Tuning electronic and optical properties of monolayer PdSe$_2$ by introducing defects: first-principles calculations

X. W. Zhao$^1$, Z. Yang$^1$, J. T. Guo$^1$, G. C. Hu$^1$, W. W. Yue$^1$, X. B. Yuan$^{1*}$ & J. F. Ren$^{1,2*}$

Based on the density functional theory, the electronic and optical properties of pristine monolayer PdSe$_2$ with Pd or Se vacancy-defect are investigated. Our results show that the Se defect is energetically more favorable than that of Pd defect. The band gap reduces, and some new midgap states appear after the Pd or Se defects are introduced. In terms of the optical properties, the prominent anisotropic characters are remained. The obvious new peaks of the dielectric constant appear after introducing defects. The light absorption in the visible energy range expands based on the appearance of the midgap states induced by the Pd or Se defects. The changes of the refractive index and reflectivity are similar with those of the dielectric constants and the light absorption. The energy loss spectrum of the PdSe$_2$ with Pd or Se defects is obviously different, which can be used to identify different defects in PdSe$_2$. These findings provide effective strategies to tune electronic and optical properties of monolayer PdSe$_2$ by introducing defects.

In the last decades, the successful stripping of graphene greatly stimulates people's interest in the study of two-dimensional (2D) materials$^{1-5}$. However, the zero-band gap of graphene limits its applications in electronics, which leads to the emergence of other 2D materials beyond graphene, such as black phosphorous, boron nitride and transition metal di-chalcogenides (TMDCs)$^{6-11}$. The common formula for TMDCs is MX$_2$, where the M and X represent transition metals and chalcogen, respectively$^{12}$. The favorable band-gap phenomenon together with the excellent chemical properties of TMDCs enable a wide range of application prospects in field-effect transistors, energy storage, catalysis, and so on$^{10,11}$. Besides, several TMDCs have been widely studied both theoretically and experimentally based on their distinguished mechanics, electronics and optical properties, such like MoS$_2$, MoSe$_2$, and WS$_2^{13-15}$. Recently, another class of layered materials formed by noble metals (e.g. Pd and Pt) with S or Se atoms have been widely investigated owing to their unique atomic and electronic structures$^{16,17}$.

Monolayer PdSe$_2$, which is a special 2D material, possesses an uncommon pentagonal structure. Pd atoms coordinate with four Se atoms to form a square backbone network. Monolayer PdSe$_2$ has been successfully exfoliated by Akinola D. Oyedele et al. for the first time, which provides exciting opportunities for the research of pentagonal 2D materials$^{18}$. The air-stability and anisotropy of monolayer PdSe$_2$ have been proved, moreover, few-layered PdSe$_2$ behaves ambipolar semiconducting with high electron-apparent field-effect mobility. In addition, the remarkable electronic structures of PdSe$_2$ are layer-dependent. The monolayer PdSe$_2$ has an indirect band gap about 1.43 eV, while bulk PdSe$_2$ has a band gap of 0.03 eV$^{18,19}$. The promising thermoelectric performance of monolayer PdSe$_2$ has been demonstrated through the density functional theory and semiclassical Boltzmann transport equation by Dan Qin et al. as well$^{20}$. Overall, the discovery of pentagonal PdSe$_2$ makes the emerging physics related to such low-symmetry structure possible. What's more, monolayer PdSe$_2$ can be a promising candidate in the applications of piezoelectrics, valleytronics, optoelectronics and spintronics.

In order to effectively optimize and utilize the excellent properties of 2D materials, various strategies to tune the optical and electronic properties of 2D materials have been adopted, such as the introduction of defects$^{21}$, electric field and strain modulation$^{19,22}$, atom doping and adsorption$^{23,24}$, strain engineering$^{25}$ etc. As we all know, defects can tune the electronic$^{26}$, magnetic$^{27}$, optical properties and enhance the electrochemical activity$^{19,28}$. The

existence of the point defects in semiconductors can efficiently trap free electrons, holes and localize excitons. When it recombines radiatively, the excitons can lead to light emission at energies lower than the band-to-band optical transition energy. On account of tighter localization of the electron wavefunction, the interactions between the defects and excitons become stronger in reduced dimensionality materials. On one hand, for monolayer PdSe₂, it is highly desirable to explore the optical and electronic properties and develop simple and effective strategies to improve them. This will not only help to enhance the performance of device dependent on monolayer PdSe₂ but also contribute to its applications in nanoelectronic devices. On the other hand, Lin et al. have reported that they have synthesized a novel 2D material monolayer PdₓSe₁₋ₓ, which is a fusion of two defective PdSe layers due to the Se vacancies with a certain concentration. They have systematically stated that the monolayer PdₓSe₁₋ₓ has excellent anisotropic electronic and optical properties and is a very promising candidate for photovoltaics. Take these things into account, we can infer that it is valuable to investigate the effects of the defects on the electronic and optical properties of PdSe₂. In this work, we perform the first-principles calculations to investigate the electronic and optical properties of monolayer PdSe₂ with Pd or Se vacancy defects, the Pd or Se defects are introduced by the random elimination of atoms. After introducing defects, obvious changes for electronic and optical properties of PdSe₂ can be obtained.

