Abstract
We introduce a formalism for describing holomorphic blocks of 3d quiver gauge theories using networks of Ding-Iohara-Miki algebra intertwiners. Our approach is very direct and gives an explicit identification of the blocks with Dotsenko-Fateev type integrals for q-deformed quiver W-algebras. We also explain how quiver theories corresponding to Dynkin diagrams of superalgebras arise, write down the corresponding partition functions and W-algebras, and explain the connection with supersymmetric Macdonald-Ruijsenaars commuting Hamiltonians.

1 Introduction
Ding-Iohara-Miki (DIM) algebra [1] is a unique and beautiful object. It can be understood as a quantum affinization $U_q(\widehat{\mathfrak{g}})$ of an algebra $\mathfrak{g}$ which is itself an affine algebra, $\mathfrak{g} = \widehat{\mathfrak{g}}_1$, deformed by an additional parameter $t$. Because of the presence of two loops in the construction, the algebra is often called quantum toroidal, and we will denote it by $U_{q,t}(\widehat{\mathfrak{g}}_1)$. DIM algebra is symmetric under the exchange of three parameters $q$, $t^{-1}$ and $\frac{t}{q}$. It has two gradings $(d, d^\perp)$, two central charges $(\gamma, \gamma^\perp)$ (again coming from two loops in the construction) and also an interesting automorphism group $SL(2, \mathbb{Z})$ which acts on them as doublets. We collect the relevant definitions related to DIM algebra and its representations in Appendix A.

In addition to being interesting from purely algebraic and representation theoretic point of view, DIM algebra is extremely relevant for physics. For example:

• It is the symmetry behind the AGT relation [2] between instanton series of 4d $\mathcal{N} = 2$ (and 5d $\mathcal{N} = 1$) gauge theories and 2d CFTs [3], [4], [5]. It is also the origin of the spectral duality, which exchanges the gauge groups at the nodes of a quiver gauge theory with the group corresponding to the Dynkin diagram of the quiver [6], [7], [8].

• It plays the central role in refined topological strings [9], where the central object of the formalism — refined topological vertex — can be identified with the intertwining operator of Fock representations of DIM algebra [3]. See Eq. (1) for an illustration of such a vertex/intertwiner. It also endows toric Calabi-Yau three-folds with an interesting integrable structure [10] and implies $(q, t)$-KZ difference equations for refined topological string amplitudes [12].

• DIM algebra provides a universal way to understand “non-perturbative Ward identities”, or qq-characters [13], [14], [15], [16] for 4d, 5d and 6d quiver gauge theories. Composing the trivalent intertwiners of Fock representations of DIM algebra according to a toric diagram of a CY threefold, one can build a “two-dimensional” (or network) matrix model, which is related to a family of Dotsenko-Fateev-like integrable ensembles and the corresponding q-deformed vertex operator algebras [17].

1The construction also works for $\mathfrak{g} = \widehat{\mathfrak{g}}_n$. 

arXiv:1812.11961v3 [hep-th] 11 May 2021
• Very recently it was identified as the cohomological Hall algebra associated to CY three-folds [18].
• Higgsing construction can be employed to get holomorphic blocks [19] of 3d $\mathcal{N} = 2^*$ gauge theories from a specifically tuned network of intertwiners of DIM algebra [20].

In the current paper we focus on the last item in the above list (however, as we will see there are further ramifications) and introduce a convenient formalism for describing 3d $\mathcal{N} = 2^*$ quiver gauge theories.

Let us first recall the Higgsing construction (for details see [20]). The 3d theories can be understood as worldvolume theories on the vortices in the Higgs phase of 5d $\mathcal{N} = 1$ gauge theories [21]. In the $\Omega$-background there is an analogue of geometric transition [22], which relates the theory with $M$ vortices in the Higgs phase to the theory without vortices in the Coulomb phase with scalar field vev $a = \epsilon_2 M$. The geometric transition interpretation arises when we consider the Type IIB brane construction of the 5d gauge theory. $M$ vortices on the Higgs branch correspond to $M$ D3 branes stretching between NS5 and D5' branes, while the dual side (after the transition) corresponds to the resolution of the NS5 and D5' crossing. The five-brane picture, in turn is related to the combination of DIM intertwiners, as shown in [3]. This combination gives the partition function of the Higgsed 5d theory, and thus of the 3d theory.

Our new formalism bypasses the complicated Higgsing procedure. The major source of complications in the Higgsing approach is the need to construct an auxiliary 5d $\mathcal{N} = 1$ gauge theory, then tune its parameters to specific values, so that it reproduces the 3d theory on the worldvolume of the vortex defects appearing in the Higgs branch of the 5d theory.

Our new formalism, which we call the Higgsed network calculus, avoids the intermediate step (the auxiliary 5d theory) and allows for direct computation of the holomorphic blocks of the 3d theories. The formalism employs a "Higgsed" vertex which resembles refined topological vertex, but, unlike the latter, doesn’t introduce a bend in the five-brane. An example of two descriptions of the same 3d theory using the old and the new formalism is shown in Fig. 1. Overall, the Higgsed network looks as a collection of D3 branes (dashed lines in Fig. 1) stretched between a stack of parallel five-branes (solid lines).

![Figure 1: Comparison of two different formalisms for building a 3d $\mathcal{N} = 2^*$ quiver gauge theory. a) The old formalism: horizontal and vertical solid lines denote horizontal and vertical Fock representations respectively; circles and crossings denote resolved conifold-like geometries with specially tuned parameters. The notation is explained in detail in [20]. b) The new formalism. Solid horizontal lines still denote horizontal Fock spaces, while vertical dashed lines are vertical vector representations. They are joined together by Higgsed vertices. Notice how each circle in a) gives rise to dashed line emanating upwards from the corresponding point in b). Individual dashed lines correspond to screening charges acting on the Fock spaces represented by solid lines, so that the overall picture gives a Dotsenko-Fateev-like integral representation of the holomorphic block. c) The quiver gauge theory modelled by a) and b).](image)

On the algebraic side, Higgsed vertices can be thought of as elementary building blocks of screening currents, which commute with the action of a certain $W$-algebra and in this way can be used to define this algebra [23] [24]. It also turns out that in our approach we can easily reproduce the well-known result [25].

---

2By this we denote $\mathcal{N} = 4$ gauge theories with supersymmetry softly broken by a real axial mass. For the details see [20].
— that the holomorphic blocks of 3d gauge theories of the kind we are considering are eigenfunctions (or, more generally, kernel functions) of trigonometric Ruijsenaars-Schneider Hamiltonians.

Having thus reproduced the results of the old approach, we continue to some generalizations which are natural in the new formalism. We consider all three possible species of horizontal Fock representations and all three possible species of vertical vector representations and heavily employ the $S_3$ symmetry of the DIM algebra to build a network incorporating all of them (see Appendix A for details on the representations of DIM algebra). This corresponds to introducing several sorts of screening currents. The resulting model was considered in [24], and corresponds to a $W$-algebra associated with a superalgebra. We have thus obtained partition functions of 3d quiver theories corresponding to Dynkin diagrams of superalgebras. These theories should be 3d uplifts of 2d theories recently studied in [27] (see also earlier work [28]). We also prove that their partition functions are eigenfunctions of the supersymmetric Ruijsenaars-Schneider Hamiltonians [30].

The rest of the paper is structured as follows. In sec. 2 we present the systematic introduction of our formalism and examples of the computations reproducing the old construction: we write down one species of Higgsed vertices, show how to compose them into screening currents and derive the commutation relations for them. In sec. 3 we introduce the complete toolbox of vertices, build the fermionic screening current and write down the corresponding partition functions. We prove that the network partition functions are eigenfunctions of the supersymmetric Ruijsenaars-Schneider Hamiltonians in sec. 4. We present our conclusions and comment on future directions in sec. 5.

2 Intertwiners and blocks

In this section we introduce the Higgsed vertices $\Phi$ and $\Phi^*$, from which we build the “Higgsed network”. The vacuum matrix element of the network will give the partition function (holomorphic block) of the 3d quiver gauge theory.

We have collected the definitions of the DIM algebra and its relevant representations in the Appendix A not to clutter the presentation with too many technical details. However, the reader who is not familiar with DIM formalism is invited to consult it before proceeding to the main part of the text.

As a warm-up, let us recall the construction of the conventional refined topological vertices as intertwining operators of DIM algebra, proposed in [3]. In this approach five-branes of Type IIB string theory (or, equivalently, the edges of the toric diagram of a CY threefold) are identified with Fock representations $F_{(m,n)}q^{-1}$ of DIM algebra (see sec. A.3 for the definition of a Fock representation). The central charge vector of the Fock representation corresponds to the type of the fivebrane with (depending on an irrelevant choice of $SL(2,\mathbb{Z})$ duality frame) $(1,0)$ meaning NS5 and $(0,1)$ meaning D5'. The intertwiner of Fock representation is a trivalent junction of branes, as shown below:

Since the charges of the representations, or branes are conserved, the branes are bend at the junction. The basis in a Fock space is labelled by Young diagrams. Therefore, solid lines in Eq. (1) each carry a Young diagram, and gluing of two legs is performed by summing over a complete basis of states in the Fock space, i.e. over all Young diagrams. The result is just a network of intertwining operators, composed according to a five-brane web (or toric diagram of a CY). The vacuum matrix element of the network of intertwiners is equal to the refined topological string partition function on the toric CY [15] (see also ).

