1) \quad \rho \geq 2\gamma - 2 + \sum_{j=1}^{n} (\mu_j - d_j) > 2\gamma - 2 + n \geq 2\gamma - 1 ,
\]
which implies the first item of the theorem. In particular, if \( n = 1 \), then equation (7.1) and (6.9) imply \( d_1 > 2\gamma - \rho - 3 \), and since \( d_1 \leq 4\gamma - 4 \) by (6.2) and \( d_1 \neq -2 \) by Corollary 3 of [RY2], the second item of the theorem follows. Even more particularly, if \( \gamma = n = 1 \), then \( -\rho - 1 < d_1 \leq 0 \) and \( d_1 \neq -2 \). But the proof in [RY4] of Theorem 2.1 (in this paper) shows that \( d_1 \) cannot be 0 or \(-1\) as well, implying the third item of the theorem.

Suppose \( n = \rho + 1 - 2\gamma \). Then equation (7.1) implies
\[
(7.2) \quad n + 1 \geq \sum_{j=1}^{n} (\mu_j - d_j ),
\]
and we consider two cases:

Case 1. If \( n \geq 2 \), then (6.7) implies that \( 1 < \mu_j - d_j < 2 \) for all \( j \), so \( \mu_j \notin \mathbb{Z} \) for all \( j \), and hence (6.10) implies that \( d_j \leq -2 \) for all \( j \). But by (7.2) and (6.9), we have \( -2n \leq \sum_{j=1}^{n} d_j \), and so \( d_j = -2 \) for all \( j \).

Case 2. If \( n = 1 \), then
\[
(7.3) \quad 1 < \mu_1 - d_1 \leq 2
\]
holds because of (7.4) and (7.7). Hence by (6.10), \( d_1 \geq -2 \), but Corollary 3 of [RY2] implies \( d_1 \neq -2 \), so \( d_1 \geq -1 \). This implies \( \mu_1 \in \mathbb{Z} \) and \( \mu_1 - d_1 = 2 \), by (6.10) and (7.3).

Suppose \( d_1 = -1 \). Then \( \mu_1^\# = \mu_1 = d_1 + 2 = 1 \), and then by Lemma 3 of [UY3], the only end \( p_1 \) is regular and embedded. Then Corollary 5 of [RY2] implies that the end has nonzero flux, contradicting Theorem 1 of [RY2], so \( d_1 \geq 0 \).

Lemma 7.1 gives the following corollary:

**Corollary 7.2.** If \( f : M \to H^3 \) is a complete CMC-1 immersion with \( \text{TA}(f) \leq 8\pi \), then it is either

1. a surface of genus 0 with at most 5 ends. (If it has 5 ends, then all 5 ends are regular with \( d_1 = d_2 = d_3 = d_4 = d_5 = -2 \), or
2. a surface of genus 1 with at most 3 ends (if it has 3 ends, then all 3 ends are regular with \( d_1 = d_2 = d_3 = -2 \); if it has 1 end, then the end is irregular with \( d_1 = -3 \) or \( d_1 = -4 \)).

Proof. We only have to show that a CMC-1 surface with \( \text{TA}(f) \leq 8\pi \) of genus 2 and with 1 regular end satisfying \( 0 \leq d_1 \leq 4 \) cannot exist. By (6.6), (6.10) and (6.5), such a surface would satisfy \( \text{TA}(f^\#) = \text{TA}(f) \leq 8\pi \) and hence the hyperbolic Gauss map \( G \) is a meromorphic function on a compact Riemann surface \( \overline{M}_2 \) of genus 2 with \( \deg G \leq 2 \). Therefore \( \mu_1^\# \) can be only 0 or 1, and so \( d_1 \leq \mu_1^\# - 2 < 0 \), a contradiction. 

\[ \square \]
### Table 3. Classification of CMC-1 surfaces in $H^3$ with $TA(f) \leq 8\pi$

| Type  | $TA(f)$ | Reducibility | Status | cf. |
|-------|---------|--------------|--------|-----|
| $O(0)$ | 0       | $H^4$-red.   | classified | Horosphere |
| $O(-4)$ | $4\pi$ | $H^4$-red.   | classified | Enneper cousins $\text{[Bry]}$ |
| $O(-5)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case |
| $O(-6)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case |
| $O(-2,-2)$ | $[0,8\pi]$ | $H^4$-red.   | classified | Catenoid cousins and their $\delta$-fold covers $\text{[Bry, Ex. 2],[UY1]}$ |
| $O(-2,-2)$ | $4\pi$ | $H^4$-red.   | classified | Warped cat. cons. $l = 1$ |
|          | $8\pi$ | $H^4$-red.   | classified | Warped cat. cons. $l = 2$ $\text{[UY1,Thm 6.2], Exa. 4.3}$ |
| $O(-1,-4)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case |
| $O(-2,-4)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case $\text{Remark 7.4}$ |
|          | $8\pi$ | $H^4$-red.   | existence | Remarks $7.6,7.7$ |
| $O(-3,-3)$ | $8\pi$ | reducible    | unknown  | Remark 7.6 |
| $O(-3,-4)$ | $8\pi$ | reducible    | unknown  | Remark 7.7 |
| $O(0,-2,-2)$ | $(4\pi,8\pi)$ | $H^4$-red.   | classified | Proposition $7.10$ |
| $O(-1,-2,-3)$ | $8\pi$ | $H^4$-red.   | unknown  | $\text{[UY6]}$ |
| $O(-1,-1,-2)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case |
| $O(-1,-2,-2)$ | $8\pi$ | $H^4$-red.   | classified | Same as “dual” case $\text{Proposition 7.11}$ |
|          | $8\pi$ | $H^4$-red.   | classified | $\text{Proposition 7.12}$ |
| $O(-2,-2,-2)$ | $(4\pi,8\pi)$ | existence    | Classified for irred. embedded end case $\text{[UY6]}$ |
| $O(-2,-2,-3)$ | $8\pi$ | irred./$H^4$-red. | unknown  | $\text{[UY6]}$ |
| $O(-2,-2,-4)$ | $8\pi$ | irred./$H^4$-red. | unknown  | $\text{[UY6]}$ |
| $O(-2,-3,-3)$ | $8\pi$ | irred./$H^4$-red. | unknown  | $\text{[UY6]}$ |
| $O(-2,-2,-2,-2)$ | $8\pi$ | existence    | Example $1.3$ |
| $O(-2,-2,-2,0)$ | $8\pi$ | existence    | Remark $7.14$ |
| $O(-2,-2,-2,d)$ | $8\pi$ | when $d = 3,-2,-1,1$ | unknown | $\text{Remark 7.14}$ |
|          |       | when $d \geq -1$ | unknown | $\text{Remark 7.14}$ |
| $O(-2,-2,-2,-2,-2)$ | $8\pi$ | unknown | Remark $7.13$ |
| $I(-3)$ | $8\pi$ | unknown |
| $I(-4)$ | $8\pi$ | unknown |
| $I(-1,-1)$ | $8\pi$ | unknown |
| $I(-2,-2)$ | $8\pi$ | unknown |
| $I(-2,-3)$ | $8\pi$ | unknown |
| $I(-2,-2,-2)$ | $8\pi$ | unknown |

Now we compile an unfinished classification of CMC-1 surfaces with $TA(f) \leq 8\pi$ (see Table 3). In the “status” column of the table, classified means that the surfaces of such a class are completely classified (i.e. not only is the holomorphic data known, but the period problems are also completely solved), existence means that there exists such a surface, and unknown means that it is unknown if such a surface exists. Surfaces of any type not appearing in the table cannot exist with $TA(f) \leq 8\pi$. 
The case $(\gamma, n) = (0, 1)$. In this case, we may assume $M = C$ and the only end is $p_1 = \infty$. Since $M$ is simply-connected, the representation $\rho_2$ as in (6.3) is trivial, that is, such a surface is $\mathcal{H}^3$-reducible. Then by Lemma 4.9 in Appendix A, the dual immersion $f^\#$ is also well-defined on $M$. And since the dual surface of $f^\#$ is $f$ itself, the classification reduces to that for CMC-1 surfaces with dual absolute total curvature at most $8\pi$, which is done in [1].

The case $(\gamma, n) = (0, 2)$. In this case, the pseudometric $ds^2$ as in (6.1) has the divisor

$$\mu_1 p_1 + \mu_2 p_2 + \xi_1 q_1 + \cdots + \xi_m q_m$$

(see equation (A.9) in Appendix A), where $p_1$ and $p_2$ are ends and $q_1, \ldots, q_m$ are umbilic points. Since $\xi_k (k = 1, \ldots, m)$ are integers, Lemma 4.3 in Appendix A implies that a surface in this class satisfies either

$$(7.4) \quad \mu_1 \in \mathbb{Z} \quad \text{and} \quad \mu_2 \in \mathbb{Z} \quad (\mathcal{H}^3\text{-reducible})$$

or

$$(7.5) \quad \mu_1 \notin \mathbb{Z} \quad \text{and} \quad \mu_2 \notin \mathbb{Z} \quad (\mathcal{H}^1\text{-reducible}).$$

If both ends are regular, such surfaces are completely classified (see Example 4.3 or [UY1]), and the only possible case is $O(-2, -2)$.

So we may assume at least one end is irregular: $d_2 \leq -3$. If $d_1 \geq -1$, then $\mu_1 \in \mathbb{Z}$ by (6.10), and hence we have the case (7.4). In particular $\mu_2 \in \mathbb{Z}$. Hence $g$ is a meromorphic function on the genus 0 Riemann surface $\overline{M}_0 = C \cup \{\infty\}$, and $\text{TA}(f) = 4\pi \deg g$. Thus $\deg g \leq 2$, and hence $\mu_1$ and $\mu_2$ are 0 or 1. Then by (6.7), we have $d_1 \leq -1$ and $\mu_1 = 1$. Moreover, by (6.6), we have $d_2 \geq -4$. On the other hand, if $d_1 \leq -2$, by (6.2), (6.6) and (6.9), we have $-7 \leq d_1 + d_2 \leq -4$.

Hence the possible cases are $(d_1, d_2) = (-1, -3), (-1, -4), (-2, -3), (-2, -4), (-2, -5), (-3, -3)$ and $(-3, -4)$.

Throughout this subsection, we set $M = C \setminus \{0\}$. Thus the two ends are $p_1 = 0$ and $p_2 = \infty$. Here, it holds that

Proposition 7.3. There exists no complete CMC-1 immersion $f : C \setminus \{0\} \to H^3$ with $\text{TA}(f) \leq 8\pi$ and of class $O(-1, -3)$ or $O(-2, -3)$.

Proof. Assume $f$ is of class $O(-1, -3)$. In this case, $\mu_1 \in \mathbb{Z}$ by (6.10), and then $f$ is $\mathcal{H}^3$-reducible (the case of (7.4)). Then by Lemma 4.3 in Appendix A, the dual immersion $f^\#$ is also well-defined on $M$, with dual absolute total curvature $\text{TA}(f^\#) = \text{TA}(f) \leq 8\pi$. Such a surface cannot exist because of the results in [1].