Results and Discussions

Firstly, the structural parameters of PdSe₂, monolayer, PdSe₂ with Pd or Se defects are calculated. The bond lengths and angles of vacancy-defected PdSe₂ have little changes with the primitive cell, which means that there is only a slight distortion of the system, so the PdSe₂ with a Pd or Se defect is stable. In order to further compare these two defects, the formation energies are obtained through the following equation: $E_{\text{form}} = E_{\text{defect}} - E_{\text{pristine}} \pm \mu_\nu$, where $E_{\text{defect}}$ represents total energies of the relaxed PdSe₂ with Pd or Se defect, $E_{\text{pristine}}$ is the energy of the pristine PdSe₂, $\mu_\nu$ is the chemical potential of the Pd or Se atom defect. The more positive the $E_{\text{form}}$ is, the more difficult for the defect to be formed. From our calculations, it can be obtained that the $E_{\text{form}}$ of PdSe₂ with Se defect is 1.38 eV, while for the PdSe₂ with Pd defect, it is 1.97 eV, so Se defect is the more energetically favorable type. Recent work also has experimentally demonstrated the presence of Se defect in PdSe₂.

To further clarify the effects of defect on the electronic properties of the monolayer PdSe₂, the band structures along high symmetry k-points are depicted in Fig. 1. Figure 1(a–c) represent the band structures with PBE, Fig. 1(d–f) represent the band structures based on HSE06, respectively. By contrast, it can be found that the PBE underestimates the band gap, the HSE06 is more reasonable to calculate the electronic and optical properties, so the HSE06 are adopted in all the following calculations. As shown in Fig. 1(d), the pristine structure of monolayer PdSe₂ has an indirect band gap about 2.25 eV, which is consistent with previous work. However, after introducing Pd or Se defects, the band gaps are 1.43 and 1.91 eV, respectively. It can be observed from Fig. 1(e,f) that the presence of Pd or Se defect leads to some different new midgap states within the energy band gap, which can also be identified by the sharp peaks in the density of states. All the systems remain indirect band gap, and the PdSe₂ with Pd defect still shows semiconductor characteristics. For the PdSe₂ with Se defect, the band of midgap state goes through the Fermi level, the PdSe₂ shows metal characteristics. It is also indicated that introducing defects is a potentially useful strategy to tune the band gap of 2D materials.

The total density of states (TDOS) and projected density of states (PDOS) for pristine PdSe₂, PdSe₂ with Pd or Se defect are shown in Fig. 2. For pristine PdSe₂, it can be found that the dₓ, dᵧ orbital of Pd atoms and the px, pz orbital of Se atoms mainly contribute to the states at conduction band edge, the dz² orbital of Pd atoms and the px, pz orbital of Se atoms mainly contribute to the valence band edge. Besides, there is significant hybridization between Pd d and Se p states. While after introducing the defects, there are some changes, as shown in Fig. 2(b,c). It is obvious that the midgap states are mainly originated from the pₓ and pᵧ orbital of Se atoms in PdSe₂ with Pd defect, while for PdSe₂ with Se defect, the midgap states mainly originate from the dₓ and dᵧ orbital. In general, the appearance of the peaks in the gapped region of the DOS are associated with the midgap states localized around the defects, which arises from the dangling bonds of Pd or Se due to their unsaturated charges, and their strength depends on the different missing atoms. Thus one can identify the types of defect through the PDOS and then characterize the PdSe₂ in order to get expected electronic properties.