2.1 The intertwiners $\Phi$ and $\Phi^*$

Let us introduce the main character of our story, the Higgsed vertex, or the vector intertwiner $\Phi(w) : F_{(0,1)}q^{-1} \otimes \mathcal{V}_w \to F_{(1,0)}q^{-1}$, which we draw as

$$\Phi(w) = \begin{array}{c} \mathcal{V}_w \downarrow \mathcal{V}_w \\ F_{(1,0)}q^{-1} \end{array}$$
From now on all the Fock representations we will encounter will have the “direction” of the central charge equal to \((1, 0)\), and we omit it from our notation. The dashed vertical lines denote the vertical vector representations (see sec. A.1), while solid horizontal lines are still horizontal Fock representations (see sec. A.3), the latter exactly the same as in the ordinary DIM networks.

The vector representation has zero central charges, so when it joins a Fock representation the five-brane (which plays the role of the position of the five-brane) is not bent. This behavior reminds one of a D3 brane ending on an NS5 brane. In a moment we will see that this is not a coincidence and derive a precise relation between a network of intertwiners and the partition function of the effective 3d theory obtained from the D3 branes stretched between a stack of five-branes.

The intertwining property of \(\Phi\) means that \(\Phi \Delta(g) = g \Phi\) for any element \(g\) of DIM algebra (see the definition of the coproduct in sec. A.2). One can check that the following explicit expression\(^3\) for the intertwiner \([2]\) indeed satisfies this constraint:

\[
\Phi(w) = e^{-c_2 Q \frac{w^2}{w^*}} \exp \left[ -\sum_{n \geq 1} \frac{w^n}{n} \left( 1 - \frac{t^{-n}}{q^n} a_n \right) \right] \exp \left[ \sum_{n \geq 1} \frac{w^{-n}}{n} \left( 1 - \frac{t^n}{q^{-n}} a_n \right) \right]
\]

(3)

where we define \(q = e^{c_1}, t = e^{\beta c_1} = e^{-c_2}\) and the definition of the Fock space operators \(a_n\), \(P\) and \(Q\) are given in Eqs. (64), (65) in the Appendix A. Notice that though the Fock space is not bent (its slope is horizontal all the way through the intertwiner), as we see from Eq. (2) and the explicit expression (3), its spectral parameter (which plays the role of the position of the five-brane) is shifted after it passes the junction with the incoming dashed line.

We are already able to study the simplest nontrivial example, a network of two intertwiners:

\[
\mathcal{F}^{q, t^{-1}}_{t^2 u} \ni \langle \emptyset | \quad \begin{array}{c}
\begin{array}{c}
w_1 \\
o \\
w_2 \\
o \\
w_3 \\
o \\
\end{array}
\end{array} \quad | \emptyset \rangle \in \mathcal{F}^{q, t^{-1}}_u
\]

(4)

The corresponding expression is the matrix element of the product of two operators (3), which is evaluated by normal ordering the free fields:

\[
\langle \emptyset | t^2 u, \emptyset | \Phi(w_1) \Phi(w_2) | u, \emptyset \rangle = w_1^{\log_q u + \beta} w_2^{\log_q u} \exp \left[ -\sum_{n \geq 1} \frac{1}{n} \left( \frac{w_2}{w_1} \right)^n \left( 1 - \frac{t^{-n}}{q^n} a_n \right) \right] =
\]

\[
= w_1^{\log_q u + \beta} w_2^{\log_q u} \left( \frac{q^{w_1}; q}{w_1^{w_2}; q} \right)_\infty \left( q^{w_2}; q \right)_\infty
\]

(5)

Moving one step further, we get an answer for the network of \(n\) operators \(\Phi\) glued together horizontally:

\[
\mathcal{F}^{q, t^{-1}}_{t^n u} \ni \langle \emptyset | \quad \begin{array}{c}
\begin{array}{c}
w_1 \\
o \\
w_2 \\
o \\
w_3 \\
o \\
\end{array}
\end{array} \quad | \emptyset \rangle = A(w) \left( \prod_{i=1}^n w_i^{\log_q u + \beta(i-1)} \right) \prod_{i<j} \left( \frac{w_i}{w_j}; q \right)_\infty \left( \frac{w_j}{w_i}; q \right)_\infty
\]

(6)

where we extract the \(q\)-periodic prefactor

\[
A(w) = \prod_{i<j} \left( \frac{w_i}{w_j} \right)^{\beta} \theta_q \left( \frac{w_i}{w_j} \right) \theta_q \left( \frac{w_j}{w_i} \right)
\]

(7)

from the matrix element; here \(\theta_q(x) = (q; q)_\infty \frac{x; q}_\infty \frac{1;x q^{1/2}}{q^{1/2}}\) is Jacobi theta-function. We will see in what follows that such \(q\)-periodic factors will be mostly immaterial to the structure of the network. In particular, they factor out of the sums when we glue vector states together, and give an overall \(q\)-periodic prefactor for the network.

\(^3\)We rescale the coordinate \(w\) by \(q^{-\frac{2}{3}}\) compared to [29].
To build networks of intertwiners similar to (but simpler than) those considered in [3, 15, 16] we need one more operator, the dual intertwiner $\Phi^*(y): F_{u/t}^{(1,0)} \rightarrow F_{u/t}^{(1,0)} \otimes V_y^*$, which satisfies $\Delta(g)\Phi^* = \Phi^*g$.

An explicit check shows that the operator

$$F_{u/t}^{q,t-1} \rightarrow F_{u/t}^{q,t-1}$$

$$\downarrow \quad \downarrow$$

$$\forall y \quad F_{u/t}^{q,t-1}$$

$satisfies the intertwining property. Notice how the spectral parameter of the Fock space to the left of the dual intertwiner $\Phi^*$ is shifted the opposite way, compared to the intertwiner $\Phi$.

The matrix elements of products of $\Phi^*$ are given by

$$\begin{align*}
\langle \varnothing | F_{u/t}^{q,t-1} | \varnothing \rangle &= \left( \prod_{i=1}^{n} y_i^{-\log_q u + \beta(n-i+1)} \right) \prod_{i<j} \left( \prod_{k<l} y_i y_j \right)^{\log_q n} \prod_{a=1}^{m} \frac{y_{a}}{t^{2} y_{a}} \frac{q}{y_{a}}^{\beta} \\
\langle \varnothing | F_{u/t}^{q,t-1} | \varnothing \rangle &= \left( \prod_{i=1}^{n} y_i^{-\log_q u + \beta(n-i+1)} \right) \prod_{i<j} \left( \prod_{k<l} y_i y_j \right)^{\log_q n} \prod_{a=1}^{m} \frac{y_{a}}{t^{2} y_{a}} \frac{q}{y_{a}}^{\beta} \\
\end{align*}$$

Combining $\Phi$ and $\Phi^*$ we get

$$\begin{align*}
\langle \varnothing | F_{u/t}^{q,t-1} | \varnothing \rangle &= A(\bar{u}, \bar{y}) B(\bar{u}, \bar{y}) \\
\langle \varnothing | F_{u/t}^{q,t-1} | \varnothing \rangle &= A(\bar{u}, \bar{y}) B(\bar{u}, \bar{y}) \\
\end{align*}$$

where an additional $q$-periodic prefactor reads

$$B(\bar{u}, \bar{y}) = \prod_{a=1}^{m} \prod_{b=1}^{n} \left[ \frac{y_{a}^{b} \theta_{q}^{\beta} \left( \frac{t^{2} y_{a}}{\mu_{a}} \right)}{\theta_{q}^{\beta} \left( \frac{t^{2} y_{a}}{\mu_{a}} \right)} \right].$$

We can already notice that the $q$-Pochhammer factors in Eq. [10] resemble those of the holomorphic block integrand for a pair of $\mathcal{N} = 2$ bifundamental chiral multiplets charged under $U(n) \times U(n)$ flavour symmetry. In this case the parameter $q$ is identified with the parameter of the 3d $\Omega$-background $S^2 \times D_2$ and $t$ is related to the real axial mass deformation of the $\mathcal{N} = 4$ theory. Together the two chirals constitute what we might call a bifundamental $\mathcal{N} = 2^*$ multiplet, i.e. what remains of the $\mathcal{N} = 4$ bifundamental multiplet after turning on the $t$-parameters responsible for the soft breaking of supersymmetry. Indeed, if we set the masses associated to $U(n)$ flavours to $\mu_{i} = y_{i}$, $i = 1, \ldots, n$ and the $U(m)$ masses to $\bar{\mu}_{j} = \sqrt{t} w_{j}$, $j = 1, \ldots, m$, we find that we reproduce the bifundamental contribution

$$\prod_{a=1}^{m} \prod_{b=1}^{n} \left[ \frac{t^{2} \mu_{a}^{b} \theta_{q}^{\beta} \left( \frac{t^{2} \mu_{a}}{\mu_{b}} \right)}{\theta_{q}^{\beta} \left( \frac{t^{2} \mu_{a}}{\mu_{b}} \right)} \right].$$

To the $D_2 \times S^1$ partition function. Thus, $n$ dashed lines coming from the top of the picture in Eq. [10] correspond to a $U(n)$ flavour group and $m$ dashed lines escaping from the bottom are related to $U(m)$.
flavour group. Thus, our initial guess that the dashed lines are somehow associated with D3 branes seems to be plausible: the 3d bifundamental chirals couple the $U(n)$ and $U(m)$ gauge theories living on the stacks of D3 branes. The D3 branes are semi-infinite, so the gauge fields are frozen and the gauge symmetries become flavour symmetries of the 3d theory of bifundamental chirals.