Now suppose $f$ is of class $O(-2, -3)$. If $\mu_1 \in \mathbb{Z}$, then for the same reason as in the $O(-1, -3)$ case, such a surface does not exist. Now assume $\mu_1 \notin \mathbb{Z}$. Then the surface is in class (7.5): $\mu_2 \in \mathbb{Z}$. By the same argument as in the case $d_1 + d_2 = -5$ of $(\gamma, n) = (0, 2)$ in the proof in [1] of Theorem 2.1, such a surface cannot exist.

Using Lemma 4.9 in Appendix A, if $\mu_1 \in \mathbb{Z}$, the classification is the same as the dual case in [1]. Hence the case $O(-1, -4)$, and also the case $O(-2, -4)$ with $\mu_1 \in \mathbb{Z}$ ($\mathcal{H}^3$-reducible), are classified. Furthermore, for the same reason, the $O(-2, -5)$ case with $\mu_1 \in \mathbb{Z}$ and $\text{TA}(f) \leq 8\pi$ does not exist.
Remark 7.4. In the case $O(-2, -4)$ with (7.3) holding, we have the following examples: Let
\[ dg = t z^\mu \frac{z^2 - a^2}{(z^2 - 1)^2} \, dz, \quad Q = \theta \frac{z^2 - a^2}{z^2} \, dz^2, \]
where\[ a^2 = \frac{\mu + 1}{\mu - 1}, \quad \theta = \frac{\mu(\mu + 2)(\mu - 1)}{4(\mu + 1)}, \quad -1 < \mu < 0. \]
Here $t$ is a positive real number corresponding to the one parameter deformation coming from reducibility (see Appendix A). Then the residues of $dg$ at $-1$ and $1$ vanish, and there exists the secondary Gauss map $g$ defined on the universal cover of $M = \mathbb{C} \setminus \{0\}$ (see Remark A.8 in Appendix A). We set $\omega = Q/dg$. Then by Theorem 2.4 in [UY1], one can check that there exists an immersion $f: \mathbb{C} \setminus \{0\} \to H^3$ with data $(g, Q)$. For this example,
\[ \mu_1 = \mu_2 = |\mu + 1| - 1 = \mu \]
because $-1 < \mu < 0$ (see Corollary A.7 in Appendix A). Then,
\[ \frac{\text{TA}(f)}{2\pi} = 2(\mu + 2) \in (4\pi, 8\pi). \]

Remark 7.5. For the $O(-2, -5)$ case, the following data gives examples: We set
\[ dg = t z^\mu \frac{z^3 - a^3}{(z^3 - 1)^2} \, dz, \quad Q = \theta \frac{z^3 - a^3}{z^2} \, dz^2, \]
where\[ a^3 = \frac{\mu + 1}{\mu - 2}, \quad \theta = \frac{\mu(\mu^2 - 4)}{4(\mu + 1)}, \]
and $\mu \in \mathbb{R} \setminus \{0, -1, \pm 2\}, t \in \mathbb{R}^+$. Here $t$ is a parameter corresponding to a deformation which comes from reducibility (see Appendix A). The ends are $z = 0, \infty$ and the umbilic points are $z = a, ae^{2\pi/3i}, ae^{4\pi/3i}$.

In this case, we have $\mu_1 = |\mu + 1| - 1$ and $\mu_2 = |\mu| - 1$. Hence
\[ \mu_1 + \mu_2 = |\mu + 1| + |\mu| - 2 \geq -1, \]
where equality holds if and only if $-1 \leq \mu \leq 0$. Hence the total absolute curvature is
\[ \text{TA}(f) = 2\pi(-2 + \mu_1 + \mu_2 - d_1 - d_2) \geq 8\pi \]
and equality holds if and only if $-1 < \mu < 0$.

Remark 7.6. For the cases $O(-3, -3)$ and $O(-3, -4)$, all ends are irregular, and then one cannot solve the period problem immediately.

In the dual total curvature case, a deformation procedure as in [RY1] can be used to construct examples of type $O(-3, -3)$. Unfortunately, this procedure cannot be used here, because the hyperbolic Gauss map is not a rational function.
Remark 7.7. In the cases of $O(-3, -4)$ and $O(-2, -5)$, it can be shown that $TA(f) \geq 8\pi$. In fact, in these cases, the divisor corresponding the pseudometric $d\sigma^2$ is

$$\mu_1 p_1 + \mu_2 p_2 + \sum_{k=1}^{m} \xi_k q_k,$$

where $q_k (k = 1, \ldots, m)$ are umbilic points (see Appendix A), and by (6.2), we have $\xi_1 + \cdots + \xi_m = 3$ is an odd integer. Then by Corollary 4.7 of [RUY4], we have $\mu_1 + \mu_2 \geq -1$. This shows that $TA(f) \geq 8\pi$, and so $TA(f) = 8\pi$.

The case $(\gamma, n) = (0, 3)$. If $\mu_1$, $\mu_2$ and $\mu_3$ are integers, then by Lemmas A.3 and A.9 in Appendix A, the surface is $H^3$-reducible and its dual is also well-defined on $M$ with dual total absolute curvature at most $8\pi$. By [RUY3], such surfaces must be of type $O(-1, -1, -2)$, $O(-1, -2, -2)$, or $O(-2, -2, -2)$, and the first two cases are classified. Also, examples exist in the third case as well [RUY3, Example 4.4]. Moreover, for any surface of type $O(-1, -1, -2)$, $\mu_1$ and $\mu_2$ are integers, by (5.10). Then, by Lemma A.5 in Appendix A, $\mu_3$ is also an integer. Thus, surfaces of type $O(-1, -1, -2)$ must be $H^3$-reducible and are completely classified.

Next, we assume all $\mu_j \in \mathbb{Z}$. Then (6.2), (6.6) and (6.3) imply that $-8 \leq d_1 + d_2 + d_3 \leq -4$, and (6.10) implies that $d_j \leq -2 (j = 1, 2, 3)$. Hence the possible cases are $O(-2, -2, -2)$, $O(-2, -2, -3)$, $O(-2, -2, -4)$ and $O(-2, -3, -3)$. For the case $O(-2, -2, -2)$, that is, for surfaces with three regular ends, the second and third authors classified the irreducible ones with embedded ends ([UY7], see Example 4.4).

For the cases $O(-2, -3, -3)$ and $O(-2, -2, -4)$, the sum of the orders of the umbilic points are an even integer, by (6.3). Then by Corollary 4.7 in [RUY3] and (6.4), we have $TA(f) \geq 8\pi$, hence $TA(f) = 8\pi$.

By Lemma A.3 in Appendix A, there exists no surface with only one non-integer $\mu_j$. Then the remaining case is to assume that one $\mu_j$, say $\mu_1$, is an integer and $\mu_2, \mu_3 \notin \mathbb{Z}$. Then by (6.10), $d_2, d_3 \leq -2$. Also, by (6.6), (3.7) and (3.9), we have $-5 \leq d_2 + d_3$. Hence we have two possibilities: $(d_2, d_3) = (-2, -2)$ or $(d_2, d_3) = (-2, -3)$.

When $(d_2, d_3) = (-2, -2)$, by (3.4) and (3.7), we have $\mu_1 - d_1 = 2$ or 3. And by (6.2), $d_1 \leq 0$. Hence we have the possibilities $O(-3, -2, -2)$, $O(-2, -2, -2)$, $O(-1, -2, -2)$ and $O(0, -2, -2)$.

Similarly, when $(d_2, d_3) = (-2, -3)$, we have $\mu_1 - d_1 = 2$ and $d_1 \leq 1$. Hence the possibilities are $O(-2, -3, -3)$, $O(-1, -2, -3)$, $O(0, -2, -3)$, $O(1, -2, -3)$. In this case, the corresponding divisor of the pseudometric $d\sigma^2$ is

$$\mu_1 p_1 + \mu_2 p_2 + \mu_3 p_3 + \sum_{k=1}^{m} \xi_k q_k = \mu_2 p_2 + \mu_3 p_3 + (2 + d_1) p_1 + \sum_{k=1}^{m} \xi_k q_k,$$

where the $q_k (k = 1, \ldots, m)$ are the umbilic points and $\xi_k$ is the order of $Q$ at $\xi_k$ (see equation A.3 in Appendix A). Here, by (6.2), $\xi_1 + \cdots + \xi_m = 1 - d_1$, so

$$\mu_1 + \sum_{k=1}^{m} \xi_k = d_1 + 2 + \sum_{k=1}^{m} \xi_k = 3.$$
Hence if \( d_1 \geq -1 \) (and so \( \mu_1 \in \mathbb{Z}^+ \)), Corollary 4.7 of [RUY4] implies \( \mu_2 + \mu_3 \geq -1 \). This implies that \( \text{TA}(f) \geq 8\pi \), and so

\[
(7.6) \quad \text{For a surface of type } O(d, -2, -3) \ (d \geq -1), \quad \text{TA}(f) \geq 8\pi.
\]

**Proposition 7.8.** There exists no complete CMC-1 surface \( f \) of type \( O(0, -2, -3) \) with \( \text{TA}(f) \leq 8\pi \).

**Proof.** Assume such an immersion \( f: C \cup \{\infty\} \setminus \{p_1, p_2, p_3\} \to H^3 \) exists. By (6.2), there is the only umbilic point \( q_1 \). We set the ends \((p_1, p_2, p_3) = (0, 1, \infty)\) and the umbilic point \( q_1 = q \in C \setminus \{0, 1\} \). Then the Hopf differential \( Q \) has a zero only at \( q \) with order 1, and two poles at 1 and \( \infty \) with orders 2 and 3, respectively. Thus, \( Q \) is written as

\[
(7.7) \quad Q := \frac{z - q}{(z - 1)^2} \quad (\theta \in C \setminus \{0\}).
\]

On the other hand, by (6.6), (6.8), (6.7) and (6.10), we have \( \mu_1 = 2 \), and

\[
(7.8) \quad -2 < \mu_2 + \mu_3 \leq -1 \quad \text{and} \quad -1 < \mu_j < 0 \quad (j = 2, 3).
\]

The secondary Gauss map branches at \((p_1, p_2, p_3)\) and \( q \) with branch orders 2, \( \mu_2 \), \( \mu_3 \) and 1, respectively. Then by Corollary [A.7], we can take the secondary Gauss map \( g \) such that

\[
(7.9) \quad dg = \frac{z^{\alpha}(z-1)^{\nu}(z-q)^{\beta}}{\prod_{j=1}^{N}(z-a_j)^2} \quad (t \in \mathbb{R} \setminus \{0\}),
\]

where

\[
\nu = \mu_2 \quad \text{or} \quad - \mu_2 - 2, \quad \alpha = 2 \quad \text{or} \quad -4, \quad \beta = 1 \quad \text{or} \quad -3,
\]

and \( a_j \in C \setminus \{0, 1, q\} \ (j = 1, \ldots, N) \) are mutually distinct points.

Without loss of generality, we may assume \( \nu = \mu_2 \) (if not, we can take \( 1/g \) instead of \( g \)). Then by (7.7) in Corollary [A.7], we have

\[
-(\alpha + \beta) - \mu_2 + 2N - 2 = \mu_3 \quad \text{or} \quad - \mu_5 - 2,
\]

so \( \mu_2 + \mu_3 \) or \( \mu_2 - \mu_3 \) is an odd integer. Then by (7.8), we have \( \mu_2 + \mu_3 = -1 \) and \((\alpha, \beta, N) = (2, 1, 2)\) or \( (2, -3, 0) \).