Optical properties of the materials are closely connected to its electronic properties. And it is evident from the previous calculations that the defects can alter the electronic properties of monolayer PdSe₂, the change of electronic properties is expected to modify the optical properties. Figure 3(a–c) represent the real parts of the dielectric constant $\varepsilon_1$ for pristine PdSe₂, PdSe₂ with Pd or Se defect, (d–f) represent the corresponding imaginary parts $\varepsilon_2$, respectively. From Fig. 3(a–c), it can be found that the maximum value of $\varepsilon_1$ in x direction for pristine PdSe₂ is about 7.62, however, it reduces to 6.94 and 4.15 for PdSe₂ with Pd or Se defect, respectively. The maximum values are 7.06, 6.41 and 4.02 for pristine PdSe₂, PdSe₂ with Pd or Se defect in y direction of $\varepsilon_1$, which is different from those in x direction. After introducing defect, the maximum value of $\varepsilon_2$ also decreases from 6.03 for pristine PdSe₂ to 5.39 and 3.36 for PdSe₂ with Pd or Se defect in x direction, respectively. It can be found that the change of $\varepsilon_2$ is different as well both in x and y directions, which means that the anisotropy of the optical properties of PdSe₂ remains unchanged. Furthermore, the peaks in the low energy range of dielectric constant correspond to the peaks in the DOS, which mainly due to the new midgap states originated from the defects.

The absorption coefficients $\alpha(\omega)$ for pristine PdSe₂, PdSe₂ with Pd or Se defect have been depicted to reveal the light absorption properties of PdSe₂, which are shown in Fig. 4. The optical absorption spectrum is closely related to the imaginary parts of the dielectric constant. It can be observed that there is no absorption within the energy range of 0 to 2.20 eV for pristine PdSe₂, as shown in Fig. 4(a), which is consistent with the band gap structure in Fig. 1(d). According to the suitable band gap, monolayer PdSe₂ is expected to be a promising candidate for light absorption. Monolayer PdSe₂ exhibits good optical absorption in the visible regions (1.64–3.19 eV) as is shown in Fig. 4(a). After introducing the Pd or Se defect, the absorption is optimized obviously. The optical absorption starts from 0.44 and 0.53 eV for the PdSe₂ with Pd or Se defect, which are shown in Fig. 4(b,c). That is to say, the
optical absorption in low energy region widens, especially in the visible regions. That is benefit from the existence of the Pd or Se defect in PdSe₂, they can create some midgap states, so more new optical transitions can be activated comparing with the case of pristine PdSe₂. In addition, it can be found that the absorption coefficients are different in x and y directions.

Figure 5 shows the refractive index $n(\omega)$ and reflectivity $R(\omega)$ of PdSe₂ systems. The maximum value of $n(\omega)$ for pristine PdSe₂ is about 2.82. There is noticeable change for the maximum $n(\omega)$ of the PdSe₂ with Pd or Se defect compared with that of pristine PdSe₂, it decreases to 2.72 and 2.01. And the new peak of $n(\omega)$ appears in low energy region obviously as shown in Fig. 5(b,c), which is consistent with the dielectric constant. The $R(\omega)$ of PdSe₂ systems are shown in Fig. 5(d–f) respectively. The maximum $R(\omega)$ for the pristine PdSe₂ and PdSe₂ with Pd or Se defects are 0.32, 0.25 and 0.17, respectively. It is obvious that the maximum $R(\omega)$ decreases compared with that in pristine PdSe₂ and there are new peaks in low energy region after introducing Pd and Se defects. All the new peaks in low energy region are related to the new midgap states.

The electron energy loss spectrum $L(\omega)$ have also been depicted for pristine PdSe₂, PdSe₂ with Pd or Se defect, which are shown in Fig. 6(a–c), respectively. By contrast, it can be found that obvious differences occurred due to the introduction of the defects. The $L(\omega)$ starts from 2.31, 0.31 and 0.45 eV for pristine PdSe₂, PdSe₂ with Pd or Se defect, respectively. The first sharp peak of $L(\omega)$ is observed at 5.13, 1.75 and 0.68 eV. Besides, the curves of pristine PdSe₂ and PdSe₂ with Se defect have a tendency of ascending first and descending in succession then
ascending. While the curve of PdSe$_2$ with Pd defect has a tendency of ascending first and descending in succession, and it has relatively dense peaks. The different $L(\omega)$ can be used to identify different defects.

Conclusions
In this work, the electronic and optical properties of pristine PdSe$_2$, PdSe$_2$ with Pd or Se defect are studied through the first-principles calculations based on the density functional theory. The result of the formation energies indicates that Se defect is more energetically favorable compared with that of Pd defect. By calculating the band structures, it is found that the band gap reduces due to the appearing of the new midgap states after introducing Pd or Se defect.
Se defect. The midgap states are originated from the dangling bonds of Pd or Se due to their unsaturated charges. In terms of the optical properties, the dielectric constant and absorption spectrum, refractive index, reflectivity and electron energy loss spectrum have been analyzed. The obvious peaks of the dielectric constant and the absorption spectrum in low energy region can be observed due to the appearance of the new midgap states induced by the Pd or Se defect. And the prominent anisotropic characters are remained. The light absorption area in the visible regions widens after introducing Pd or Se defect compared with that of pristine PdSe₂. The new peaks benefit from the appearance of the midgap states which activate more new optical transitions in the optical spectrum. For the refractive index and reflectivity, the similar changes have been taken place. Furthermore, the difference of the electron energy loss spectrum can be used to identify different defects. All these findings provide effective strategies to tune electronic and optical properties of monolayer PdSe₂, and provide possibilities for monolayer PdSe₂ in the applications of optoelectronics.