What is the field theory role of the remaining factors in Eq. (10)? First of all, the $q$-periodic contributions in the holomorphic blocks are not important, since they cancel when one combines two blocks into a partition function for a compact manifold (e.g. $S^3_b$). Additional $q$-Pochhammers in Eq. (10) can be thought of as coming from flipping fields [20], charged under flavour symmetries $U(n)$ and $U(m)$.

We will see in what follows that when we glue pictures like (10) along the dashed lines we effectively gauge the corresponding flavour groups. The flipping fields coming from both sides then combine into an $\mathcal{N}=2$ vector and adjoint chiral contribution for the gauged symmetry. This is in accordance with the D3 brane interpretation: the couplings on the branes are unfrozen, when the branes have finite length.

2.2 Commutation relations for the intertwiners

For the moment we have only shown how to compose the intertwiners $\Phi$ and $\Phi^*$ horizontally. However, we can already make a natural and meaningful exercise with our building blocks. Let us compare different orderings of the intertwiners along the solid line. There are three possibilities:

1. Commutation of $\Phi$ with $\Phi$: 

$$w_1 \quad w_2 \quad = \left[ \frac{w_1}{w_2} \right]^\beta \theta_q \left( \frac{t \left( \frac{w_1}{w_2} \right)}{\theta_q \left( w_2/w_1 \right)} \right) R \left( \frac{w_1}{w_2} \right) \times w_2 \quad w_1$$

where

$$R(x) = \frac{(x; q)_\infty (qx; q)_\infty}{(tx; q)_\infty (tqx; q)_\infty}. \quad (14)$$

The terms in the square brackets in Eq. (13) combine into a $q$-periodic function of $w_{1,2}$, which, as we have mentioned above, is not important for our network construction. The function $R(x)$ is the “miniature version” of the DIM $R$-matrix [10], [32]. In our case the $R$-matrix permutes two vector representations living on the vertical dashed lines.

2. Commutation of $\Phi^*$ with $\Phi^*$. For the dual intertwiners we find

$$y_1 \quad y_2 \quad = \left[ \frac{y_1}{y_2} \right]^\beta \theta_q \left( \frac{y_2}{y_1} \right) \frac{1}{R \left( \frac{y_1}{y_2} \right)} \times y_2 \quad y_1$$

which features an inverse of the $R$-matrix from Eq. (13) together with another $q$-periodic factor.

3. Commutation of $\Phi$ with $\Phi^*$. Finally, we have

$$w_1 \quad y_2 \quad = \left[ \frac{y_2}{w_1} \right]^\beta \theta_q \left( \sqrt{\frac{t \left( \frac{y_2}{w_1} \right)}{\theta_q \left( \frac{w_1}{y_2} \right)}} \right) \times w_1 \quad y_2$$

We find that $\Phi$ and $\Phi^*$ commute, up to $q$-periodic factors, which for us is as good as commutativity.

2.3 Vertical gluing and $q$-Virasoro screening charges

We pass to the next necessary step in building the network of intertwiners — vertical gluing. In our convention the states in the vector representation correspond to the shifts of the spectral parameter $w \mapsto q^k w$. Thus, to sum over the complete basis of states in the vector representation we need to
take the sum over $k$, or, equivalently, the so-called Jackson $q$-integral over the spectral parameter $w$ of the vector representation. For example, gluing together two dual intertwiners we get an operator $Q^{q,t^{-1}}_q : F^{q,t^{-1}}_{t^{-1}u_1} \otimes F^{q,t^{-1}}_{t^{-1}u_2} \rightarrow F^{q,t^{-1}}_{t^{-1}u_1} \otimes F^{q,t^{-1}}_{t^{-1}u_2}$:

$$Q^{q,t^{-1}}_q = \sum_{k \in \mathbb{Z}} \frac{\gamma^q_{q^k w}}{q^k w} F^{q,t^{-1}}_{t^{-1}u_1} \otimes F^{q,t^{-1}}_{t^{-1}u_2} = \sum_{k \in \mathbb{Z}} \Phi(q^k w) = \int_{-\infty}^{\infty} d_q w \otimes \Phi(w) = \int_{-\infty}^{\infty} d_q w S^{q,t^{-1}}_q(w) =$$

$$= \sum_{k \in \mathbb{Z}} e^{-c_2(Q_1 - Q_2)} (q^k w)^{\beta + 1} \frac{a_n^1}{q^n} \exp \left[ - \sum_{n \geq 1} \frac{w^n}{n} \sum_{n \geq 1} \frac{1}{1 - q^n} \left( a_{-n}^{(2)} - \left( \frac{t}{q} \right)^{\frac{q}{2}} a_{-n}^{(1)} \right) \right] \times \exp \left[ \sum_{n \geq 1} \frac{w^{-n}}{n} \sum_{n \geq 1} \frac{1 - t^n}{1 - q^{-n}} \left( a_{n}^{(2)} - \left( \frac{t}{q} \right)^{\frac{q}{2}} a_{n}^{(1)} \right) \right], \quad (17)$$

where we denote by $a_n^{(1)}$ (resp. $a_n^{(2)}$) creation and annihilation operators acting on the upper (resp. lower) horizontal Fock space (similarly for the zero modes $P_{1,2}$ and $Q_{1,2}$). One more convenient representation of the vertical gluing is the contour integral over an appropriate contour in the complex $w$ plane. One way to rewrite Eq. (17) as a contour integral is to notice that

$$\frac{(q;q)_\infty^2}{(a;q)_\infty (\frac{a}{q};q)_\infty} \oint_C d\xi \frac{\log a}{\theta_q \left( \frac{\xi}{w} \right)} f(\xi) = \sum_{k \in \mathbb{Z}} f(q^k w), \quad (18)$$

for almost any $a \in \mathbb{C}$, where $C$ wraps the poles of the theta-function in the denominator. Therefore, by inserting the theta-functions and a prefactor, as in Eq. (18), under the integral and integrating over a specific contour we can turn the integral into a sum. It turns out that for certain combinations of intertwiners the contour $C$ can be traded for other contours wrapping poles of the correlation functions (10).

As have been noted in e.g. [31][32], eventually all the representations of the “trigonometric integrals” — either as a sum, or as a Jackson $q$-integral, or as a contour integral — boil down to the same expression and are completely equivalent. Similar equivalence occurs in the Dotsenko-Fateev representations of $q$-deformed conformal blocks and in the holomorphic blocks of 3d theories. We will mostly use the contour integral representation, usually assuming that the contour wraps the poles of the correlation functions under the integral.

In fact, the integrand $S^{q,t^{-1}}_q(w)$ in the first line of Eq. (17) is nothing but the screening current of the $q$-Virasoro algebra $Vir_{q,t}$, built from the pair of free bosons $a_n^{(1,2)}$ [15]. Thus $Q^{q,t^{-1}}_q$ is the screening charge, commuting with the action of $Vir_{q,t}$. As explained in [21][15] this algebra is a subalgebra of the DIM algebra, i.e. one can build a current from a combination of DIM generators, so that when acting on the tensor product of two horizontal Fock representations it reproduces the relations of $Vir_{q,t}$. Since the network of intertwiners (17) commutes with $\Delta(g)$ for any $g$ from the DIM algebra, it also commutes with the $q$-Virasoro current. We can write the intertwining relation graphically:

$$\sum_{k \in \mathbb{Z}} \frac{\gamma^q_{q^k w}}{q^k w} \Delta(g) = \sum_{k \in \mathbb{Z}} \frac{\gamma^q_{q^k w}}{q^k w} \Delta(g) \quad (19)$$

where the double line denotes the position of the operator $\Delta(g)$ on the horizontal lines, or as a formula

$$[Q^{q,t^{-1}}_q, \Delta(g)] = 0. \quad (20)$$
A more general network can be obtained by adding external dashed lines, e.g.

\[
\sum_{k \in \mathbb{Z}} w^{k} w^{q, t-1}_{w_k} + \prod_{k \in \mathbb{Z}} F^{q, t-1}_{y_{k}} \nu_{1}^{q, t-1} u_{1}^{q, t-1} \nu_{2}^{q, t-1} u_{2}^{q, t-1}
\]

One can see that the external lines correspond to degenerate vertex operators of the \(\text{Vir}_{q,t}\) algebra, similarly to [15]. The network (21) is therefore a product of screened degenerate vertex operators. Taking the vacuum matrix element of Eq. (21) we get

\[
\langle \emptyset | (21) \otimes \emptyset \rangle = A(w_1, w_2) B(w_1, w_2, y) \left( \prod_{i=1}^{2} \frac{\log \frac{w_i}{w_i} + \beta (i-3)}{w_i} \right) \times \\
\times \frac{\left( \frac{w_1}{w_2} ; q \right)_\infty \left( \frac{w_2}{w_1} ; q \right)_\infty}{\left( \frac{y_1}{y_2} ; q \right)_\infty} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \frac{\left( t \sqrt{\frac{y_1}{y_2}} \right)_w \left( q \right)_2}{\left( \sqrt{\frac{y_1}{y_2}} ; q \right)_\infty} \frac{\left( \frac{w_1}{w_2} ; q \right)_\infty \left( \frac{w_2}{w_1} ; q \right)_\infty}{\left( \frac{y_1}{y_2} ; q \right)_\infty} \left( \frac{t \sqrt{\frac{y_1}{y_2}} , q \right)}{(22)}
\]

where \(A(w)\) and \(B(w, \tilde{y})\) are periodic factors from Eq. (7) and from Eq. (11) respectively.

