ABSTRACT
Promoting the differentiation of bone marrow mesenchymal stem cells (BMSCs) into osteoblasts is an effective strategy against osteoporosis. Long non-coding RNAs are closely implicated in BMSC osteogenic differentiation. The present study explored the expression pattern and biological role of taurine upregulated gene 1 (TUG1) in osteogenic differentiation. The expressions of TUG1 and osteogenic markers following the osteogenic induction of BMSCs were detected. The functional relevance of TUG1 was evaluated by performing gain- and loss-of-function tests. Inhibitors of AMP-activated protein kinase (AMPK) autophagy were applied to ascertain the effects of TUG1 on the osteogenic differentiation of BMSCs. TUG1 expression increased during the osteogenic differentiation of BMSCs. The overexpression of TUG1 was promoted, whereas the knock-down of TUG1 was suppressed, by BMSC osteogenic differentiation. Mechanically, TUG1 promoted the osteogenesis of BMSCs via the AMPK-mammalian target of rapamycin (mTOR)-autophagy signaling pathway. Blocking AMPK and autophagy could abrogate the osteogenic role of TUG1 in BMSCs. These results demonstrated that TUG1 promoted the osteogenic differentiation of BMSCs by regulating the AMPK/mTOR/autophagy axis, suggesting that targeting TUG1 may be a potential therapy for osteoporosis.

INTRODUCTION
Osteoporosis is a severe metabolic bone disorder in elderly people that occurs due to the imbalance between bone formation and resorption. A family history of fractures, aging, and smoking are considered to be risk factors for osteoporosis. The key to the prevention of osteoporosis is to restore the normal bone content. Patients with osteoporosis are usually treated with calcium supplements and hormone replacement therapy (Armas and Recker, 2012; Coughlan and Dockery, 2014; Compston et al., 2019). Bone marrow mesenchymal stem cells (BMSCs) are multipotent stromal cells that can differentiate into osteoblasts, adipocytes, chondrocytes, etc. The osteogenic differentiation of BMSCs is critical in bone remodeling and the decreased capability of differentiation may be the pathophysiological basis of osteoporosis (Jin et al., 2019; Pierce et al., 2019). Therefore, it is important to elucidate the molecular mechanism of BMSC osteogenic differentiation.

Long non-coding RNAs (lncRNAs) are noncoding transcripts that are longer than 200 nucleotides (Quinn and Chang, 2016). lncRNAs play diverse roles in physiological and pathological processes, such as proliferation, apoptosis, differentiation, migration, and autophagy (Kopp and Mendell, 2018). Deregulated expression of lncRNA has been ob-
served in various human diseases, such as carcinogenesis, cardiovascular disease, and bone-related disorders (Orom and Shiekhattar, 2013). Additionally, the functional relevance of IncRNAs in the osteogenic differentiation of BMSCs has been studied in recent years. For instance, GASS promotes the osteogenesis of BMSCs by functioning as a competing endogenous RNA for miR-135a-5p (Wang et al., 2019). In addition, the DEP domain containing mammalian target of rapamycin (mTOR) interacting protein accelerates osteogenic differentiation by inhibiting the IncRNA MEG3-mediated activation of bone morphogenetic protein 4 (BMP4) signaling (Chen et al., 2018). Taurine upregulated gene 1 (TUG1), located on chromosome 22q12.2, has been widely studied in human malignancies (Li et al., 2016). Knockdown of TUG1 retards osteoblast differentiation in calcific aortic valve disease (Yu et al., 2018). However, whether TUG1 can promote the osteogenic differentiation of BMSCs is currently unknown.

Autophagy is an intracellular degradation process by which cytoplasmic materials are transported to lysosomes for degradation and the content is recycled (Dikic and Elazar, 2018). Autophagy is important for normal physiological behaviors, and autophagic disorder may lead to various diseases, such as cancer, inflammatory disease, and central nervous system malfunction (Levine and Kroemer, 2006). Additionally, autophagy is involved in osteogenic differentiation and bone formation (Yang et al., 2020). Furthermore, AMP-activated protein kinase (AMPK) and mTOR are crucial for autophagy (Kim and Guan, 2015; Herzig and Shaw, 2018). IncRNAs may activate the AMPK signaling pathway and thus, promote autophagy upon energy deficiency (Li et al., 2018). However, whether IncRNA TUG1 can regulate the osteogenic induction of BMSCs via the AMPK/mTOR/autophagy axis is currently unknown. Using gain- and loss-of-function tests, the present study detected the expression and functional relevance of IncRNA TUG1 during osteogenic induction in BMSCs. Furthermore, we explored whether IncRNA TUG1 regulated osteogenesis via activation of the AMPK/mTOR/autophagy axis.