Theoretical model and computational details. All our theoretical calculations are performed through VASP (Vienna ab-initio Simulation Package). PAW pseudopotential is used to describe the interaction between ions and electrons. In terms of the energy exchange correlation energy function, the generalized gradient approximation (GGA) in the form of Perdew-Burke-Ernzerhof (PBE) is used. The electronics and optical properties are calculated by the hybrid functional based on the Heyd-Scuseria-Ernzerhof (HSE06) exchange-correlation functional. The cut-off energy is 400 eV in the process of the structural optimizations and calculations. The 11 × 11 × 1 Monkhorst-Pack grid is chosen when calculating the integral in Brillouin zone. Energy convergence is set to less than 10⁻⁴ eV and the convergence accuracy of the nuclear motion is set to less than 0.01 eV/Å. A 3 × 3 × 1 supercell (54 atoms) of PdSe₂ is constructed, as shown in Fig. 7. It is worth noting that the residual strain may exist due to the limit of periodic boundary condition no matter how bigger the supercell is. In order to avoid the interlayer interference, the thickness of the vacuum layer is set to 20 Å.

The optical properties are general evaluated by the dielectric function which are the sum of real and imaginary parts, ε(ω) = ε₁(ω) + iε₂(ω). The imaginary part is calculated by the summation of empty band states using the following equation.

![Figure 5](https://example.com/figure5.png)

**Figure 6.** Electron energy loss spectrum for pristine PdSe₂ (a), PdSe₂ with Pd (b) or Se defect (c), respectively.
where \( \Omega \) represents the volume, \( v \) and \( c \) correspond to the valence and the conduction band respectively, \( \alpha \) and \( \beta \) indicate the Cartesian components, \( e_\alpha \) and \( e_\beta \) are the unit vectors, \( e_{\kappa} \) and \( e_{\kappa'} \) refer to the energy of conduction and valence band respectively, \( u_{\kappa} \) is the cell periodic part of the orbitals at the \( \kappa \)-point. The real part of dielectric constant is calculated by the Kramers-Kronig relation \(^4\),

\[
\varepsilon_r(\omega) = \frac{4\pi^2e^2}{\Omega} \lim_{q \to 0} \frac{1}{q^2} \sum_{\kappa \kappa'} 2\omega\delta(\varepsilon_\kappa - \varepsilon_{\kappa'} - \omega) \times \left( u_{\kappa + \epsilon_\beta}^{*} u_{\kappa} + u_{\kappa}^{*} u_{\kappa + \epsilon_\beta} \right)
\]

\( \text{Equation 1} \)

with \( P \) being the principle value. According to the values of real and imaginary part of the dielectric constant, the optical absorption coefficient \( \alpha(\omega) \), the refractive index \( n(\omega) \), the reflectivity \( R(\omega) \), and the electron energy loss spectroscopy \( L(\omega) \) can be given by \(^4\),

\[
\alpha(\omega) = \frac{\sqrt{2} \omega}{c} \frac{1}{\varepsilon_1(\omega) + \varepsilon_2(\omega) + 1} \left[ \varepsilon_1(\omega) + \varepsilon_2(\omega) \right],
\]

\( \text{Equation 3} \)

\[
n(\omega) = \frac{1}{\sqrt{2}} \frac{1}{\varepsilon_1(\omega) + \varepsilon_2(\omega) + 1} \left[ \varepsilon_1(\omega) + \varepsilon_2(\omega) \right],
\]

\( \text{Equation 4} \)

\[
R(\omega) = \frac{\sqrt{\varepsilon_1(\omega) + \varepsilon_2(\omega)} - 1}{\sqrt{\varepsilon_1(\omega) + \varepsilon_2(\omega)} + 1},
\]

\( \text{Equation 5} \)

\[
L(\omega) = \frac{\varepsilon_2(\omega)}{\varepsilon_1(\omega) + \varepsilon_2(\omega)}.
\]

\( \text{Equation 6} \)