The 3d gauge theory corresponding to the network (21) can be deduced either from the form of the integrand (22) \((q\)-Pochhammer ratios give two pairs of chiral operators and a single integration implies a \(U(1)\) gauge group) or directly by interpreting (21) as a brane picture (the intermediate dashed line gives the \(U(1)\) gauge theory and two upper dashed lines contribute two fundamental multiplets, i.e. two pairs of fundamental chiral fields). In any case, the resulting theory is the \(\mathcal{N} = 2^*\) version of the \(T[SU(2)]\) theory. The masses of the fundamental multiplets are \(\mu_i = \sqrt{w_i}\), and the FI parameter of the \(U(1)\) gauge group is \(\tau = \frac{\mu_2}{\mu_1}\). The prefactor in the second line of Eq. (22) corresponds to flipping fields of the \(U(2)\) flavour symmetry group.

Let us make a comment about the contours, over which one can integrate the screening currents. If we consider the space of intertwining operators of the form (21) as a vector space over \(q\)-periodic functions of the parameters, it turns out to be two dimensional. One can obtain this fact using several different lines of arguments:

1. As we show in sec. 4 the network (21) is an eigenfunctions of the Ruijsenaars difference operator with the eigenvalue independent of \(y\). \(q\)-periodic functions pass through the difference operator, so one can study the space of eigenfunctions as a vector space over the field of \(q\)-periodic functions in the same way as one studies the space of eigenfunctions of a differential operator over the field of constants. The difference operator is of second order, therefore the space of solutions is two-dimensional.

2. The 3d theory \(T[SU(2)]\) corresponding to the network has two vacua. These vacua correspond to two linearly independent networks of intertwiners.

We can write two linearly independent networks of intertwiners similarly to (22), but with the Jackson \(q\)-integrals replaced by the contour integrals over the contours \(C_{1,0}\) and \(C_{0,1}\), wrapping the poles at \(y = \sqrt{\frac{w_i}{w_1}} q^k\), \(k \in \mathbb{Z}_{\geq 0}\) and \(y = \sqrt{\frac{w_2}{w_1}} q^k\), \(k \in \mathbb{Z}_{> 0}\) respectively. One can also isolate the contributions of contours \(C_{1,0}\) and \(C_{0,1}\) by taking the residue in the \(y\)-parameter of the intermediate dashed line at \(y = \sqrt{\frac{w_i}{w_1}}\).

In what follows, not to overburden the notation, we will omit writing the sums and the shifts of the intermediate dashed lines on our diagrams. In this convention two networks corresponding to contours...
$C_{1,0}$ and $C_{0,1}$ are given by the following pictures

\[
\begin{align*}
\mathcal{F}_{q,t^{-1}}^{w_1} & \quad \mathcal{F}_{q,t^{-1}}^{w_2} \\
\sqrt{T} w_1 & \quad \sqrt{T} w_2
\end{align*}
\]

Notice how the lower dashed lines “cling” to the upper dashed lines. As we have explained, this is the consequence of the structure of poles of the integrand. For several screenings stretched between two neighbouring horizontal lines (i.e. for a non-abelian $3d$ theory), from the first look at the structure of the integrand one could have assumed that the intermediate lines can also “cling” together forming stacks of branes. Indeed, the interaction between two parallel branes gives a denominator $(t \frac{w_i}{y_i}; q)_\infty$. For example, the picture:

\[
\begin{align*}
\mathcal{F}_{q,t^{-1}}^{w_1} & \quad \mathcal{F}_{q,t^{-1}}^{w_2} \\
\sqrt{T} w_1 & \quad \sqrt{T} w_2
\end{align*}
\]

corresponds to the integral

\[
\int_{C} \frac{d^2 y}{(y_1 y_2)^{2 \beta}} \log_y \left( \frac{w}{y_1 y_2} \right)^{2 \beta} \prod_{k \neq l} \left( \frac{y_k}{y_l} ; q \right)_\infty \prod_{j=1}^2 \left( \frac{t \sqrt{T} y_j}{y_j} ; q \right)_\infty.
\]

The “stacking” of branes would have corresponded to the contour of double integration $C = C_{0,2}$ over the spectral parameters $y_1$ and $y_2$, which wraps the poles $y_1 = \sqrt{T} w_2 q^{k_1}$, $y_2 = \sqrt{T} w_2 q^{k_2}; t^{-1}$, with $k_1, k_2 \in \mathbb{Z}_{>0}$. However, in fact this group of poles gets cancelled by the numerators $(t \sqrt{T} y_j ; q)_\infty$ in the integrand. Therefore parallel dashed lines between the same horizontal lines cannot cling together and always cling to separate upper dashed lines.

As one can deduce from the brane diagram, the $3d$ theory corresponding to the network (24) is the $U(2)$ gauge theory (two intermediate dashed lines) with two fundamental multiplets (two external dashed lines). It has only one arrangement of branes in which $y_{1,2} = \sqrt{T} w_1, 2q^{k_1,2}$. Thus, the resulting theory has only one vacuum. Geometrically, this theory corresponds to counting certain quasimaps to the target $\text{Gr}(2,2) \simeq \text{Gr}(0,2)$, i.e. to a point.

In general, the network with two horizontal lines corresponds to a $3d$ with a single gauge group $U(m)$ and a number $n$ of fundamental multiplets:

\[
\begin{align*}
\mathcal{F}_{q,t^{-1}}^{w_1} & \quad \mathcal{F}_{q,t^{-1}}^{w_n} \\
y_1 & \quad y_m
\end{align*}
\]

There are $\frac{n!}{m!(n-m)!}$ vacua, corresponding to the contours of integration $C_{1,0, \ldots, 1}$ with $m$ ones and $(n-m)$ zeroes. Graphically this number is explained as follows: $m$ intermediate dashed lines can cling to separate external dashed line, and all the intermediate dashed lines are identical, hence $m!$ in the denominator. These vacua are identified with fixed points of $(\mathbb{C}^*)^n$ action on $\text{Gr}(m,n)$ (notice that we consider only
The corresponding integrals are given by

$$\langle \varnothing | \varnothing \rangle \sim \prod_{k<l} \frac{\langle w_k w_l \rangle_q}{\langle t w_k w_l \rangle_q} \prod_{i=1}^m \int d^m y \prod_{i=1}^m y_i \log_{\frac{q}{q_2^L}} \frac{\Delta_{q,t}^{(n)}(\vec{y})}{\Delta_{m,n}^{(q,t)}(\vec{y}, \vec{w})},$$

where

$$\Delta_{n,m}^{(q,t)}(\vec{y}) = \prod_{k \neq l} \frac{\langle w_k w_l \rangle_q}{\langle t w_k w_l \rangle_q}, \quad \Delta_{m,n}^{(q,t)}(\vec{y}, \vec{w}) = \prod_{i=1}^m \prod_{j=1}^n \frac{\langle \sqrt{\frac{q}{q_2^L}} w_i \rangle_q}{\langle \sqrt{\frac{t}{t \cdot t_1}} w_i \rangle_q}. \quad (27)$$

This is precisely the integral for the holomorphic block of the $U(m)$ theory with $n$ fundamental multiplets. The prefactors again play the role of flipping fields of the flavour symmetry. We can relate the parameters of the network to that of the gauge theory on $S^1 \times \mathbb{R}^2$. We write down the dictionary in Tab. 1.

| $3d\ U(m)$ gauge theory | Higgsed network $[21]$ |
|--------------------------|-------------------------|
| Axial real mass $m_A$    | $\frac{1}{\lambda_{u_1}} \ln \left( -\frac{\sqrt{q}}{\lambda} \right)$ |
| 3d $\Omega$-background parameter | $q$ |
| FI parameter $\tau$     | $\frac{u_k}{u_1}$ |
| Flavour masses $\mu_i$  | $\sqrt{\frac{t}{t \cdot t_1}} w_i$ |
| Vacua                    | Contours of integration |

Table 1: Dictionary between the parameters of the 3d gauge theory and Higgsed network.

### 2.4 $qW_N$-algebra screenings and 3d quivers

We can stack more than two horizontal Fock representations on top of each other and stretch vector representations between them. For example:

\[
\begin{array}{c}
\mathcal{F}_{q,t}^{u_1} \\
\mathcal{F}_{q,t}^{u_2} \\
\mathcal{F}_{q,t}^{u_3}
\end{array}
\]

\[
\begin{array}{ccc}
\cdots \cdots \cdots \\
\mathcal{F}_{q,t}^{u_1} \\
\mathcal{F}_{q,t}^{u_2} \\
\mathcal{F}_{q,t}^{u_3}
\end{array}
\]

\[
\begin{array}{cccc}
\cdots \cdots \cdots \\
\mathcal{F}_{q,t}^{u_1} \\
\mathcal{F}_{q,t}^{u_2} \\
\mathcal{F}_{q,t}^{u_3}
\end{array}
\]

The intermediate dashed lines can now stretch between either the upper two Fock spaces or the lower two. This gives rise to two screening currents, $S_{q,12}^{q,t^{-1}}(y)$ and $S_{q,23}^{q,t^{-1}}(z)$ (and the corresponding screening charges), which are similar to the Virasoro one [17] with appropriate change of $a_n^{(1,2)}$ to $a_n^{(2,3)}$ in $S_{q,23}^{q,t^{-1}}(z)$. The algebra commuting with the screening charges is the $q$-deformed $W_3$-algebra. The commutation can be inferred from the DIM intertwining relations exactly as in Eq. [19].