First, we assume \((\alpha, \beta, N) = (2, 1, 2)\), and we set \( \mu_2 = \mu \). Then

\[
(7.10) \quad dg = \frac{z^2(z-1)^{\mu}(z-q)}{(z-a)^2(z-b)^2} \quad (a, b \in C \setminus \{0, 1, q\}, a \neq b).
\]

Such a \( g \) exists if and only if the residues of the right-hand side of (7.10) vanish:

\[
(7.11) \quad \frac{2}{a} + \frac{\mu}{a-1} + \frac{1}{a-q} - \frac{2}{a-b} = 0,
\]

\[
(7.12) \quad \frac{2}{b} + \frac{\mu}{b-1} + \frac{1}{b-q} - \frac{2}{b-a} = 0,
\]

(cf. Remark [A.8] in Appendix [A]. Since \( a \neq b \), these equations are equivalent to (7.11) \( - (7.12) \) and \( b \times (7.11) - a \times (7.12) \):

\[
(7.13) \quad (\mu + 1)(a^2 + b^2) - (\mu q + 1)(a + b) - 2ab + 2q = 0,
\]

\[
(7.14) \quad (\mu + 1)(a + b)ab - 2(\mu q + 2)ab + 2q(a + b) = 0.
\]
On the other hand, let $\omega = Q/dg$, and consider the equation
\begin{equation}
X'' - (\log \hat{\omega})' X' - \hat{Q} X = 0 \quad (\omega = \hat{\omega} dz, \quad Q = \hat{Q} dz^2), \tag{7.15}
\end{equation}
which is named (E.1) in [UY1]. The roots of the indicial equation of (7.15) at $z = 0$ are 0 and $-1$. By Theorem 2.2 of [UY1], the log-term coefficient of (7.15) at $z = 0$ must vanish if the surface exists:
\begin{equation}
\mu + 2 - \frac{2}{a} - \frac{2}{b} = 0. \tag{7.16}
\end{equation}
(See Appendix A of [RUY3] or Appendix A of [UY1]). Here, the solution of equations (7.13), (7.14) and (7.16) is
\begin{equation}
a = b = q = \frac{4}{\mu + 2},
\end{equation}
a contradiction. Hence the case $(\alpha, \beta, N) = (2, 1, 2)$ is impossible.

Next, we consider the case $(\alpha, \beta, N) = (2, -3, 0)$. Then the secondary Gauss map $g$ satisfies
\begin{equation}
dg = t \frac{z^2(z - 1)^\mu}{(z - q)^3} \, dz \quad (t \in \mathbb{C} \setminus \{0\}). \tag{7.17}
\end{equation}
The residue at $z = q$ vanishes if and only if
\begin{equation}
(\mu + 2)(\mu + 1)q^2 - 4(\mu + 1)q + 2 = 0. \tag{7.18}
\end{equation}
On the other hand, in the same way as the first case, the log-term coefficient of (7.15) at $z = 0$ vanishes if and only if
\begin{equation}
\mu + 2 = \frac{4}{q}. \tag{7.19}
\end{equation}
However, there is no pair $(\mu, q)$ satisfying (7.18) and (7.19) simultaneously. Hence this case is also impossible. \hfill \Box

**Proposition 7.9.** There exists no CMC-1 immersion of type $O(1, -2, -3)$ with $\mathrm{TA}(f) \leq 8\pi$.

**Proof.** Assume such an immersion $f: C \cup \{\infty\} \setminus \{p_1, p_2, p_3\} \to H^3$ exists. Then we have $\mathrm{TA}(f) = 8\pi$ because of (7.4), and by (6.9), it holds that
\begin{equation}
\mu_1 = 3 \quad \text{and} \quad \mu_2 + \mu_3 = -1, \quad -1 < \mu_j < 0 \quad (j = 2, 3). \tag{7.20}
\end{equation}
We set $(p_1, p_2, p_3) = (1, 0, \infty)$. Since $\sum d_j = -4$, there are no umbilic points, by (6.2). Then the Hopf differential $Q$ has a pole of order 2 at $z = 0$, a pole of order 3 at $z = \infty$, and a zero of order 1 at $z = 1$. Hence $Q$ is written as
\begin{equation}
Q = \theta \frac{z - 1}{z^2} \, dz^2 \quad (\theta \in \mathbb{C} \setminus \{0\}). \tag{7.21}
\end{equation}
The secondary Gauss map $g$ branches at $0, \infty$ and 1 with orders $\mu_2, \mu_3$ and 3, respectively. Then by Corollary A.7 in Appendix A, $dg$ can be put in the following form:
\begin{equation}
dg = t \frac{z^{\mu_2}}{\prod_{j=1}^{N}(z - a_j)^2} \, dz,
\end{equation}
where $N$ is the number of poles of $Q$. If $\mu_2 = 1$, then $N = 3$. If $\mu_2 = 2$, then $N = 2$. If $\mu_2 = 3$, then $N = 1$. Therefore, we have $N = 1, 2, 3$.

\begin{itemize}
  \item If $N = 1$, then $\mu_2 = 3$, hence $\mu_3 = -1$, and $Q$ is written as
    \begin{equation}
    Q = \theta \frac{z - 1}{z^2} \, dz^2 \quad (\theta \in \mathbb{C} \setminus \{0\}).
    \end{equation}

  \item If $N = 2$, then $\mu_2 = 2$, hence $\mu_3 = -2$, and $Q$ is written as
    \begin{equation}
    Q = \theta \frac{z - 1}{z^2} \, dz^2 \quad (\theta \in \mathbb{C} \setminus \{0\}).
    \end{equation}

  \item If $N = 3$, then $\mu_2 = 1$, hence $\mu_3 = -3$, and $Q$ is written as
    \begin{equation}
    Q = \theta \frac{z - 1}{z^2} \, dz^2 \quad (\theta \in \mathbb{C} \setminus \{0\}).
    \end{equation}
\end{itemize}

Then we have $\mu + 2 = \frac{4}{q}$. However, there is no pair $(\mu, q)$ satisfying (7.18) and (7.19) simultaneously. Hence this case is also impossible. \hfill \Box

where \( a_j \in \mathbb{C} \setminus \{0, 1\} \ (j = 1, \ldots, N) \) are mutually distinct numbers, \( t \) is a positive real number, and \( \alpha = 3 \) or \(-5\), and
\[
-\mu_2 - \alpha + 2N - 2 = \mu_3 \quad \text{or} \quad -\mu_3 - 2.
\]
The second case of (7.22) is impossible because of (7.20). Hence \( 2N = \alpha + 1 \), and then \( \alpha = 3 \) and \( N = 2 \). Thus we have the form
\[
dg = tz^{\mu_2} \frac{(z-1)^3}{(z-a)^2(z-b)^2} dz.
\]
Such a \( g \) exists if the residues at \( z = a \) and \( z = b \) vanish. This is equivalent to
\[
\frac{\mu_1}{a} + \frac{3}{a-1} - \frac{2}{a-b} = 0, \quad \text{and} \quad \frac{\mu_1}{b} + \frac{3}{b-1} - \frac{2}{b-a} = 0.
\]
By direct calculation, we have
\[
a = \frac{-2 + \mu + \mu^2 + \sqrt{2} \sqrt{\mu - \mu^2}}{(\mu + 1)(\mu + 2)},
\]
\[
b = \frac{-2 + \mu + \mu^2 - \sqrt{2} \sqrt{\mu - \mu^2}}{(\mu + 1)(\mu + 2)},
\]
where \( \mu = \mu_2 \).

Consider the equation (E.1) in [UY1] with
\[
\omega = \frac{Q}{dg} = (\text{const.}) z^{-\mu_2-2}(z-1)^{-2}(z-a)^2(z-b)^2 dz.
\]
Then, the indicial equation at \( z = 1 \) has the two roots 0 and \(-1\) with difference 1.
By direct calculation again, the log-term at \( z = 1 \) vanishes if and only if
\[
\mu_1 + 2 - \frac{2}{1-a} - \frac{2}{1-b} = -\frac{1}{3} (\mu_2 + 2) = 0,
\]
which is impossible because \( \mu_2 > -1 \).

**Proposition 7.10.** For a non-zero real number \( \mu \ (-1 < \mu < 0) \) and positive integer \( m \), set
\[
G = z^{m+1} \frac{mz - (m+2)}{(m+2)z-m} \quad \text{and} \quad g = z^{\mu+1} \frac{\mu z - (\mu+2)}{(\mu+2)z-\mu}.
\]
Then there exists a one parameter family of conformal CMC-1 immersions \( f : \mathbb{C} \setminus \{0, 1\} \to H^3 \) of type \( O(0,-2,-2) \) with \( \text{TA}(f) = 4\pi(\mu + 2) \), whose hyperbolic Gauss map and secondary Gauss map are \( G \) and \( tg \ (t \in \mathbb{R}^+) \), respectively.

Conversely, any CMC-1 surface of type \( O(0,-2,-2) \) with \( \text{TA}(f) \leq 8\pi \) is obtained in such a manner. In particular, \( \text{TA}(f) < 8\pi \).

**Proof.** For \( g \) and \( G \) as in (7.24), set
\[
Q := \frac{1}{2} (S(g) - S(G)) = \frac{m(m+2) - \mu(\mu+2)}{4} \frac{dz^2}{z^2}.
\]
Since \( \mu \not\in \mathbb{Z} \), the right-hand side is not identically zero. Hence there exists a CMC-1 immersion \( f : \mathbb{C} \setminus \{0, 1\} \to H^3 \) with hyperbolic Gauss map \( G \), secondary Gauss map \( g \) and Hopf differential \( Q \), by Proposition 6.1. Moreover, one can easily check that \( f \) is complete and of type \( O(0,-2,-2) \) with \( \text{TA}(f) < 8\pi \).