MATERIALS AND METHODS

**BMSC isolation and culture.** BMSCs were isolated from the femora of one-week-old Sprague-Dawley rats. Briefly, collected bone marrow cells were cultured in Dulbecco’s modified Eagle’s medium (DMEM; Invitrogen, Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (Gibco, Grand Island, NY, USA) at 37°C with 5% CO2. The medium was replaced every two days. Cells at passage three were used in this study.

**Transfections.** Transfections of plasmid DNA or siRNAs were performed using the Lipofectamine 3000 (ThermoFisher Scientific, Inc., Waltham, MA, USA) according to the manufacturer’s instructions. BMSCs were seeded onto a 24-well plate and transfected with pcDNA3.1-TUG1, TUG1 siRNA, or their negative controls (GeneChem, Shanghai, China). Then, 48 h later, cells were harvested for further experiments.

**Osteogenic differentiation induction.** To induce osteoblastic differentiation, BMSCs at 90% confluence were cultured in osteogenesis induction medium containing DMEM supplemented with 10% fetal bovine serum, 100 µM L-ascorbic acid, 10 mM of β-glycerophosphate, and 10 mM of dexamethasone at 37°C with 5% CO2. The medium was changed every two days and BMSCs were induced for 21 days.

**Quantitative real-time polymerase chain reaction (qRT-PCR).** Total RNAs from BMSCs were isolated using TRizol reagent (Invitrogen) and reverse transcribed into cDNA using the PrimeScript RT Master Mix (TaKaRa, Dalian, China). PCR reactions were conducted using the SYBR Green PCR master mix (Roche, Basel, Switzerland) to detect the expression of the target genes using the 7900 HT Sequence Detection System (ABI, USA). GAPDH was used as the internal control. The primers used were TUG1: forward 5’-GGCAACAACTCACCCCCAGCAGTCTG-3’, reverse 5’-AGGAGGCAACGGGACTGATTTCC-3’; RUNX family transcription factor 2 (RUNX2): forward 5’-CCAAAGTGGCCAGTTCAACGC-3’, reverse 5’-GGGATGAGGAATGCCGCTTA-3’; bone sialo-protein (BSP): forward 5’-CCGGGAGAACATTTAAGTCCC-3’, reverse 5’-AAAGCCTGCGCCATCCC-3’; osteocalcin (OCN): forward 5’-CAGGTGCAAAAGGCCCAGGAC-3’, reverse 5’-TGGGTCCTCCCAGTCCATTGT-3’; and, collagen type I, alpha 1 (COL1A1): forward 5’-CATGAGCCGAAGCTAACCC-3’, reverse 5’-CTCCATATGACTTCTCGGTCTG-3’.

**Immunofluorescence staining.** For immunofluorescence staining, BMSCs were infected with red fluorescent protein (RFP)-LC3-labeled lentivirus, an autophagic flux reporter comprised of LC3 protein fused with RFP. Red fluorescent signals in the cyto-
plasm indicated autophagosomes. Nuclei were stained with 4′,6-diamidino-2-phenylindole in the dark for 10 min. The LC3+ puncta numbers were examined using a fluorescence microscope (Leica, Germany).

**Western blot.** Proteins from BMSCs were extracted using RIPA Lysis Buffer containing protease inhibitors (Sigma-Aldrich, St. Louis, MO, USA). Protein concentrations were analyzed using the Bradford colorimetric assay. Then, 20 μg of protein per lane was separated using sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE), transferred to a polyvinylidene fluoride (PVDF) membrane, and blocked in skim milk at room temperature for 1 h. The membranes were incubated with the primary antibodies against LC3A (1 : 1000; Abcam, Cambridge, UK), LC3B (1 : 1000; Abcam), RUNX2 (1 : 1000; Abcam), BSP (1 : 1000; Abcam), OCN (1 : 1000; Abcam), and COL1A1 (1 : 1000; Abcam). After horseradish peroxidase-labeled secondary antibodies were added at 37°C for 1 h, the blots were visualized with the ECL detection system. Protein bands were quantified with Quantity One software (Bio-Rad Laboratories, Hercules, USA) for determination of the LC3B/A ratio.

**Alizarin Red staining.** Alizarin Red staining was used to detect the osteoblast mineralization 14 days after osteogenic induction. Cells were washed with PBS, fixed with ethanol for 30 min and stained with Alizarin Red S (Sigma-Aldrich) for 15 min at room temperature. Cells were washed three times with distilled water and then observed under a light microscope.