Two sorts of screening currents have nontrivial normal ordering, because the bosonic operators $a_n^{(2)}$ are shared between them. In fact the normal ordering produces the interaction, dictated by the $A_2$ Cartan matrix, between the integration variables $y_i$ and $z_j$. Thus, the vacuum matrix element of the network [20].
is the $A_2$-type $q$-conformal matrix model, as in [8]:

\[
\langle \emptyset | \prod_{k<l} \left( \frac{w_k}{w_l} : q \right) \phi_{k,l}^{(q)} \prod_{i=1}^{m} \left( \frac{y_i}{\bar{y}_i} : q \right) \phi_{y_i,\bar{y}_i}^{(q)} \prod_{i=1}^{k} \left( \frac{k}{\bar{k}} : q \right) \phi_{k,\bar{k}}^{(q)} \prod_{i=1}^{n} \left( \frac{\mu_i}{\bar{\mu}_i} : q \right) \phi_{\mu_i,\bar{\mu}_i}^{(q)} \rangle = \int_{\mathcal{C}_1 \ldots \mathcal{C}_n} d^m y \int_{\mathcal{C}_1 \ldots \mathcal{C}_n} d^k z \prod_{i=1}^{m} y_i^{-2 \beta - 1} \prod_{i=1}^{k} z_i^{-2 \beta - 1} \frac{\Delta_k^{(q,t)}(z) \Delta_{\bar{k},m}^{(q,t)}(\bar{y})}{\Delta_{k,m}^{(q,t)}(z, \bar{y})},
\]

where $\Delta$ and $\bar{\Delta}$ are given in Eq. (28). The corresponding gauge theory is a linear quiver

\[
U(k) \rightarrow U(m) \rightarrow \cdots \rightarrow U(n)
\]

(31)

For $N$ horizontal lines there will be $(N-1)$ intermediate stacks of D3 branes and correspondingly, the 3d quiver would have $(N-1)$ nodes, since each D3 stack corresponds to a gauge group.

## 3 Bosonic and fermionic screenings

In this section we follow the natural development of our formalism and introduce additional intertwiners, which are obtained by acting with the $\mathfrak{S}_3$ permutation symmetry of DIM on $\Phi$ and $\Phi^*$. When combined into a network, these new intertwiners produce new screening currents and charges, defining more general $W$-algebras and 3d quiver gauge theories, which both turn out to be associated with super algebras. In this way we reproduce the results of [24] on $W$-algebras associated to DIM algebra in a simplified and streamlined way.

### 3.1 Dual screenings

As shown in sec. A.3, the Fock space representation $\mathcal{F}_u^{q,t-1}$ of DIM is invariant under the symmetry $q \leftrightarrow t$. However, the intertwining operators, $\Phi$ and $\Phi^*$ from Eqs. (3) and (8) respectively are not invariant. This is not a surprise of course, since the operators $\Phi$ and $\Phi^*$ intertwine tensor products of $\mathcal{F}_u^{q,t-1}$ with $V_q$ and while the former is invariant under $q \leftrightarrow t$, the latter is not. Acting with the symmetry $q \leftrightarrow t$ on $\Phi$ and $\Phi^*$ we obtain new intertwiners. At this point we need to refine our notation slightly in order not to confuse different operators. We call the intertwiners $\Phi$ and $\Phi^*$ from Eqs. (3) and (8) $\Phi_{q,t-1}^q(w)$ and $\Phi_{q,t-1}^{q*}(w)$ with the indices signifying the spaces they act on. We also introduce the color-coded graphical notation with three vector representations $V_q^w$, $V_t^{-1}$ and $V_{t/q}^w$ drawn as blue, red and violet dashed lines respectively. In this way each parameter $(q,t^{-1},t/q)$ corresponds to a color: $q$ to blue, $t^{-1}$ to red, $t/q$ to violet. The Fock spaces also carry the color corresponding to their “missing index”: $\mathcal{F}_u^{q,t-1}$ is violet, $\mathcal{F}_u^{q,t/q}$ is red, $\mathcal{F}_u^{q,t^{-1}/t}$ is blue. The intertwiners $\Phi_{q,t-1}^q(w)$ and $\Phi_{q,t^{-1}}^{q*}(w)$ are then drawn as

\[
\Phi_{q,t-1}^q(w) = \Phi_{q,t-1}^{q*}(w)
\]

(32)

\[
\Phi_{q,t^{-1}}^{q*}(w) = \Phi_{q,t^{-1}}^q(w)
\]

(33)
The new intertwiners are drawn as

\[
\Phi_{q,t^{-1}}^{-1}(w) : F_{u}^{(1,0),q,t^{-1}} \otimes V_{w}^{t^{-1}} \rightarrow F_{q,t^{-1}}^{(1,0),q,t^{-1}}
\]

(34)

\[
\Phi_{q,t^{-1}}^{q,t^{-1}}(w) : F_{u}^{(1,0),q,t^{-1}} \otimes V_{w}^{t^{-1}} \rightarrow F_{q,t^{-1}}^{(1,0),q,t^{-1}}
\]

(35)

The explicit expressions for the new intertwiners are as follows:

\[
\Phi_{q,t^{-1}}^{-1}(w) = e^{-c_1q w^2 / 2} \exp \left[ - \sum_{n \geq 1} \frac{w^n}{n} a_{-n} \right] \exp \left[ \sum_{n \geq 1} \frac{w^{-n}}{n} a_{n} \right],
\]

(36)

\[
\Phi_{q,t^{-1}}^{q,t^{-1}}(w) = e^{c_1q y^2 / 2} \exp \left[ \sum_{n \geq 1} \frac{y^n}{n} \left( \frac{1}{q} \right)^{n/2} a_{-n} \right] \exp \left[ - \sum_{n \geq 1} \frac{y^{-n}}{n} \left( \frac{t}{q} \right)^{n/2} a_{n} \right],
\]

(37)

where we have applied the symmetry (70) to the intertwiners (3) and (8). Of course, all the results for normal ordering, commutation and gluing obtained in sec. 2 hold for the red dashed lines as well, provided one exchanges $q \leftrightarrow t^{-1}$ in all the expressions (hence, for example, the integrations over the spectral parameters of the intermediate red dashed lines are $t^{-1}$-periodic).

One can use the new intertwiners together with the “old” ones to obtain more general networks. The color rule for gluing the colored lines is simple: the intertwiners we have just described (Eqs. (32)-(35)) connect dashed lines and solid lines of colors which do not coincide. For example, a red dashed line can connect to blue and violet, but not red horizontal lines. Let us for the moment consider horizontal lines of only one color, say violet (the general setup will be described in sec. 3.2).

For the simplest example, consider two violet horizontal lines. We can stretch either blue or red dashed lines between them:

\[
\int_{-\infty}^{\infty} d_{t^{-1}} y_1 \int_{-\infty}^{\infty} d_{q} y_2 \Phi_{q,t^{-1}}^{q,t^{-1}}(y_1) \Phi_{q,t^{-1}}^{q,t^{-1}}(y_2) = \int_{-\infty}^{\infty} d_{t^{-1}} y_1 \int_{-\infty}^{\infty} d_{q} y_2 S_{q,t^{-1}}^{q,t^{-1}}(y_1) S_{q,t^{-1}}^{q,t^{-1}}(y_2).
\]

(38)

These two types of lines give rise to two types of screening currents $S_{q,t^{-1}}^{q,t^{-1}}(w)$ (“blue” current) and $S_{q,t^{-1}}^{q,t^{-1}}(w)$ (“red” current). Both of them commute with the action of DIM algebra, and therefore with the action of the $q$-Virasoro acting on the Fock spaces. In fact these two screenings also commute with each other and constitute the well-known standard set of screenings of the $q$-Virasoro algebra.

To give a more familiar example of the same situation consider the ordinary Virasoro algebra built from a free field $\phi(x)$ and generated by $T(z) = (\partial \phi(z))^2 + b^{-1} \partial^2 \phi(z)$. Then there are two standart screening currents: $e^{b\phi(x)}$ and $e^{b^{-1}\phi(x)}$; commuting with $T(z)$ related by the symmetry $b \leftrightarrow \frac{1}{b}$. This symmetry is exactly the symmetry $q \leftrightarrow t^{-1}$ of the $q$-deformed model.