Conversely, suppose such a surface exists. Then without loss of generality, we set \( M = \mathbb{C} \setminus \{0, 1\} \) and \( (p_1, p_2, p_3) = (1, 0, \infty) \). By (5.2), there are no umbilic points.
Then the Hopf differential $Q$ has poles of order 2 at 0 and $\infty$, and has no zeros. Hence we have

$$Q = \frac{\theta}{z^2} dz^2 \quad (\theta \in C \setminus \{0\}) \quad (\theta \in C \setminus \{0\}).$$

Hence the secondary and hyperbolic Gauss maps branch only at the ends. Then by a similar argument as in [UY6], we have

$$Hence the secondary and hyperbolic Gauss maps branch only at the ends. Then by a similar argument as in [UY6], we have

$$S(g) = \frac{c_3 z^2 + (c_1 - c_2 - c_3)z + c_2}{z^2(z - 1)^2} dz^2,$$

$$S(G) = \frac{c_3^# z^2 + (c_1^# - c_2^# - c_3^#)z + c_2^#}{z^2(z - 1)^2} dz^2,$$

where

$$c_j = -\frac{1}{2} \mu_j (\mu_j + 2), \quad \text{and} \quad c_j^# = -\frac{1}{2} \mu_j^# (\mu_j^# + 2) \quad (j = 1, 2, 3).$$

Here, $\mu_1 = \mu_1^#$ because of (10). Hence we have

$$2Q = S(g) - S(G)$$

$$= \left( \frac{c_2 - c_2^#}{z^2} + \frac{(c_2 - c_3) - (c_2^# - c_3^#)}{z} - \frac{(c_2 - c_3) - (c_2^# - c_3^#)}{z - 1} \right) dz^2.$$ 

Thus we have

$$(\mu_2 - \mu_3)(\mu_2 + \mu_3 + 2) = (\mu_2^# - \mu_3^#)(\mu_2^# + \mu_3^# + 2).$$

On the other hand, (6.6), (5.7) and (3.9) imply that $\mu_1 = \mu_1^# = 2$ or 3. If $\mu_1 = 3$, (5.10) implies that $\mu_2 + \mu_3 \leq -1$. Then by (3.9), $-1 < \mu_j < 0$ for $j = 2, 3$. Hence using (7.26), we have

$$1 > |\mu_2 - \mu_3| > |\mu_2^# - \mu_3^#|.$$

Here $\mu_2^#$ and $\mu_3^#$ are integers, hence $\mu_2^# = \mu_3^#$. The hyperbolic Gauss map $G$ is a meromorphic function on $C \cup \{\infty\}$. Then the Riemann-Hurwicz relation implies that

$$Z \ni \deg G = \frac{1}{2} (2 + \mu_1^# + \mu_2^# + \mu_3^#) = \mu_2^# + 2 + \frac{1}{2}.$$

This is impossible, and hence we have $\mu_1 = \mu_1^# = 2$.

When $\mu_1 = \mu_1^# = 2$, by similar arguments, we have $-1 < \mu_j < 1$ ($j = 2, 3$) and $\mu_2 + \mu_3 \leq 0$. This implies that $|\mu_2 - \mu_3| < 2$. Thus by (7.26), we have

$$|\mu_2^# - \mu_3^#| = 0 \quad \text{or} \quad 1.$$ 

We may assume that $\mu_3^# \geq \mu_2^#$ (if not, exchange the ends 0 and $\infty$). Assume $\mu_3^# - \mu_2^# = 1$. In this case, we have

$$Z \ni \deg G = \frac{1}{2} (2 + \mu_1^# + \mu_2^# + \mu_3^#) = \mu_2^# + 2 + \frac{1}{2},$$

which is impossible. Hence, using also (7.26), we have $\mu_3^# - \mu_2^# = \mu_3 - \mu_2 = 0$. Moreover, $\mu_2 + \mu_3 = 2\mu_2 \leq 0$, so $\mu_2 \leq 0$. Putting all this together, we have

$$\mu_1 = \mu_1^# = 2, \quad -1 < \mu_2 = \mu_3 \leq 0, \quad \mu_2^# = \mu_3^#,$$

and

$$Q = \frac{c_2 - c_2^#}{2z^2} dz^2.$$
If \( \mu_2 = 0 \), the secondary Gauss map \( g \) is a meromorphic function on \( C \cup \{ \infty \} \) with only one branch point, which is impossible. Hence \( \mu_2 < 0 \). In this case, the pseudometric \( d\sigma^2 \) branches on the divisor

\[
\mu_1 p_1 + \mu_2 p_2 + \mu_3 p_3
\]
because there are no umbilic points (see equation (A.9) in Appendix A). Thus the secondary Gauss map \( g \) satisfies (7.25). One possibility of such a \( g \) is in the form (7.24) with \( \mu = \mu_2 \). On the other hand, since the surface is \( \mathcal{H}^1 \)-reducible, \( g \) can be normalized as in (7.24) because of Corollary A.7 in Appendix A. Since \( S(G) = S(g) - 2Q \), the Schwarzian derivative of the hyperbolic Gauss map \( G \) is uniquely determined, and \( G \) is determined up to Möbius transformations. Then such a surface is unique, with given \( g \) and \( G \).

\[ \square \]

**Proposition 7.11.** Let \( \mu \in (-1,0) \), \( m \geq 2 \) an integer,

\[
a := \frac{m + \mu + 2}{m - \mu - 2}, \quad p := \frac{a \mu + a - a^2}{\mu + a - 1},
\]
and \( M = C \cup \{ \infty \} \setminus \{0,1,p\} \). Then there exist a meromorphic function \( G \) on \( C \cup \{ \infty \} \) and a meromorphic function \( g \) on the universal cover \( \tilde{M} \) of \( M \) such that

\[
(7.27) \quad dG = z(z-p)^{m-2} \frac{dz}{(z-1)^{m+2}} \quad \text{and} \quad dg = t \frac{z(z-1)^{p}(z-p)^{-m-2}}{(z-a)^2} \quad dz
\]
respectively, where \( t \in \mathbb{R}^+ \), and there exists a complete CMC-1 immersion \( f : M \to H^3 \) whose hyperbolic Gauss map and secondary Gauss map are \( G \) and \( g \), respectively. Moreover \( \text{TA}(f) = 4\pi(\mu + 2) \in (4\pi,8\pi) \).

Conversely, an \( \mathcal{H}^1 \)-reducible complete CMC-1 surface of class \( O(-1,-2,-2) \) with \( \text{TA}(f) < 8\pi \) is obtained in such a way.

**Proof.** The residue of \( dG \) in (7.27) at \( z = 1 \) and the residue of \( dg \) in (7.27) at \( z = a \) vanish. Thus there exist \( G \) and \( g \) such that (7.27) hold. Moreover, by direct calculation, we have

\[
Q := \frac{1}{2} (S(G) - S(G)) = \frac{4m^2(m+2)(\mu+2)}{(m+\mu)^2(2-m+\mu)^2} \frac{dz^2}{z(z-1)^2(z-p)^2}.
\]

Then by Proposition 6.1, there exists a CMC-1 immersion \( f : M \to H^3 \). One can easily check that \( f \) is complete and \( \text{TA}(f) = 4\pi(\mu + 2) \).

Conversely, assume such an immersion \( f \) exists. Then by (6.2), there is only one umbilic point of order one. By (6.7), (5.10), (5.8) and (5.9), we have \( \mu_1 = 1 \) or 2. When \( \mu_1 = 2 \), by Corollary 4.7 of [RUY4], \( \mu_2 + \mu_3 \geq -1 \) holds, and then \( \text{TA}(f) \geq 8\pi \).

Assume \( \mu_1 = 1 \) and \( \text{TA}(f) \leq 8\pi \). If one of \( \mu_j \) \( (j = 2,3) \) is an integer, by Appendix A of [RUY4], the other is also an integer, and hence the surface is \( \mathcal{H}^3 \)-reducible. Thus both \( \mu_2 \) and \( \mu_3 \) are non-integers. By (6.8) and (6.9), we have

\[
(7.28) \quad -2 < \mu_2 + \mu_3 \leq 0, \quad -1 < \mu_j < 1 \quad (j = 2, 3).
\]

Set \( (p_1,p_2,p_3) = (0,1,p) \) and the umbilic point \( q = \infty \). Then the secondary Gauss map \( g \) branches at \( 0,1,p \) and \( \infty \) with orders \( \mu_1, \mu_2, \mu_3 \) and 1, respectively. Then by Corollary A.7 in Appendix A, \( g \) can be chosen in the form

\[
dg = t \frac{(z-1)^{\mu}(z-p)^{\mu_3} z^\alpha}{\prod_{k=1}^{N}(z-a_k)^2} \quad dz \quad (t \in \mathbb{R}^+),
\]
where 
\[ \nu_j = \mu_j \quad \text{or} \quad -\mu_j - 2, \quad \alpha = 1 \quad \text{or} \quad -3, \]
and \( \{a_1, \ldots, a_N\} \subset \mathbb{C} \setminus \{0, 1, p\} \) are mutually distinct points. We may assume \( \nu_2 = \mu_2 \) (if not, take \( 1/g \) instead of \( g \)). Then by (A.8),
\[ -\mu_2 - \nu_3 - \alpha + 2N - 2 = 1 \quad \text{or} \quad -3 \]
holds. This implies that \( \mu_2 + \mu_3 \) or \( \mu_2 - \mu_3 \) is an even integer. Then by (7.28), we have
\[ \mu := \mu_2 = \mu_3 \in (-1, 0), \quad \nu_3 = -\mu - 2, \quad \alpha = 1, \quad \text{and} \quad N = 1. \]
Hence we have
\[ \text{(7.29)} \quad dg = t \frac{z(z-1)^\mu(z-p)^{\mu-2}}{(z-a)^2} \quad (t \in \mathbb{R}^+, \quad a \in \mathbb{C} \setminus \{0, 1, p\}). \]
Such a map \( g \) exists on the universal cover of \( \mathbb{C} \setminus \{0, 1, p\} \) if and only if the residue at \( z = a \) of the right-hand side of (7.29) vanishes, that is, if
\[ \text{(7.30)} \quad p = \frac{a\mu + a - a^2}{a\mu + a - 1}. \]
The Hopf differential of such a surface is written in the form
\[ \text{(7.31)} \quad Q = \frac{\theta dz^2}{z(z-1)^2(z-p)^2} \quad (\theta \in \mathbb{C} \setminus \{0\}) \]
because it has poles of order 2 at \( z = 1 \) and \( p \), a pole of order 1 at \( z = 0 \) and a zero of order 1 at \( z = \infty \). Let \( \mu_1^\# \), \( \mu_2^\# \) and \( \mu_3^\# \) be the branch orders of the hyperbolic Gauss map at \( p_1, p_2 \) and \( p_3 \), respectively. Then by (6.1), we have
\[ \text{(7.32)} \quad c_2 - c_2^\# = \frac{2\theta}{(1-p)^2}, \quad c_3 - c_3^\# = \frac{2\theta}{(1-p)^2p}, \]
where
\[ c_2 = c_3 = - \frac{1}{2} \mu(\mu + 2) > 0 \quad \text{and} \quad c_j^\# = - \frac{1}{2} \mu_j^\#(\mu_j^\# + 2) \leq 0 \quad (j = 2, 3). \]
Then \( p \) and \( \theta \) are positive real numbers. Without loss of generality, we may assume \( \mu_2^\# \geq \mu_3^\# \). Then we have
\[ \text{(7.33)} \quad 0 \geq c_2^\# - c_3^\# = \frac{2\theta}{p(1-p)}. \]
Hence \( \mu_2^\# \neq \mu_3^\#, \) that is, \( \mu_2^\# > \mu_3^\# \). Since \( \mu_1^\# = 1 \) by (5.10), the hyperbolic Gauss map branches at 0, 1, \( p \) and \( \infty \) with branching order 1, \( \mu_2^\#, \mu_3^\# \) and 1, respectively. Then the Riemann-Hurwicz relation implies that
\[ \text{deg} G = 2 + \frac{\mu_2^\# + \mu_3^\#}{2} < \mu_2^\# + 2. \]
On the other hand, we have \( \text{deg} G \geq \mu_2^\# + 1 \). Hence we have
\[ \text{deg} G = \mu_2^\# + 1 \quad \text{and} \quad \mu_3^\# = \mu_2^\# - 2. \]
We set \( m := \mu_2^\# \). By a suitable Möbius transformation, we may set \( G(p_2) = G(1) = \infty \). Since \( z = 1 \) is a point of multiplicity \( m + 1 \), \( G \) has no pole except \( z = 1 \). Then \( dG \) is written in the form

\[
dG = c z^{(z-p)^m-2} (z-1)^{m+2} \, dz \quad (c \in \mathbb{C} \setminus \{0\}),
\]

and we can choose \( c = 1 \) by a suitable Möbius transformation. Moreover, the Hopf differential \( Q = (S(g) - S(G))/2 \) is as in \((7.35)\) if and only if

\[
a = -\frac{m + \mu + 2}{m - \mu - 2}.
\]

Thus we have the conclusion.