**Alkaline phosphatase (ALP) staining.** Then, 14 days after osteogenic induction, cells were washed with PBS, fixed with ethanol for 30 min and stained with ALP staining solution (Sigma-Aldrich) in the dark for 15 min at room temperature. Cells were washed three times with distilled water and then observed under a light microscope (Olympus, Japan).

**Enzyme-linked immunosorbent assay.** Then, 14 days after osteogenic induction, cells were washed with PBS and the ALP activity was detected using the ALP assay kit (Sigma-Aldrich) according to the manufacturer's protocol.

**Statistical analysis.** SPSS 20.0 software (SPSS Inc., Chicago, IL, USA) was used for statistical analysis. Experimental data are expressed as mean ± standard deviation. Comparisons between multiple groups were made using ANOVA. A p-value < 0.05 was regarded as statistically significant.

**RESULTS**

**TUG1 expression is elevated during the osteogenic differentiation of BMSCs.** To establish the functional relevance of TUG1 in BMSCs, we first evaluated its expression pattern during the induction of the osteogenic differentiation of BMSCs. TUG1 expression showed a significant increase at 7, 14, and 21 days following the induction of osteogenic differentiation (Fig. 1), suggesting that TUG1 may play a regulatory role during this process.

**TUG1 overexpression promotes the osteogenic differentiation of BMSCs.** Next, we applied gain- and loss-of-function tests to explore the biological effects of the IncRNA of TUG1 during the osteogenic induction of BMSCs. First, 14 days after osteogenic induction, ALP staining and activity were found to be suppressed in TUG1-silenced BMSCs (Fig. 2A, B). Conversely, the overexpression of TUG1 significantly enhanced ALP staining and activity in BMSCs (Fig. 2A, B).

Moreover, we explored the effect of TUG1 on matrix mineralization by performing Alizarin Red staining and studied the expression of the key osteogenic markers by performing qRT-PCR. Alizarin Red staining showed that the depletion of TUG1 attenuated the intensity of Alizarin Red staining, and its overexpression led to aggravated matrix mineralization.

TUG1 promotes the osteogenic differentiation of BMSCs via autophagy

Furthermore, we measured the expression of autophagy markers, i.e., the LC3B/A ratio, in TUG1-overexpressed or silenced BMSCs. At 14 days after osteogenic induction, western blot analysis showed that the depletion of TUG1 decreased the LC3B/A ratio, while the overexpression of TUG1 increased the LC3B/A ratio in BMSCs (Fig. 3A). Additionally, immunofluorescence staining revealed that the number of autophagosomes decreased in TUG1-silenced BMSCs (Fig. 3B). However, the TUG1-overexpressed BMSCs exhibited an increased number of autophagosomes 14 days after the osteogenic induction of BMSCs (Fig. 3B). To ascertain the role of
TUG1 promotes osteogenesis

Fig. 3 TUG1 promotes the osteogenic differentiation of BMSCs via autophagy. BMSCs were transfected with pcDNA3.1-TUG1, TUG1 siRNA, or their negative controls, then induced to osteoblast differentiation for 14 days. (A) Western blot was performed to determine the expression of LC3-A and LC3-B. The ratio of LC3B/A was then calculated. (B) Autophagosomes were detected using immunofluorescence staining, then the number of autophagosomes was calculated. (C) The autophagy inhibitor 3-methyladenine was added to TUG1-overexpressed BMSCs, then cultured for 14 days after osteogenic induction. qRT-PCR was used to determine the mRNA expression of RUNX2, BSP, OCN, and COL1A1. *P < 0.05.

autophagy in TUG1-mediated osteogenic induction, the autophagy inhibitor 3-methyladenine (3-MA) was added to TUG1-overexpressed BMSCs. Consequently, the overexpression of TUG1 promoted the expression of osteogenic-related markers, including RUNX2, BSP, OCN, and COL1A1 (Fig. 3C). How-
TUG1 promotes the osteogenesis of BMSCs via the AMPK/mTOR/autophagy signaling pathway. We then explored the role of the AMPK/mTOR pathway and autophagy in TUG1-induced osteogenesis in BMSCs. At 14 days after osteogenic induction, western blot showed that TUG1-silenced BMSCs exhibited decreased AMPK and P53 expression, whereas the overexpression of TUG1 significantly increased the expressions of AMPK and P53, and decreased mTOR expression in BMSCs (Fig. 4A). Additionally, the AMPK inhibitor BML-275 was added to TUG1-overexpressed BMSCs and then cultured for 14 days. Consequently, the overexpression of TUG1 increased the expression of osteogenic markers (RUNX2, BSP, OCN, and COL1A1) (Fig. 4B). Nevertheless, treatment with AMPK inhibitor abrogated the osteogenic effects of TUG1 in BMSCs, 14 days after osteogenic induction (Fig. 4B). Collectively, these results indicated that TUG1 promotes the osteogenic differentiation of BMSCs via the AMPK/mTOR/autophagy axis.