As noted in [24], the red and blue screening currents commute:

\[
[S_{q,t^{-1}}^{q,t^{-1}}(w), S_{q,t^{-1}}^{q,t^{-1}}(y)] = 0.
\]

(39)

However, their normal ordering is nontrivial, though it doesn’t contain $q$-Pochhammer symbols as the ordering between screening currents of the same color:

\[
S_{q,t^{-1}}^{q,t^{-1}}(y_1) S_{q,t^{-1}}^{q,t^{-1}}(y_2) = \frac{y_1^2}{(1 - \frac{1}{2} \frac{y_1^2}{q}) (1 - \frac{1}{2} \frac{y_2^2}{q})} : S_{q,t^{-1}}^{q,t^{-1}}(y_1) S_{q,t^{-1}}^{q,t^{-1}}(y_2) :.
\]

(40)
Thus, the integrals corresponding to the networks with two violet horizontal lines can be described as a pair of coupled $q$-Dotenko-Fateev-type integral ensembles:

\[
\langle \emptyset | y_1 \cdots y_m | \emptyset \rangle \sim \oint_{\mathcal{C}_y} d^m y \prod_{i=1}^m y_i^{-\log \frac{n_+}{l_+} - \frac{\varphi}{2} - 1} \frac{\Delta_{m,n}^{(q^{-1}-q^{-1})}(y)}{\Delta_{m,n}^{(q^{-1}-q^{-1})}(y,w)} \prod_{i=1}^l z_i^{-\log \frac{m_+}{m_1} + 2\beta - 1} \frac{\Delta_{l,k}^{(q,t)}(z)}{\Delta_{l,k}^{(q,t)}(z,x)}
\]

The coupling between two DF integral (one with parameters $(q,t)$ and the other with $(t^{-1}, q^{-1})$) in the last line in Eq. (41) is due to the interaction (40).

From the field theory point of view the integral (41) describes two 3d theories:

1. $\mathcal{N} = 2^* U(m)$ gauge theory with $n$ fundamental multiplets in the $\Omega$-background with parameter $q$ and axial mass deformation $t$,

2. $\mathcal{N} = 2^* U(l)$ gauge theory with $k$ fundamental multiplets in the $\Omega$-background with parameter $t^{-1}$ and axial mass deformation $q^{-1}$.

These two theories are coupled through a 1d interaction term. This setup was described in [26]. All these screening charges commute with the action of $qW_N$ algebra. The corresponding field theory is a pair of 3d theories coupled thorough 1d interaction.

### 3.2 Gluing different Fock spaces. Fermionic screenings

The final logical step in our formalism is to stack together horizontal lines of different colors. Let us start with two lines, e.g. violet and red. Between them we can stretch dashed lines of the color different from each horizontal line. There is, therefore, only one choice, blue, which produces the screening current $S_q^a t^{-1}|q,t/q \langle w |$

\[
\langle \emptyset | y_1 \cdots y_m | \emptyset \rangle = \int_{-\infty}^{\infty} dy \Phi_q^{q,t/q}(y) \otimes \Phi_q^{a,t-1}(y) = \int_{-\infty}^{\infty} dy S_q^a t^{-1}|q,t/q \langle y |. \tag{42}
\]

Evaluating the screening current explicitly we get

\[
S_q^a t^{-1}|q,t/q \langle y | = e^{-c_1+c_2} Q_1 - c_2 Q_2 y^{(1+t)^{-1} - \frac{2}{t} R_2} \exp \left[ \sum_{n \geq 1} \frac{y^n}{n(1-q^n)} \left( t^{\frac{2}{t}} (1 - (t/q)^n) a_n^{(1)} - (1 - t^{-n}) a_n^{(2)} \right) \right] \times \exp \left[ \sum_{n \geq 1} \frac{y^{-n}}{n(1-q^n)} \left( t^{\frac{2}{t}} (1 - (q/t)^n) a_n^{(1)} + (1 - t^n) a_n^{(2)} \right) \right]. \tag{43}
\]

where the bosons satisfy

\[
[a_n^{(1)}, a_m^{(1)}] = n \frac{1 - q^{-1}}{1 - q^{-1}} \delta_{n+m,0}, \quad \quad [a_n^{(2)}, a_m^{(2)}] = n \frac{1 - q^{-1}}{1 - q^{-1}} \delta_{n+m,0}. \tag{44}
\]

An explicit calculation shows that the currents $S_q^a t^{-1}|q,t/q \langle y |$ anticommute. Such fermionic screenings appear naturally in the context of $W$-algebras associated with superalgebras [24]. In particular, on
two horizontal lines of different colors, DIM algebra is expected to act as a $W$-algebra associated to superalgebra $\mathfrak{gl}_{1|1}$ (somewhat similarly to the case of two Fock spaces of the same color where a product of $q$-Virasoro and Heisenberg algebras, associated to $\mathfrak{gl}_2$ acts). Having the fermionic screening we can build interesting DF-type integrals and the corresponding $3d$ quiver gauge theories. Both of them are associated to Dynkin diagrams of superalgebras. Let us write down the simplest example, corresponding to the network

$$
\begin{array}{c}
v_1 \quad \cdots \quad v_n \\
y_1 \quad \cdots \quad y_m \\
z_1 \quad \cdots \quad z_k \\
p_1 \quad \cdots \quad p_l \\
w_1 \quad \cdots \quad w_n \\
\end{array}
\quad \Leftrightarrow 
\begin{array}{c}
U(2) \quad 2 \\
\tau_1/\tau_2 \quad \mu_i \\
\end{array}
\quad (45)
$$

The vacuum matrix element of (45) is

$$
\oint_{C_{1,1}} (y_1 y_2)^{\log \tau_1 + 2\beta - 3} \frac{\Delta_2(\bar{y})}{\Delta_{2,2}^{(q,t/\tau)}(\bar{y}, \bar{v})},
\quad (46)
$$

where $\Delta_2(\bar{y})$ is the square of the ordinary (i.e. not $(q,t)$-deformed) Vandermonde determinant:

$$
\Delta_m(\bar{y}) = \prod_{i \neq j}^m \left(1 - \frac{y_i}{y_j}\right).
\quad (47)
$$

This gives us a hint at what a $3d \ N = 2^*$ theory associated to superquiver looks like: the gauge node (the only one in the example, painted gray in (45)), corresponding to the fermionic root has trivial axial deformation parameter, as if $N = 4$ supersymmetry was unbroken. More generally, for several bosonic roots separated by a fermionic one, the axial mass parameter changes sign along the quiver: e.g. it is $t$ for the bosonic nodes to the left of the fermionic node, and $\frac{q}{t}$ for the bosonic nodes to the right of the fermionic one. On the fermionic node we effectively have the theory with $t = q$.

Finally, as an exercise we draw a colorful picture incorporating various screenings we have obtained:

$$
\begin{array}{c}
\begin{array}{c}
v_1 \quad \cdots \quad v_n \\
y_1 \quad \cdots \quad y_m \\
z_1 \quad \cdots \quad z_k \\
p_1 \quad \cdots \quad p_l \\
w_1 \quad \cdots \quad w_n \\
\end{array}
\end{array}
\quad (48)
$$

The resulting $qW$-algebra \cite{24} should be associated to a certain reduction of a sum of superalgebras $\mathfrak{gl}_{1/2} \oplus \mathfrak{gl}_{2|1}$. The field theory system corresponding to this brane diagram consists of three $3d$ theories each living in its own $S^1 \times \mathbb{R}^2$ space with $\Omega$-background parameters $q$, $t^{-1}$ and $\frac{q}{t}$ respectively:

1. Supersymmetric quiver theory associated to the algebra $\mathfrak{gl}_{2|1}$ on $S^1 \times \mathbb{R}^2$ with axial mass parameters $t$ and $\frac{q}{t}$.

2. Supersymmetric quiver theory associated to the algebra $\mathfrak{gl}_{1|1}$ on $S^1 \times \mathbb{R}^2$ with axial mass parameters $q^{-1}$ and $t$.

3. Theory of free multiplets on $S^1 \times t^{-1} \times \mathbb{R}^2$ with axial mass deformation $q^{-1}$.

Pairs of theories (1, 2) and (2, 3) are coupled by a $1d$ interaction terms.

\footnote{Unfortunately the name superintegral is already taken.}
where the equality follows from the definition of the intertwining operator. Using the coproduct from sec. A.2 we find that on the tensor product of two vector representation and two Fock representations one has

$$\Delta^3(x_0^+)|_{\mathcal{V}_1 \otimes \mathcal{V}_2 \otimes F_{n_1}^{-1} \otimes F_{n_2}^{-1}} = \Delta(x_0^+)|_{\mathcal{V}_1 \otimes \mathcal{V}_2} +$$

$$+ \oint_C \left( \psi^- (z) \otimes \psi^- (z) \right) |_{\mathcal{V}_1 \otimes \mathcal{V}_2 \otimes \Delta(x_0^+)}|_{F_{n_1}^{-1} \otimes F_{n_2}^{-1}}$$

where the integration contour $C$ is a small contour around $z = 0$. Eq. (50) gives the DIM action featuring in the l.h.s. of Eq. (49).