Proposition 7.12. Let \( m \) be a positive integer and \( \mu \in (-1, 0) \) a real number.

1. If \( m \geq 3 \) and

\[
p := \frac{m(m+2) - \mu(\mu+2)}{(m-2)^2 - \mu^2}, \quad \theta := \frac{(\mu-3m+2)(m(m+2) - \mu(\mu+2))}{((m-2)^2 - \mu^2)^2},
\]

then there exists a complete CMC-1 immersion \( f : M := C \cup \{\infty\} \setminus \{0, 1, p\} \to H^3 \) with hyperbolic Gauss map \( G \) and Hopf differential \( Q \) so that

\[
dG = z^2 (z-p)^{m-3} (z-1)^{m+2} \, dz, \quad Q = \frac{\theta}{z(z-1)^{m+2}(z-p)^2} \, dz^2.
\]

2. If \( m \geq 1 \) and

\[
p := \frac{\mu + m + 2}{\mu + m}, \quad \theta := \frac{(m-\mu)(\mu + m + 2)}{(m+\mu)^2},
\]

and \( a := m - \mu \pm \sqrt{9(m-\mu)^2 + 16m(\mu+1) + 16(m+1)} \),

then there exists a complete CMC-1 immersion \( f : M := C \cup \{\infty\} \setminus \{0, 1, p\} \to H^3 \) with hyperbolic Gauss map \( G \) and Hopf differential \( Q \) so that

\[
dG = z^2 (z-p)^{m-1} (z-1)^{m+2} (z-a)^2 \, dz, \quad Q = \frac{\theta}{z(z-1)^{m+2}(z-p)^2} \, dz^2.
\]

In each case, the immersion \( f \) is complete, of type \( O(-1, -2, -2) \), \( H^1 \)-reducible and satisfies \( \mathrm{TA}(f) = 8\pi \).

Conversely, any \( H^1 \)-reducible CMC-1 immersion of class \( O(-1, -2, -2) \) with \( \mathrm{TA}(f) = 8\pi \) is obtained in this way.

Proof. Since the residue of \( dG \) in \((7.35)\) at \( z = 1 \) vanishes, there exists a meromorphic function \( G \) satisfying \((7.35)\). Since the metric

\[
ds^2 := (1 + |G|^2)^2 \left| \frac{Q}{dG} \right|^2
\]

is non-degenerate and complete on \( M := C \cup \{\infty\} \setminus \{0, 1, p\} \). Hence there exists a CMC-1 immersion \( f : \tilde{M} \to H^3 \) with hyperbolic Gauss map \( G \) and Hopf differential \( Q \) as in \((7.35)\). (In fact, there exists a CMC-1 immersion \( f^\# : \tilde{M} \to H^3 \) with Weierstrass data \((G, -Q/dG)\). Then taking the dual yields the desired immersion.) Let \( F \) be the lift of \( f \). Then \( F \) is a solution of \((8.10)\), and there exists a representation \( \rho_F \) as in \((5.18)\).
The components $F_{21}$ and $F_{22}$ of $F$ satisfy the equation (E.1)\# in [RUY3]:

\[(7.38)\quad X'' - (\log(\omega^\#)'')X' + \hat{Q}X = 0, \quad \left(\omega^\# := \hat{\omega}^\# \frac{dz}{d\omega}, \quad Q = \hat{Q}d\omega^2\right).\]

By a direct calculation, the roots of the indicial equation of (7.38) at $z = 0$ are 0 and $-2$, and the log-term coefficient at $z = 0$ vanishes (see Appendix A of [RUY3]). Hence $F_{21}$ and $F_{22}$ are meromorphic on a neighborhood of $z = 0$, and then, the secondary Gauss map $g = -dF_{22}/dF_{21}$ is meromorphic at $z = 0$. Hence, by (A.10), $\rho_F(\tau_1) = \pm \rho_0(\tau_1) = 1d$, where $\rho_F$ is a representation corresponding to the secondary Gauss map $g$, and $\tau_1$ is a deck transformation corresponding to a loop surrounding $z = 0$.

Moreover, the difference of the roots of the indicial equation at $z = 1$ is $\mu + 1 \not\in \mathbb{Z}$. This implies that one can choose the secondary Gauss map $g$ such that $g \circ \tau_2 = e^{2\pi i \mu}g$, where $\tau_2$ is a deck transformation of $\tilde{M}$ corresponding to a loop surrounding $z = 1$. Thus $\rho_F(\tau_2) = \pm \rho_0(\tau_2) = \text{diag}\{e^{\pi i \mu}, e^{-\pi i \mu}\} \in SU(2)$.

Hence the representation $\rho_F$ lies in SU(2), since $\tau_1$ and $\tau_2$ generate the fundamental group of $M$. Then by Proposition 7.2, the immersion $f$ is well-defined on $M$, and by Lemma 3.2, $f$ is a complete immersion. Using (6.1), we have

$$
\mu_1 = 2, \quad \mu_2 = \mu, \quad \mu_3 = -\mu - 1.
$$

Then by (7.4), we have $TA(f) = 8\pi$.

In the second case, we can prove the existence of $f$ in a similar way.

Conversely, we assume a complete $\mathcal{H}^1$-reducible immersion $f: M \to H^3$ of type $O(-1, -2, -2)$ with $TA(f) = 8\pi$ exists. Without loss of generality, we may set $(p_1, p_2, p_3) = (0, 1, p)$ and the only umbilic point $q = \infty$. As shown in the proof of Proposition 7.11, we have $\mu_1 = \mu_4^\# = 2$. Thus, by (6.6) and the assumption $TA(f) = 8\pi$, we have $\mu_2 + \mu_3 = -1$. Hence by (6.9), we can set

$$
\mu_2 = \mu, \quad \mu_3 = -1 - \mu \quad (-1 < \mu < 0).
$$

Without loss of generality, we may assume $\mu_2^\# \geq \mu_3^\#$. Then by the Riemann-Hurwicz relation, we have

\[(7.39)\quad \deg G = \frac{1}{2}(2 + \mu_1^\# + \mu_2^\# + \mu_3^\# + 1) = \frac{5}{2} + \frac{\mu_2^\# + \mu_3^\#}{2} \leq \frac{5}{2} + \mu_2^\#.

On the other hand, $\deg G \geq \mu_2^\# + 1$. Thus we have $\deg G = \mu_2^\# + 1$ or $\mu_2^\# + 2$. We set $m := \mu_2^\#$.

Assume $\deg G = \mu_2^\# + 1 = m + 1$. Then by (7.39), $\mu_3^\# = m - 3$. Hence, the hyperbolic Gauss map $G$ branches at 0, 1, $p$ and $\infty$ with branch orders 2, $m$, $m - 3$ and 1, respectively. By a suitable Möbius transformation, we assume $G(1) = \infty$. The multiplicity of $G$ at $z = 1$ is $m + 1 = \deg G$. Then $G$ has no other poles on $C \cup \{\infty\}$. Thus, $dG$ can be written in the form

$$
dG = c z^2 \frac{(z - p)^{m - 3}}{(z - 1)^{m + 2}} \, dz,
$$

where $c \in C \setminus \{0\}$. By a suitable Möbius transformation, we may set $c = 1$. On the other hand, the Hopf differential $Q$ is written in the form

$$
Q = \frac{\theta}{z(z - 1)^2(z - p)^2} \, dz^2.
$$
because \( f \) is type \( O(-1, -2, -2) \) and \( \infty \) is the umbilic point of order 1. Thus, by (6.1), we have

\[
(7.40) \quad c_2 - c_2^\# = \frac{2\theta}{(1 - p)^2}, \quad c_3 - c_3^\# = \frac{2\theta}{(1 - p)^2 p},
\]

where

\[
c_j = -\frac{1}{2} \mu_j (\mu_j + 2), \quad c_j^\# = -\frac{1}{2} \mu_j^\# (\mu_j^\# + 2) \quad (j = 2, 3).
\]

Thus we have (7.34).

Next, we assume \( \deg G = m + 2 \). Then by (7.39), we have \( \mu_3^\# = m - 1 \). If we set \( G(1) = \infty \), then \( G \) has only one simple pole other than the pole \( z = 1 \), since the multiplicity of \( G \) at \( z = 1 \) is \( m + 1 \). So \( dG \) is written in the form

\[
dG = c z^2 \frac{(z - p)^{m-1}}{(z - 1)^{m+2}(z - a)^2} dz \quad (a \in C \setminus \{0, 1, p\}),
\]

where \( c \in C \setminus \{0\} \), which can be set to \( c = 1 \) by a suitable Möbius transformation. The residue of \( dG \) at \( z = a \) vanishes if and only if

\[
p = \frac{a(m + 1) + a^2}{ma + 2}.
\]

On the other hand, the relation (7.41) also holds in this case. Thus we have (7.30).

**The case** \( (\gamma, n) = (0, 4) \). If two of the \( \mu_j \) are integers, (6.9) and (6.7) imply that \( TA(f) > 8\pi \). So at most one \( \mu_j \) is an integer.

By (6.1), (6.2) and (6.9), we have

\[
-9 \leq d_1 + d_2 + d_3 + d_4 \leq -4.
\]

When all \( \mu_j \not\in \mathbb{Z} \), all \( d_j \leq -2 \). Hence the possible cases are \( O(-2, -2, -2, -3) \) and \( O(-2, -2, -2, -2) \) (see Example 4.5).

Assume \( \mu_1 \geq 0 \) is an integer. Then \( \mu_2, \mu_3, \mu_4 \not\in \mathbb{Z} \) and \( d_2, d_3, d_4 \leq -2 \). In this case, by (6.4) and (6.7), we have

\[
-6 \leq d_2 + d_3 + d_4.
\]

Hence \( d_2 = d_3 = d_4 = -2 \) and \( \mu_1 - d_1 = 2 \). This implies that \( d_1 \geq -2 \). Moreover, by (6.2), we have \( d_1 \leq 2 \). Hence the possible cases are \( O(d, -2, -2, -2) \) with \( -2 \leq d \leq 2 \). Moreover, \( \mu_1 = 2 + d \) holds and there are \( 2 - d \) umbilic points. Then when \( d \geq -1 \), we have \( \mu_1 \in \mathbb{Z}^+ \), and so by Corollary 4.7 in [RUY4], we have \( TA(f) \geq 8\pi \). So \( TA(f) = 8\pi \).