DISCUSSION
In the present study, we found that TUG1 expression increased during the osteogenic differentiation of BMSCs. Functional assays revealed that TUG1 could promote BMSC osteogenic differentiation via the AMPK/mTOR/autophagy axis.

TUG1, located on chromosome 22q12.2 with a length of 7.1 kb nucleotides, has been extensively studied in various diseases, including neurodegeneration, carcinogenesis, and osteogenic differentiation. TUG1 promotes osteogenic differentiation of periodontal ligament stem cells (He et al., 2018). In the present study, TUG1 showed a significant increase
in expression during the osteogenic differentiation of BMSCs. To unravel the functional role of TUG1 in osteogenic induction, gain- and loss-of-function tests were performed in BMSCs. Results showed that the overexpression of TUG1 facilitated osteogenic differentiation, while TUG1 knockdown delayed the osteogenic induction of BMSCs, suggesting a positive regulator of TUG1 during BMSC osteogenic differentiation.

TUG1 exerts its function via different mechanisms. For instance, Zhang et al. (2014) found that TUG1 is associated with a poor prognosis in lung cancer; moreover, the overexpression of TUG1 promotes tumorigenesis and development via the epigenetic regulation of HOXB7. TUG1 contributes to the carcinogenesis of human osteosarcoma by serving as a competing endogenous RNA for miR-9-5p (Xie et al., 2016). Additionally, TUG1 promotes osteoblast differentiation through the miR-204-5p/Runx2 axis during aortic valve calcification (Yu et al., 2018). In the present study, results showed that the overexpression of TUG1 led to an increase in the LC3B/A ratio and the number of autophagosomes. Moreover, TUG1-overexpressed cells exhibited increased levels of AMPK and P53, and decreased levels of mTOR. These results implied that TUG1 may promote the osteogenic differentiation of BMSCs via the regulation of autophagy and AMPK/mTOR pathway.

Autophagy is a conserved self-degradation system that can clear damaged organelles, metabolites, and pathogens to maintain cellular homeostasis during stress conditions. Dysregulated autophagy is closely associated with human health and disease (Levine and Kroemer, 2008; Dikic and Elazhar, 2018). The mineralization process of osteoblasts is an important step in bone development and metabolism. Abnormal levels of autophagy have critical implications in bone metabolism, mineralization, bone homeostasis, and osteoporosis (Nollet et al., 2014; Vrahnas et al., 2019). AMPK is a type of serine/threonine protein kinase that is implicated in energy metabolism, cell proliferation, differentiation, and apoptosis (Herzig and Shaw, 2018). Activation of the AMPK pathway promotes osteoblast differentiation and mineralization via the regulation of endothelial nitric oxide synthase and BMP (Zhong et al., 2011). To verify whether TUG1 regulates the osteogenic differentiation of BMSCs via autophagy and the AMPK/mTOR signaling pathway, the autophagy and AMPK inhibitors were applied to TUG1 overexpressing BMSCs. Results showed that blocking autophagy and the AMPK pathway abrogated the positive role of TUG1 on BMSC osteogenic differentiation.

Recently, Li et al. (2018) found that the activation of AMPK stimulates osteoblast differentiation and mineralization through autophagy induction, as evidenced by the upregulation of LC3 and p-AMPK and increased autophagosome density. Furthermore, mTOR is an atypical serine/threonine protein kinase and a sensor for amino acids and ATP, which plays a gating role in the process of autophagy (Saxton and Sabatini, 2017). The suppression of mTOR could promote autophagy, which, in turn, regulates autophagy-dependent mTOR activity (Yu et al., 2010). Upon the activation of AMPK, mTORC1 associates from the unc-51-like autophagy activating kinase 1 complex and promotes the formation of the autophagic vesicle membrane (Yu et al., 2018; Lai et al., 2019; Abdrakhmanov et al., 2020). To verify whether the AMPK/mTOR/autophagy axis is involved in TUG1-mediated osteogenic differentiation, the AMPK inhibitor was applied to TUG1-overexpressed BMSCs. Results showed that blocking the AMPK pathway inhibited the positive role of TUG1 on the osteogenic differentiation as well as autophagy level of BMSCs.

In conclusion, the present study demonstrated that the expression of TUG1 was upregulated during the osteogenic differentiation of BMSCs. Mechanically, TUG1 promoted the osteogenic potential of BMSCs by regulating the AMPK/mTOR/autophagy axis. These results suggest that TUG1 may be a new therapeutic target for osteoporosis.