DIM action in the r.h.s. of Eq. (49) is just $\Delta(x^+(z))|_{F_{n_1}^{-1} \otimes F_{n_2}^{-1}}$ (see (61)). Sandwiching both sides of Eq. (49) between the vacuum states, we find that $\Delta(x^+(z))|_{F_{n_1}^{-1} \otimes F_{n_2}^{-1}} |\mathcal{O} \otimes |\mathcal{O}\rangle$ contains only non-negative powers of $z$, as does $|\psi^- (z) \otimes \psi^- (z)\rangle |_{\mathcal{V}_1 \otimes \mathcal{V}_2}$ (see the representations in sec. A.3 and A.4). Thus, the integral in Eq. (50) is equal to the zero mode of $\Delta(x^+(z))|_{F_{n_1}^{-1} \otimes F_{n_2}^{-1}} |\mathcal{O} \otimes |\mathcal{O}\rangle$, i.e. to $(u_1 + u_2)/(1 - q^{-1}) |\mathcal{O} \otimes |\mathcal{O}\rangle$. We have

$$\Delta^3(x_0^+)|_{\mathcal{V}_1 \otimes \mathcal{V}_2 \otimes F_{n_1}^{-1} \otimes F_{n_2}^{-1}} |w_1 \otimes |\mathcal{O}\rangle \otimes |\mathcal{O}\rangle = - \frac{1}{1 - q^{-1}} \langle w_1 | w_2 \rangle |\mathcal{O} \otimes |\mathcal{O}\rangle +$$

$$- \frac{1}{1 - q^{-1}} \left( \begin{array}{c} 1 - \frac{u_1}{w_1} \\ 1 - \frac{q u_2}{w_1} \\ 1 - \frac{q u_2}{w_1} \end{array} \right) |w_1 \otimes |w_2 \rangle |\mathcal{O} \otimes |\mathcal{O}\rangle +$$

$$+ \frac{u_1 + u_2}{(1 - q^{-1})(1 - t)} |w_1 \otimes |w_2 \rangle |\mathcal{O} \otimes |\mathcal{O}\rangle$$

(51)

In the r.h.s. of Eq. (49) we find that $|\mathcal{O} \otimes |\mathcal{O}|\Delta(x_0^+) |$ also reduces to zero modes, which in this case are $|\mathcal{O} \otimes |\mathcal{O}|(1 - q^{-1})^{1/2}$. Substituting both sides of Eq. (49) and denoting the vacuum matrix element of the network by $\psi(w, \bar{w})$ we can write

$$\left( \begin{array}{c} q^{u_1} w_1 + \left( 1 - \frac{t w_1}{u_1} \right) \left( 1 - \frac{q w_2}{w_1} \right) \right) \left( 1 - \frac{q w_2}{w_1} \right) \psi(w_1, \bar{w}_1) = (u_1 + u_2) \psi(w_1, \bar{w}_1)$$

(52)

Factoring the flipping field contributions (see Eq. (22) out of $\psi(w, \bar{w})$ we find that the function

$$\tilde{\psi}(w, \bar{w}) = \left( \begin{array}{c} w_1 \w_2 ; q^{u_1} \\ w_1 \w_2 ; q^{u_2} \end{array} \right) \psi(w, \bar{w})$$

The interaction terms in the Hamiltonian are due to the nontriviality of the DIM coproduct. Denoting
which give rise to two coupled Ruijsenaars Hamiltonians:
The argument of intertwining is completely general, thus any Higgsed network of the form we have
intro-duce/*dash cases they should be described by the elliptic stable envelopes
problems for the networks we have introduced — they should be described by the elliptic stable envelopes
theory.

5 Conclusions and discussions
We have introduced a version of the network formalism based on the DIM algebra intertwiners. It can be
thought of as an analogue of the refined topological vertex formalism for the case incorporating not only
a network of five-branes of Type IIB, but also D3 branes. On the field theory side it provides a way to
understand partition functions (holomorphic blocks) of quantum elliptic and double elliptic systems [35]. It would be interesting to study the monodromy
pictures (48) demonstrates. Some of the networks we have introduced can be compactified, i.e. drawn on a
cylinder or torus instead of a plane. This should give rise to explicit description of the eigenfunctions
of (supersymmetric) Ruijsenaars-Schneider Hamiltonians. On the algebraic side our construction naturally
gives a constructive definition of the partition functions of the theories associated with Dynkin diagrams
and gives a transparent proof of the fact that the partition functions are eigenfunctions
for superalgebras and gives a transparent proof of the fact that the partition functions are eigenfunctions
of (supersymmetric) Ruijsenaars-Schneider Hamiltonians. On the algebraic side our construction naturally
produces screenings for the $qW$-algebras, including those associated with superalgebras.

There are many directions along which one can extend the approach presented here. For example we
have just started studying the 3d theories corresponding to superquivers — there is a wealth of interesting
examples which can be built rather straightforwardly with a simple set of building blocks, as e.g. the picture [48] demonstrates. Some of the networks we have introduced can be compactified, i.e. drawn on a
cylinder or torus instead of a plane. This should give rise to explicit description of the eigenfunctions
of quantum elliptic and double elliptic systems [35]. It would be interesting to study the monodromy
problems for the networks we have introduce — they should be described by the elliptic stable envelopes
theory.

A DIM algebra and its representations
For the sake of completeness in this Appendix we list the relevant formulas from the theory of DIM
algebras, mostly taken from [3] [29].

Their notation differs from the notation here: $(q, t)^{[n]} = (q, t^{-1})^n$
A.1 The algebra

DIM algebra $U_q(t)\widehat{\mathfrak{g}}_1$ is generated by the currents $x^\pm(z) = \sum_{n \in \mathbb{Z}} x_n^\pm z^{-n}$, $\psi^\pm(z) = \sum_{n \geq 0} \psi_n^\pm z^{-n}$ and a central element $\gamma$ subject to the relations:

$$[\psi^\pm(z), \psi^\pm(w)] = 0, \quad \psi^+(z)\psi^-(w) = \frac{g(\frac{w}{z})}{g(\frac{\gamma^{-1} w}{z})} \psi^-(w)\psi^+(z),$$

$$\psi^+(z)x^\pm(w) = g\left(\gamma^{\mp\frac{1}{2}} \frac{w}{z}\right) x^\pm(w)\psi^+(z), \quad \psi^-(z)x^\pm(w) = g\left(\frac{1}{\gamma^{\mp\frac{1}{2}} w/z}\right) x^\pm(w)\psi^-(z),$$

$$[x^+(z), x^-(w)] = \frac{1}{G^{-1}(z)} \left( \delta \left(\gamma^{-1} \frac{z}{w}\right) \psi^+ \left(\gamma^{\frac{1}{2}} w\right) - \delta \left(\gamma^{-\frac{1}{2}} w/z\right) \psi^- \left(\gamma^{-\frac{1}{2}} w\right) \right),$$

$$G^\pm\left(\frac{z}{w}\right)x^\pm(z)x^\pm(w) = G^\pm\left(\frac{z}{w}\right)x^\pm(w)x^\pm(z),$$

where $\delta(x) = \sum_{n \in \mathbb{Z}} x^n$ and the “structure functions” of the algebra are given by $G^\pm(x) = (1 - q^{\pm1}x)(1 - t^{\mp1}x)(1 - t^{\pm1}q^{\mp1}x)$ and $g(x) = G^+(x)/G^-(x)$. Notice that $g(\frac{1}{z}) = \frac{1}{qz}$ and in particular $G^+(1) = G^+(1)$. The ratio of the zero modes $\frac{\psi_0^+}{\psi_0^-} = \gamma_1^2$ also turns out to be central. There are also Serre relations for triple commutators of $x^+(z)$ and $x^-(z)$, which we will not write down here.

Notice that the relations of the algebra are manifestly symmetric under the action of $\mathfrak{g}_3$ group permuting the triplet of deformation parameters $(q, t^\pm, t/q)$. Only part of this symmetry will be retained by the representations which we are going to consider. By this means that some permutations will not affect a representation, while others will turn a representation into an isomorphic one.

DIM algebra respects two gradings, $d$ and $d^\perp$. $d$ counts the number of the Laurent mode of a current, so that $d(x_n^\pm) = d(\psi_n^\pm) = n$, while $d^\perp$ is a “perpendicular” grading defined as $d^\perp(x_n^\pm) = \pm 1$, $d^\perp(\psi_n^\pm) = 0$.

There is an extra symmetry of the DIM algebra, which is not manifest in the definition of $G^\pm(x)$ and $G^-(x)$ — the $SL(2, \mathbb{Z})$ automorphism group (the most tricky part of it is the action of the $S$-element, known as the Miki automorphism). We will not define the action of this symmetry on the currents explicitly. It will be enough for us to visualize it as an action of $SL(2, \mathbb{Z})$ on the double grading lattice $(d, d^\perp) \in \mathbb{Z}^2$ and on the doublet of central charges $(\gamma_1^2, \gamma_2^2)$, so that e.g. $x_n^+ \perp$ is turned into $\psi_{-n}^-$ by the $S$ element.

A.2 The coproduct

DIM algebra can be endowed with a coproduct $\Delta$, which acts on the generators as follows:

$$\Delta(x^+(z)) = x^+(z) \otimes 1 + \psi^- \left(\gamma_{(1)}^\frac{1}{2} z\right) \otimes x^+ \left(\gamma_{(1)} z\right),$$

$$\Delta(x^-(z)) = x^- \left(\gamma_{(2)} z\right) \otimes \psi^+ \left(\gamma_{(2)}^\frac{1}{2} z\right) + 1 \otimes x^- (z),$$

$$\Delta(\psi^\pm(z)) = \psi^\pm \left(\gamma_{(2)}^\frac{1}{2} z\right) \otimes \psi^\pm \left(\gamma_{(1)}^\frac{1}{2} z\right).$$

where $\gamma_{(1)}$ (resp. $\gamma_{(2)}$) denotes the central charge of the first (resp. second) representation in the tensor product. Since the currents are formal infinite Laurent series, the products in the r.h.s. may require regularization for some representations. We will not encounter this problem for the representations we will consider.

The coproduct $\Delta$ respects the $\mathfrak{g}_3$ permutation symmetry of the DIM algebra but is not invariant under the action of $SL(2, \mathbb{Z})$. In fact there is an infinite number of coproducts, parametrized by irrational slopes on the $2d$ plane. All these coproducts are related to each other by nontrivial Drinfeld twists (see [10], and for a more geometric view also [11]).