However, the case \( O(2, -2, -2, -2) \) cannot occur:

**Proposition 7.13.** There exist no CMC-1 surfaces in \( H^3 \) of class \( O(2, -2, -2, -2) \) with \( TA(f) \leq 8\pi \).

**Proof.** Assume such an immersion \( f : C \cup \{\infty\} \setminus \{p_1, \ldots, p_4\} \rightarrow H^3 \) exists. Then there are no umbilic points, and by (5.4), (5.7) and (6.9), \( \mu_1 = \mu_1^\# = 4 \) holds.

Let \( G \) be the hyperbolic Gauss map. Then \( \deg G \geq 5 \) because \( \mu_1^\# = 4 \). Hence by the Riemann-Hurwicz relation,

\[
10 \leq 2\deg G = \sum_{j=2}^{4} \mu_j^\# + \mu_1^\# + 2 = \sum_{j=2}^{4} \mu_j^\# + 6
\]
holds. This implies that $\mu_2 + \mu_3 + \mu_4$ is an even number not less than 4:

$$\mu_2 + \mu_3 + \mu_4 = 2l, \quad (l \in \mathbb{Z}, l \geq 2).$$

Since $\text{TA}(f) = 8\pi$, we have

$$\mu_2 + \mu_3 + \mu_4 = -2.$$  \hspace{1cm} (7.42)

Hence by (6.9),

$$-1 < \mu_j < 0 \quad (j = 2, 3, 4).$$  \hspace{1cm} (7.43)

We set

$$p_2 = 0, \quad p_3 = 1, \quad p_4 = -1, \quad p_1 = p \in \mathbb{C} \cup \{\infty\}.$$  \hspace{1cm} (7.44)

We may assume $p_1 \in \mathbb{C}$. (In fact, if $p_1 = \infty$, the Möbius transformation

$$z \mapsto \frac{z - 1}{3z + 1},$$

maps the ends $(p_1, p_2, p_3, p_4) = (\infty, 0, 1, -1)$ to $(1/3, -1, 0, 1)$.)

The Hopf differential can be written as

$$Q = 2\theta^2 \frac{(z - p)^2}{z^2(z^2 - 1)^2} dz^2 \quad (\theta \in \mathbb{C} \setminus \{0\}).$$

By the relation (6.1), we have

$$c_2 - c_2^\# = 4\theta^2 p^2,$$

$$c_3 - c_3^\# = \theta^2 (1 - p)^2,$$

$$c_4 - c_4^\# = \theta^2 (1 + p)^2,$$

where

$$c_j = -\frac{1}{2}\mu_j(\mu_j + 2), \quad c_j^\# = -\frac{1}{2}\mu_j^\# (\mu_j^\# + 2)$$

for $j = 2, 3, 4$. Since $-1 < \mu_j < 0$ and $\mu_j^\#$ is a non-negative integer, we have

$$0 < c_j < \frac{1}{2}, \quad c_j^\# \leq 0,$$

and consequently, $c_j - c_j^\# > 0 \quad (j = 2, 3, 4)$.

Let

$$\alpha_2 = \theta p, \quad \alpha_3 = \frac{1}{2}\theta (1 - p), \quad \alpha_4 = \frac{1}{2}\theta (1 + p).$$

Then

$$4\alpha_2^2 = c_j - c_j^\#,$$

which implies that the $\alpha_j \quad (j = 2, 3, 4)$ are real numbers. And then

$$p = \frac{\alpha_2}{\alpha_3 + \alpha_4}, \quad \theta = \alpha_3 + \alpha_4$$

are real numbers. Here, without loss of generality, we may set $0 < p < 1$. (In fact, if $p < 0$, applying the coordinate change $z \mapsto -z$, we may set $p > 0$. Moreover, if $p > 1$, by the transformation (7.44), we may set $0 < p < 1$.)

We choose the sign of $\theta$ as $\theta > 0$. Then, we have

$$\alpha_2, \quad \alpha_3, \quad \alpha_4 > 0.$$  \hspace{1cm} (7.48)
Moreover, by (7.47), we have
\begin{equation}
\alpha_2 + \alpha_3 = \alpha_4.
\end{equation}

Using this, we have
\begin{equation}
\mu_2^\# , \quad \mu_3^\# \leq \mu_4^\#.
\end{equation}

To prove (7.51), by (7.49) we have \( \alpha_j < \alpha_4 \) for \( j = 2, 3 \). Then \( c_j - c_4^\# < c_4 - c_4^\# \).

Hence by (7.46), \(-c_j^\# < \frac{1}{2} - c_4^\#\). By definition, this implies that
\begin{equation}
\mu_j^\# (\mu_j^\# + 2) < 1 + \mu_4^\# (\mu_4^\# + 2).
\end{equation}

Thus we have
\begin{equation}
(\mu_j^\# - \mu_4^\#)(\mu_j^\# + \mu_4^\# + 2) < 1 \quad \text{for} \quad j = 2, 3.
\end{equation}

As the \( \mu_j^\# \) are non-negative integers, \( \mu_j^\# - \mu_4^\# \leq 0 \), which implies (7.50).

By (7.45) and the definition of \( \alpha_j \), we have
\begin{equation}
\mu_j (\mu_j + 2) = \mu_j^\# (\mu_j^\# + 2) - 8\alpha_j^2 \quad (j = 2, 3, 4).
\end{equation}

Since \( \mu_j \in (-1, 0) \), this implies that
\begin{equation}
\mu_j + 1 = \sqrt{1 + \mu_j^\# (\mu_j^\# + 2) - 8\alpha_j^2} = \sqrt{(\mu_j^\# + 1)^2 - 8\alpha_j^2} \quad (j = 2, 3, 4).
\end{equation}

Now, defining \( m_j := \mu_j^\# + 1 \geq 1 \) (\( j = 2, 3, 4 \)), (7.50) and (7.49) imply
\begin{equation}
m_2, m_3 \leq m_4 \quad \text{and} \quad \alpha_2 + \alpha_3 = \alpha_4.
\end{equation}

Moreover,
\begin{equation}
m_2 + m_3 \neq m_4
\end{equation}
holds. To prove this, if \( m_2 + m_3 = m_4 \), then \( \mu_2^\# + \mu_3^\# + 2 = \mu_4^\# + 1 \). This implies that \( \mu_2^\# + \mu_3^\# + \mu_4^\# \) is an odd number, contradicting (7.41).

Using (7.51) and (7.52), the equality (7.44) is written as
\begin{equation}
\sqrt{m_2^2 - 8\alpha _2^2} + \sqrt{m_3^2 - 8\alpha _3^2} + \sqrt{m_4^2 - 8(\alpha_2 + \alpha_3)^2} = 1.
\end{equation}

We shall prove that (7.54) cannot hold, making a contradiction. Let \( m_2, m_3, m_4 \) be positive integers which satisfy (7.52) and (7.53). Define
\begin{equation}
\varphi(\alpha_2, \alpha_3) := \sqrt{m_2^2 - 8\alpha _2^2} + \sqrt{m_3^2 - 8\alpha _3^2} + \sqrt{m_4^2 - 8(\alpha_2 + \alpha_3)^2}.
\end{equation}

on the closure \( \overline{D} \) of the open domain
\begin{equation}
D := \left\{ (\alpha_2, \alpha_3) : 0 < \alpha_2 < \frac{m_2}{\sqrt{8}}, 0 < \alpha_3 < \frac{m_3}{\sqrt{8}}, 0 < \alpha_2 + \alpha_3 < \frac{m_4}{\sqrt{8}} \right\}
\end{equation}
in the \( \alpha_2 \alpha_3 \)-plane. Then it holds that
\begin{equation}
\varphi(\alpha_2, \alpha_3) > 1 \quad \text{if} \quad (\alpha_2, \alpha_3) \in D.
\end{equation}

To prove this, note that since \( \varphi \) is a continuous function on a compact set \( \overline{D} \), it takes a minimum on \( \overline{D} \). By a direct calculation, we have
\begin{equation}
\frac{\partial \varphi}{\partial \alpha_3} = \frac{-8\alpha_3}{\sqrt{m_2^2 - 8\alpha _2^2}} + \frac{-8\alpha_2 - 8\alpha_3}{\sqrt{m_4^2 - 8(\alpha_2 + \alpha_3)^2}} < 0 \quad \text{on} \quad D.
\end{equation}
So \( \varphi \) does not take its minimum in the interior \( D \) of \( \overline{D} \), but rather on \( \partial D \). Similarly, \( \partial \varphi / \partial \alpha_2 < 0 \) on \( D \), so the minimum occurs at \( (\alpha_2, \alpha_3) = (m_2/\sqrt{8}, m_3/\sqrt{8}) \), where
\[
\varphi(m_2/\sqrt{8}, m_3/\sqrt{8}) = \sqrt{m_2^2 - (m_2 + m_3)^2} \geq 1,
\]
if the line \( \alpha_2 + \alpha_3 = m_4/\sqrt{8} \) does not intersect \( \partial D \). If the line \( \alpha_2 + \alpha_3 = m_4/\sqrt{8} \) does intersect \( \partial D \), then \( m_2 + m_3 > m_4 \) holds, and the minimum occurs somewhere on this line with \( \alpha_2 \) in the interval \( [(m_4 - m_3)/\sqrt{8}, m_2/\sqrt{8}] \). We have
\[
\varphi(\alpha_2, m_4/\sqrt{8} - \alpha_2) = \sqrt{m_2^2 - 8\alpha_2^2 + m_3^2 - 8(m_4/\sqrt{8} - \alpha_2)^2},
\]
which minimizes at the endpoints of the interval \( [(m_4 - m_3)/\sqrt{8}, m_2/\sqrt{8}] \), where its values are
\[
\sqrt{(m_2 + 2)(m_3 + m_4 - m_2)} \quad \text{and} \quad \sqrt{(m_2 + 2)(m_2 + m_4 - m_3)} \geq 1.
\]
Hence \( \varphi > 1 \) on \( D \), contradicting (7.42) and proving the theorem.

**Remark 7.14.** There exist CMC-1 surfaces of class \( O(-2, -2, -2, 0) \) with \( TA(f) = 8\pi \): We set \( p_1 = 1, p_2 = -1, p_3 = \infty, p_4 = 0 \) and \( M := C \cup \{ \infty \} \setminus \{ p_1, p_2, p_3, p_4 \} \). Set
\[
(7.55) \quad dg := \frac{(z^2 - 1)^\mu (z^2 - q^2)z^2}{(z^2 - a^2)^2} \, dz \quad (a, q \in C \setminus \{ 0, 1 \}, a \neq \pm q, \mu \in \mathbb{R})
\]
and
\[
(7.56) \quad Q := \frac{-\mu(\mu + 2)}{q^2 - 1} \frac{z^2 - q^2}{(z^2 - 1)^2} \, dz^2,
\]
where
\[
\frac{2\mu a}{a^2 - 1} + \frac{2a}{a^2 - q^2} + \frac{1}{a} = 0.
\]
Then the residues of \( dg \) at \( z = \pm a \) vanish, and thus, there exists the secondary Gauss map \( g \) as in (7.55).