---

6 This definition differs from the definition of [5] by the rescaling of the generators $x_n^\pm(z) = (1 - q^{\pm1})^{-1}(1 - t^{\pm1})^{-1}x_n^\pm(z)$, while keeping $\psi_n^\pm(z) = \psi_n^\pm(z)$.

7 Curiously, they also appear as factorized scattering matrices of some 2d integrable models. It is tempting to try to understand DIM algebra as a version of the Zamolodchikov-Fateev algebra of such models.

8 The product of the zero modes $\psi_0^+ \psi_0^-$ is central too, but can be eliminated by an overall rescaling of all the currents.
A.3 Horizontal Fock representation

There is a representation of DIM algebra on the Fock space $\mathcal{F}^{(1,0), q, t^{-1}}_u$, generated by the action of creation operators $a_{-n}$, $n \in \mathbb{Z}_{\geq 0}$ on the vacuum vector $|\varnothing, u\rangle$. The states of $\mathcal{F}^{q, t^{-1}}_u$ are therefore labelled by Young diagrams. The combination of indices $(1, 0)$ and $q, t^{-1}$ of the representation is used to denote the “direction” (horizontal) and “length” of its central charge vector $(\gamma^2, \gamma^1) = ((t/q)^1, (t/q)^0) = (t/q, 1)$ respectively. We will usually omit the index $(1, 0)$, when it is clear what is the direction of the central charge vector. Creation and annihilation operators satisfy the commutation relations

$$[a_n, a_m] = n \frac{1-q^n}{1-q^{n+1}} \delta_{n+m, 0}, \quad (64)$$

while the zero modes $P$ and $Q$ commute with $a_n$ and satisfy the standard Heisenberg commutation relations

$$[P, Q] = 1. \quad (65)$$

The zero modes act on the vacuum vector as follows:

$$P|\varnothing, u\rangle = \ln u |\varnothing, u\rangle, \quad e^{\alpha Q}|\varnothing, u\rangle = |\varnothing, e^\alpha u\rangle. \quad (66)$$

The action of the DIM generators is given by the following vertex operators:

$$x^+(z) = (1 - q^{-1})^{-1}(1 - t)^{-1} e^P \exp \left[ \sum_{n \geq 1} \frac{z^n}{n} (1 - t^{-n}) a_{-n} \right] \exp \left[ - \sum_{n \geq 1} \frac{z^{-n}}{n} (1 - t^n) a_n \right], \quad (67)$$

$$x^-(z) = (1 - q)^{-1}(1 - t^{-1})^{-1} e^{-P} \exp \left[ - \sum_{n \geq 1} \frac{z^n}{n} (1 - t^{-n}) \left( \frac{t}{q} \right)^{\frac{n}{2}} a_{-n} \right] \exp \left[ - \sum_{n \geq 1} \frac{z^{-n}}{n} (1 - t^n) \left( \frac{t}{q} \right)^{\frac{n}{2}} a_n \right], \quad (68)$$

$$\psi^+(z) = \exp \left[ - \sum_{n \geq 1} \frac{z^n}{n} (1 - t^{-n}) \left( 1 - \left( \frac{t}{q} \right)^{n/2} \right) a_{-n} \right], \quad (69)$$

$$\psi^-(z) = \exp \left[ \sum_{n \geq 1} \frac{z^n}{n} (1 - t^{-n}) \left( 1 - \left( \frac{t}{q} \right)^{n/2} \right) a_{-n} \right]. \quad (70)$$

The representation $\mathcal{F}^{q, t^{-1}}_u$ is invariant under the exchange of $q$ and $t^{-1}$ deformation parameters. To see this we notice that the exchange $q \leftrightarrow t^{-1}$ in the vertex operators (67)–(69) is equivalent to the rescaling of the creation and annihilation operators:

$$a_n^{(q, t^{-1})} = \frac{1 - q^{-n}}{1 - t^n} a_n^{(t^{-1}, q)}. \quad (71)$$

Notice in particular, that $a_n^{(q, t^{-1})}$ satisfy

$$[a_n^{(t^{-1}, q)}, a_m^{(t^{-1}, q)}] = n \frac{1 - q^{-|n|}}{1 - q^{-|n|}} \delta_{n+m, 0}, \quad (72)$$

as they should. This symmetry might be familiar from the theory of Macdonald polynomials $M^{(q, t^{-1})}_\gamma(a_n^{(q, t^{-1})})$, in which it corresponds to the transposition of the Young diagram $Y$. As we have mentioned above, this $\mathbb{Z}_2$ symmetry of the Fock representation is part of the larger $S_3$ permutation symmetry of the DIM algebra. The remaining elements of $S_3$ transform $\mathcal{F}^{q, t^{-1}}_u$ into two more horizontal Fock representations $\mathcal{F}^{q, t/q}_u$ and $\mathcal{F}^{q^{-1}, t/q}_u$, obtained from (67)–(69) by permuting the parameters of the algebra. Their central charge vectors $(\gamma^2, \gamma^1)$ are $(t^{-1}, 1)$ and $(q, 1)$ respectively.

Fock representation with different slope, e.g. a vertical one $\mathcal{F}^{(0,1), q, t^{-1}}_u$ can be obtained by the action of the elements of $SL(2, \mathbb{Z})$ automorphism group on $\mathcal{F}^{(1,0), q, t^{-1}}_u$. We will not need these representations for the construction presented in the main text, so we omit their explicit definition. For more information on the action of $SL(2, \mathbb{Z})$ and its implications see [5], [15], [16], [17].
A.4 Vertical vector representation

The vertical vector representation $V^q_w$ has trivial central charges $(\gamma^2, \gamma^2_z) = (1, 1)$. It can be understood as a kind of evaluation representation for the currents $x^\pm(z)$, $\psi^\pm(z)$, similar to evaluation representations of (quantum) affine algebra. There are two equivalent ways to view $V^q_w$: either as an infinite dimensional representation parametrized by $w$ with basis $|n,w\rangle$, $n \in \mathbb{Z}$, or as a representation on the space of functions of $w$ with state $|n,w\rangle$ corresponding to function $|q^nw\rangle$. In the first case the action of the DIM currents is

$$
x^+(z)|w, n\rangle = -\frac{1}{1-q^{-1}}\delta\left(\frac{q^nw}{z}\right)|w, n+1\rangle,$$
$$x^-(z)|w, n\rangle = \frac{1}{1-q}\delta\left(\frac{q^{n+1}w}{z}\right)|w, n-1\rangle,$$
$$\psi^+(z)|w, n\rangle = \frac{1-\frac{q^w}{z}}{1-q^w}\left(1-\frac{q^w}{z}\right)|w, n\rangle,$$
$$\psi^-(z)|w, n\rangle = \left(1-\frac{q^w}{z}\right)\left(1-\frac{q^w}{z}\right)|w, n\rangle. \tag{72}$$

In the second view the currents act on functions $|w\rangle$:

$$
x^+(z)|w\rangle = -\frac{1}{1-q^{-1}}\delta\left(\frac{w}{z}\right)|qw\rangle,$$
$$x^-(z)|w\rangle = -\frac{1}{1-q}\delta\left(\frac{w}{qz}\right)|\frac{w}{q}\rangle,$$
$$\psi^+(z)|w\rangle = \frac{1-\frac{q^w}{z}}{1-q^w}\left(1-\frac{1}{q}\right)|w\rangle,$$
$$\psi^-(z)|w\rangle = \left(1-\frac{q^w}{z}\right)\left(1-\frac{1}{q}\right)|w\rangle. \tag{73}$$

We will use both views interchangeably at our convenience.

The vector representation $V^q_w$ is manifestly symmetric with respect to the exchange of $t$ and $\frac{q}{t}$. The action of $S_3$ permutation symmetry of DIM algebra produces two more vector representations $V^{t^{-1}}_w$ and $V^{t/q}_w$ defined in an obvious way.

A.5 Visualizing representations

Let us also mention that both Fock and vector representations can be thought of as certain reductions of a more general MacMahon representation of central charge $(1, K)$ with general $K \in \mathbb{C}$ and states labelled by plane partitions, i.e. $3d$ Young diagrams (here we do not pay attention to the direction of the central charge vector, focusing only on its “magnitude”). As a mnemonic aid, one can view the $3d$ partitions constituting the MacMahon representation as living in a $\mathbb{Z}_{>0}^3$ space with three coordinate axes associated with three parameters $(q, t^{-1}, t/q)$ of the DIM algebra. A reduction of the representation corresponds to restriction to a subset of plane partitions of specific form:

1. Fock representation $F^{q,t^{-1}}_w$ contains plane partitions of unit thickness lying along the $(q, t^{-1})$ plane inside $\mathbb{Z}_{>0}^3$, i.e. those that reduce to Young diagrams. It is evident geometrically, that $F^{q,t^{-1}}_w$ is invariant under the exchange of $q$ and $t^{-1}$ axes and that this symmetry corresponds to the transposition of a Young diagram $Y$ labelling a state of the representation. There are three coordinate planes, and therefore three Fock representations.

2. Vector representation $V^q_w$ can be visualized as single column diagrams towering in the direction associated to $q$. One needs to stretch one’s imagination a little bit in this case, since columns of negative height are also allowed. Naturally, the representation is invariant with respect to the
exchange of coordinate axes $t \leftrightarrow \frac{q}{t}$, which lie perpendicular to $q$. There are three species of vector representations, corresponding to three different orientations of the columns.