We assume
\[-1 < \mu < -\frac{1}{2} \quad \text{and} \quad a^2 = -\frac{1 - \mu - q^2}{3 + \mu - 3q^2}.
\]
Then by Theorem 2.4 of \( [UY1] \), there exists a CMC-1 immersion \( f: M \to H^3 \) with given \( g \) and \( Q \). One can check that such an immersion is complete and has \( TA(f) = 8\pi \).

**The case \((\gamma, n) = (0, 5)\).**

**Remark 7.15.** In this case, \( TA(f) = 8\pi \) by Theorem 2.2. By (6.10), it holds that
\[
6 \geq \sum_{j=1}^{5} (\mu_j - d_j).
\]
By (7.7), if some \( \mu_j \in \mathbb{Z} \), the right-hand side is strictly greater than 6. Hence \( \mu_j \notin \mathbb{Z} \) for all \( j \), and then \( d_j \leq -2 \). On the other hand, since \( \mu_j > -1 \),
\[
\sum_{j=1}^{5} d_j \geq -10
\]
holds. Hence all \( d_j = -2 \).
The case of $\gamma = 1$. In this case, part (1) of Lemma 7.1 implies that a surface of this type has at most three ends. Part (3) of Lemma 7.1 implies that if the surface has only one end, then it must be of type $I(-3)$ or $I(-4)$. Part (4) of Lemma 7.1 implies that if the surface has three ends, then it must be of type $I(-2,-2,-2)$. This is also stated in the corollary following Lemma 7.1.

Now suppose there are two ends. By (6.2), (6.6) and (6.9), we have

$$-5 \leq d_1 + d_2 \leq 0. \tag{7.57}$$

Also, by (1.6) and (1.7), $\text{TA}(f) = 8\pi$ if $d_1, d_2 \geq -1$. Suppose that both ends are regular (i.e. $d_1, d_2 \geq -2$). Then Theorem 7 of [RUY2] implies that if $d_1 = -2$, then also $d_2 = -2$. Furthermore, by Lemma 3 of [UY3] combined with (6.6), (6.7) and (6.10), if $d_i \geq -1$, then the end at $p_i$ is embedded. Therefore, when $d_i \geq -1$, Corollary 5 of [RUY2] implies that the flux at the end $p_i$ is zero if and only if $d_j \geq 0$. By the balancing formula Theorem 1 of [RUY2] and Proposition 2 of [RUY2], we conclude that the only possibilities are $I(-2,-2)$, $I(-1,-1)$, and $I(0,0)$. But in fact the case $I(0,0)$ cannot occur, because then (5.2) and (6.3) imply that the hyperbolic Gauss map $G$ has at most two branch points, contradicting (5.11).

If the end $p_1$ is irregular, $d_1 \leq -3$. Then by (7.57), we have $d_2 \geq -2$. In particular, the other end $p_2$ is regular. When $d_2 \geq -1$, then $\mu_1, \mu_2 \in \mathbb{Z}$, and (6.6) and (6.7) imply $\mu_1 - d_1 = \mu_2 - d_2 = 2$. In particular $d_1 = \mu_1 - 2 > -3$, a contradiction. Hence the only possible case is $I(-2,-3)$.

Remark 7.16. The genus one catenoid cousin in [RS] is of type $I(-2,-2)$ (Figure 8). However, the total absolute curvature seems to be strictly greater than $8\pi$.

Remark 7.17. There exists an example of CMC-1 surface of type $I(-2,-2,-2)$, which is so-called the genus one trinoid ([RUY], see Figure 9), which is obtained by deforming minimal surface in $\mathbb{R}^3$. However, the absolute total curvature of the original minimal surface is $12\pi$, so the obtained CMC-1 surface has $\text{TA}(f)$ close to $12\pi$. Thus, surfaces obtained by deformation are far from satisfying $\text{TA}(f) \leq 8\pi$. 

Figure 8. CMC-1 genus 1 catenoid cousin in $H^3$, proven to exist in [RS]. The graphics were made by Katsunori Sato of Tokyo Institute of Technology. No corresponding minimal surface can exist, by Schoen's result [Sch]. Levitt and Rosenberg [LR] have proved that any complete properly embedded CMC-1 surface in $H^3$ with asymptotic boundary consisting of at most two points is a surface of revolution, which implies that this example and the last two examples in Figure 2 cannot be embedded, and we see that they are not.
Figure 9. A CMC-1 genus 1 trinoid in $H^3$ (proven to exist in [RUY1]). The graphics for the genus 1 surface here were made by Katsunori Sato of Tokyo Institute of Technology.

Figure 10. 5 ended CMC-1 surface in $H^3$, found in [UY1]. Here we show only one of six congruent disks that form the surface. The full surface is constructed by reflections across planes containing boundary curves of the disk shown here.

Figure 11. Genus 0 and genus 1 Enneper cousin duals. Each surface has a single end that triply wraps around its limiting point at the south pole of the sphere at infinity. These surfaces are of type $O(-4)$ and $I(-4)$, and have $\text{TA}(f^\#) = 4\pi$ and $\text{TA}(f^\#) = 8\pi$. In both cases only one of four congruent pieces (bounded by planar geodesics) of the surface is shown.

Appendix A. Reducibility

The notion of reducibility plays an important role in classification problems. In this appendix, we summarize it. For details, see [UY3, UY7, RUY1].

Metrics with conical singularities. Let $\overline{M}$ be a compact Riemann surface. A pseudometric $\sigma^2$ on $\overline{M}$ is said to be an element of $\text{Met}_1(\overline{M})$ if there exists a finite set of points $\{p_1, \ldots, p_n\} \subset \overline{M}$ such that

1. $\sigma^2$ is a conformal metric of constant curvature 1 on $\overline{M} \setminus \{p_1, \ldots, p_n\}$, and
Figure 12. A CMC-1 surface in $H^3$, proven to exist in [UY1]. This example is interesting because the hyperbolic Gauss map has an essential singularity at one of its two ends, like the end of the Enneper cousin. And the geometric behavior of the end here is strikingly similar to that of the Enneper cousin’s end (see the middle figure of Figure 1). Here we show three pictures consecutively including more of this end.

Figure 13. CMC-1 “Costa cousin” in $H^3$, proven to exist by Costa and Sousa Neto [CN]. Rather than showing graphics of this surface, we show two vertical cross sections by which the surface is reflectionally symmetric (including the “circles” at infinity), and a schematic of the central portion of the surface.

(2) \( \{p_1, \ldots, p_n\} \) is the set of conical singularities of \( d\sigma^2 \), that is, for each \( j = 1, \ldots, n \), there exists a real number \( \beta_j > -1 \) so that \( d\sigma^2 \) is asymptotic to \( c|z - p_j|^{2\beta_j} \, dz \, d\bar{z} \), where \( z \) is a complex coordinate of \( \tilde{M} \) around \( p_j \) and \( c \) is a positive constant.

We call the real number \( \beta_j \) the order of the conical singularity \( p_j \), and denote \( \beta_j = \text{ord}_{p_j} \, d\sigma^2 \). The formal sum

\[
\beta_1 p_1 + \cdots + \beta_n p_n
\]

(A.1)

is called the divisor corresponding to \( d\sigma^2 \).

Let \( d\sigma^2 \in \text{Met}_1(\tilde{M}) \) with divisor as in (A.1) and set \( M := \tilde{M} \setminus \{p_1, \ldots, p_n\} \). Then there exists a holomorphic map

\[
g: \tilde{M} \to \mathbb{C} \cup \{\infty\} = \mathbb{CP}^1
\]

defined on the universal cover \( \tilde{M} \) of \( M \) such that

\[
d\sigma^2 = \frac{4 \, dg \, d\bar{g}}{(1 + |g|^2)^2} = g^* ds_0^2
\]

(A.2)
where $d\sigma_0^2$ is the Fubini-Study metric of $\mathbb{CP}^1$. We call $g$ the developing map of $d\sigma^2$. The developing map is unique up to Möbius transformations
\begin{equation}
(A.3) \quad g \mapsto a \star g = \frac{a_{11}g + a_{12}}{a_{21}g + a_{22}} \quad a = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} \in \mathrm{PSU}(2),
\end{equation}
where $\mathrm{PSU}(2) = \mathrm{SU}(2)/\{\pm \mathrm{id}\}$. Here we write $a \in \mathrm{PSU}(2)$ as a $2 \times 2$ matrix in $\mathrm{SU}(2)$ and identify $a$ with $-a$.

For each deck transformation $\tau \in \pi_1(M)$ on $\tilde{M}$, $d\sigma^2 = d\sigma^2 \circ \tau$ holds. So there exists a representation
\begin{equation}
(A.4) \quad \rho_\tau : \pi_1(M) \longrightarrow \mathrm{PSU}(2) \quad \text{such that} \quad \rho \circ \tau^{-1} = \rho_\tau(\tau) \star g \quad \text{for} \quad \tau \in \pi_1(M) .
\end{equation}
By a change of $g$ as in $(A.3)$, the corresponding representation changes by conjugation:
\begin{equation}
(A.5) \quad \rho_{a \star g} = a \rho_\tau a^{-1}. 
\end{equation}
Let $\tau_j$ be a deck transformation induced from a small loop on $\overline{M}$ surrounding a singularity $p_j$. Then by $(A.3)$ and $(A.5)$, one can choose the developing map $g$ such that $\rho_\tau(\tau_j)$ is diagonal:
\begin{equation}
\rho_\tau(\tau_j) = \begin{pmatrix} e^{\pi i \nu_j} & 0 \\ 0 & e^{-\pi i \nu_j} \end{pmatrix} \quad (\nu_j \in \mathbb{R}),
\end{equation}
namely, $g \circ \tau_j = e^{2\pi i \nu_j}g$. This implies that $(z - p_j)^{-\nu_j}g$ is single-valued on a neighborhood of $p_j$, where $z$ is a complex coordinate around $p_j$. Then, replacing $\nu_j$ with $\nu_j + m$ ($m \in \mathbb{Z}$) if necessary, we can normalize
\begin{equation}
(g = (z - p_j)^{\nu_j}(g_0 + g_1z + g_2z^2 + \ldots) \quad (g_0 \neq 0) .
\end{equation}
By definition of the order and by equation $(A.2)$, we have
\begin{equation}
\nu_j = \beta_j + 1 \quad \text{or} \quad -\beta_j - 1 .
\end{equation}

\textbf{Definition A.1.} A pseudometric $d\sigma^2 \in \mathrm{Met}_1(\overline{M})$ is called reducible if the representation $\rho_\tau$ can be diagonalized simultaneously, where $g$ is the developing map of $d\sigma^2$. More precisely, a reducible metric $d\sigma^2$ is called $H^3$-reducible if the representation is trivial, and called $H^3$-reducible otherwise. A pseudometric $d\sigma^2$ is called irreducible if it is not reducible.

By definition, a developing map $g$ of an $H^3$-reducible metric is a meromorphic function on $\overline{M}$ itself. Moreover, by $(A.3)$, all conical singularities have integral orders, which coincide with the branching orders of the meromorphic function $g$. In this case, for any $a \in \mathrm{PSL}(2, \mathbb{C})$, $g_a := a \star g$ induces a new metric $d\sigma_a^2 := g_a^*d\sigma_0^2 \in \mathrm{Met}_1(\overline{M})$ with the same divisor as $d\sigma^2$. Since $d\sigma_a^2 = d\sigma^2$ if $a \in \mathrm{PSU}(2)$ by $(A.3)$, we have a non-trivial deformation of $d\sigma^2$ preserving the divisor parametrized by a real 3-dimensional space $H^3 = \mathrm{PSL}(2, \mathbb{C})/\mathrm{PSU}(2)$, which is the hyperbolic 3-space.

On the other hand, assume $d\sigma^2 \in \mathrm{Met}_1(\overline{M})$ is $H^3$-reducible. Then there exists a developing map $g$ such that the image of $\rho_\tau$ consists of diagonal matrices. Let $t$ be a positive real number and set
\begin{equation}
g_t := tg = \begin{pmatrix} t^{1/2} & 0 \\ 0 & t^{-1/2} \end{pmatrix} \star g.
\end{equation}
Then by $(A.3)$, $\rho_{g_t} = \rho_\tau$ holds. Thus, $g_t$ induces a new metric $d\sigma_t^2 \in \mathrm{Met}_1(\overline{M})$. So we have one parameter family of pseudometrics $\{d\sigma_t^2\}$ preserving the corresponding...
A metric $d\sigma^2 \in \text{Met}_1(\overline{M})$ is reducible if and only if there exists a developing map such that $d\log g$ is a meromorphic 1-form on $\overline{M}$.

Proof. Assume $d\sigma^2$ is reducible. Then one can choose the developing map $g$ such that $\rho_g$ is diagonal. Then for each deck transformation $\tau \in \pi_1(M)$,

$$g \circ \tau^{-1} = \begin{pmatrix} e^{i\nu_\tau} & 0 \\ 0 & e^{-i\nu_\tau} \end{pmatrix} \cdot g = e^{2i\nu_\tau} g \quad (\nu_\tau \in R)$$

holds. Hence we have $\log g \circ \tau = g + 2i\theta_\tau$. Differentiating this, $d\log g \circ \tau = d\log g$ holds. Hence $d\log g$ is single-valued on $\overline{M}$.

Conversely, we assume $d\log g$ is well-defined on $\overline{M}$ for a developing map $g$. Then $\log g \circ \tau - \log g$ is a constant. Hence we have $g \circ \tau = \lambda_\tau g$ for some constant $\lambda_\tau$. Then $\rho_g$ is diagonal.

Genus zero case. In this section, we consider pseudometrics on $C \cup \{\infty\}$. Let $d\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ with divisor as in (A.1).

Lemma A.3. A pseudometric $d\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ with divisor as in (A.1) is $\mathcal{H}^1$-reducible if and only if all orders of conical singularities are integers.

Proof. If $d\sigma^2$ is $\mathcal{H}^1$-reducible, then the developing map $g$ is a meromorphic function on $C \cup \{\infty\}$. So the branch orders must all be integers.

Conversely, assume all conical singularities have integral orders. Then by (A.6), $\rho_g(\tau_j) = \pm \text{id}$ for each $j$, where $\tau_j$ is the deck transformation on $M := C \cup \{\infty\} \setminus \{p_1, \ldots, p_n\}$ corresponding to the loop surrounding $p_j$. Since $\pi_1(M)$ is generated by $\tau_1, \ldots, \tau_n$, $\rho_g$ is the trivial representation.

Lemma A.4. Let $d\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ with divisor as in (A.1). Assume the orders $\beta_1$ and $\beta_2$ are not integers, and $\beta_j$ ($j \geq 3$) are integers. Then $d\sigma^2$ is $\mathcal{H}^1$-reducible.

Proof. Let $g$ be a developing map such that $\rho_g(\tau_1)$ is diagonal. Here, as in the proof of the previous lemma, we have $\rho_g(\tau_j) = \pm \text{id}$ ($j \geq 3$). Then we have $\rho_g(\tau_1)\rho_g(\tau_2) = \pm \text{id}$ because $\tau_1 \circ \cdots \circ \tau_n = \text{id}$. Hence $\rho_g(\tau_2)$ is also a diagonal matrix.

Lemma A.5 (RUY4, Proposition A.1]). There exists no metric $d\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ with divisor as in (A.1) such that only one $\beta_j$ is a non-integer and all others are integers.

A developing map of a reducible metric in $\text{Met}_1(C \cup \{\infty\})$ can be written explicitly as follows:

Lemma A.6 (RUY4, Proposition B.1]). Let $d\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ be reducible with divisor as in (A.1). Assume

$$p_n = \infty, \quad \beta_1, \ldots, \beta_m \notin \mathbb{Z}, \quad \beta_{m+1}, \ldots, \beta_{n-1} \in \mathbb{Z}.$$ 

Then there exists a developing map $g$ of $d\sigma^2$ such that

$$g = (z - p_1)^{\nu_1} \cdots (z - p_m)^{\nu_m} r(z) \quad (\nu_1, \ldots, \nu_m \in \mathbb{R} \setminus \mathbb{Z}),$$

where $r(z)$ is a rational function on $C \cup \{\infty\}$.
**Corollary A.7.** Let $\sigma^2 \in \text{Met}_1(C \cup \{\infty\})$ be reducible with divisor as in (A.1) and $p_n = \infty$. Then there exists a developing map $g$ such that

\[(A.7) \quad dg = t \frac{(z-p_1)^{\alpha_1} \cdots (z-p_{n-1})^{\alpha_{n-1}}}{\prod_{k=1}^{r} (z-a_k)^2} dz ,\]

where $\alpha_1, \ldots, \alpha_n \in C \setminus \{p_1, \ldots, p_{n-1}\}$ are mutually distinct, $t$ is a positive real number, and

$$\alpha_j = \beta_j \quad \text{or} \quad -\beta_j - 2 .$$

Moreover, it holds that

\[(A.8) \quad -(\alpha_1 + \cdots + \alpha_{n-1}) + 2N - 2 = \beta_n \quad \text{or} \quad -\beta_n - 2 .\]

**Proof.** If $\sigma^2$ is $H^3$-reducible, $g$ is a meromorphic function on $C \cup \{\infty\}$ which branches at $p_1, \ldots, p_n$ with branch orders $\beta_j \in \mathbb{Z}^+$. Hence $p_j$ is a zero of order $\beta_j$ or a pole of order $\beta_j + 2$ of $dg$ for each $j = 1, \ldots, n$. Let $\{\alpha_1, \ldots, \alpha_N\}$ be the simple poles of $g$ on $C \setminus \{p_1, \ldots, p_{n-1}\}$, then each $a_k$ is a pole of order 2 of $dg$. (The $a_j$ are not branch points of $g$.) The zeros and poles of $dg$ are the branch points and the simple poles of $g$. Hence we have (A.7) for $t \in C \setminus \{0\}$. By a suitable change $g \mapsto e^{i\theta}g$ (which is a special form of the change (A.3)), we can choose $g$ such that $t \in \mathbb{R}^+$. Since $\infty = p_n$ is a zero of order $\beta_n$ or a pole of order $\beta_n + 2$ of $dg$, we have (A.8).

Next we assume $\sigma^2$ is $H^1$-reducible. Without loss of generality, we may assume $\beta_1, \ldots, \beta_m \notin \mathbb{Z}$ and $\beta_{m+1}, \ldots, \beta_{n-1} \in \mathbb{Z}$. Then by Lemma A.6, we can choose the developing map $g$ as

$$g = (z-p_1)^{\nu_1} \cdots (z-p_m)^{\nu_m} r(z) ,$$

where $r(z)$ is a rational function. By (A.4), we have

$$\nu_j = \beta_j + 1 \quad \text{or} \quad -\beta_j - 1 \quad (j = 1, \ldots, m) .$$

Differentiating this, we have

$$dg = (z-p_1)^{\alpha_1} \cdots (z-p_m)^{\alpha_m} r_1(z) dz ,$$

where $r_1(z)$ is a rational function and

$$\alpha_j = \beta_j \quad \text{or} \quad -\beta_j - 2 \quad (j = 1, \ldots, m) .$$

Since each $p_j$ ($j = m+1, \ldots, n-1$) is a branch point of $g$ of order $\beta_j \in \mathbb{Z}$, we have (A.7) by an argument similar to the $H^3$-reducible case. Moreover, since $\text{ord}_\infty \sigma^2 = \beta_n$, we have (A.8). ∎

**Remark A.8.** Let $M = C \cup \{\infty\} \setminus \{p_1, \ldots, p_n\}$, and let $\tilde{M}$ be its universal cover. Then there exists a meromorphic function $g: \tilde{M} \to C \cup \{\infty\}$ satisfying (A.7) if and only if the residues of $dg$ at $\alpha_k$ ($k = 1, \ldots, N$) vanish. This is equivalent to

$$\sum_{j=1}^{n-1} \frac{\alpha_j}{a_l - p_j} - 2 \sum_{k \neq l} \frac{1}{a_l - a_k} = 0 \quad (l = 1, \ldots, N) .$$
Relationship with CMC-1 surfaces. Let $f: \overline{M} \setminus \{p_1, \ldots, p_n\} \to H^3$ be a complete conformal CMC-1 immersion, where $\overline{M}$ is a compact Riemann surface. If $\text{TA}(f) < \infty$, then the pseudometric $d\sigma^2$ as in (3.1) is considered as an element of $\text{Met}_1(\overline{M})$ (see [Br]), and the secondary Gauss map $g$ is the developing map of $d\sigma^2$. By (6.3) in Section 6, the divisor of $d\sigma^2$ is written as
\begin{equation}
\mu_1p_1 + \cdots + \mu_np_n + \xi_1q_1 + \cdots + \xi_mq_m,
\end{equation}
where the $\mu_j$ ($j = 1, \ldots, n$) are the branch orders of $g$ at each $p_j$, the $q_k$ ($k = 1, \ldots, m$) are the umbilic points of $f$, and the $\xi_k \in \mathbb{Z}$ are the branch orders of $g$ at $q_k$ for each $k = 1, \ldots, m$.

Let $F$ be a holomorphic lift of $f$ as in (3.6). Then there exists a representation $\rho_F: \pi_1(M) \to \text{SU}(2)$ as in (3.18). By (3.7), the secondary Gauss map $g$ of $F$ changes as
\[ g \circ \tau^{-1} = \rho_F(\tau) \ast g \]
for each deck transformation $\tau \in \pi_1(M)$. Hence the representation $\rho_g$ defined in (A.4) satisfies
\begin{equation}
\rho_g(\tau) = \pm \rho_F(\tau) \quad (\tau \in \pi_1(M)).
\end{equation}

The immersion $f$ is called $H^3$-reducible (resp. $H^1$-reducible) if the corresponding pseudometric $d\sigma^2$ is $H^3$-reducible (resp. $H^1$-reducible).

Lemma A.9. A CMC-1 immersion $f: M \to H^3$ is $H^3$-reducible if and only if the dual immersion $f^\#$ is well-defined on $M$.

Proof. Let $F$ be a lift of $f$. Then $f^\# = F^{-1}(F^{-1})^*$ is well-defined on $M$ if and only if $\rho_F = \pm \text{id}$. This is equivalent to $\rho_g$ being the trivial representation, by (A.10).
