Abstract. We propose a generalization of the replica trick that allows us to calculate the large distance asymptotics of off-diagonal correlation functions in anyonic models with a proper factorizable ground-state wavefunction. We apply this new method to the exact determination of all the harmonic terms of the correlations of a gas of impenetrable anyons and to the Calogero–Sutherland model. Our findings are checked against available analytic and numerical results.

Keywords: correlation functions, Painlevé equations, cavity and replica method

1. Introduction

Generalized anyonic statistics, which interpolates continuously between bosons and fermions, is considered one of the most remarkable breakthroughs of modern physics. In fact, while in three dimensions particles can be only bosons or fermions, in lower dimensionality they can experience exchange properties intermediate between the two standard ones [1]. In two spatial dimensions, it is well known that fractional braiding statistics can be used to describe the elementary excitations in the quantum Hall effect, motivating a large effort towards their complete understanding.

In one dimension, anyonic statistics are described in terms of fields that at different points \( (x_1 \neq x_2) \) satisfy the commutation relations

\[
\begin{align*}
\Psi^\dagger_A(x_1)\Psi^\dagger_A(x_2) &= e^{i\kappa \pi \epsilon(x_1-x_2)}\Psi^\dagger_A(x_2)\Psi^\dagger_A(x_1), \\
\Psi_A(x_1)\Psi_A(x_2) &= e^{-i\kappa \pi \epsilon(x_1-x_2)}\Psi_A(x_2)\Psi_A(x_1),
\end{align*}
\]

where \( \epsilon(z) = -\epsilon(-z) = 1 \) for \( z > 0 \) and \( \epsilon(0) = 0 \). \( \kappa \) is called a statistical parameter and equals 0 for bosons and 1 for fermions. Other values of \( \kappa \) give rise to general anyonic statistics ‘interpolating’ between the two familiar ones.

Since the second life of one-dimensional gases started following their experimental realization in cold atomic setups [2], there have been several proposals for creating and manipulating anyons [3], even in one dimension. A few 1D anyonic models have been introduced and investigated [4]–[26]. In this paper we consider the calculation of
off-diagonal correlation (or one-particle density matrix) for a system of $N$ particles:

$$g_\kappa^\kappa(x) = \rho_\kappa^\kappa(x) = \langle \Psi^\kappa_\kappa(x) \Psi^{\kappa}_\kappa(0) \rangle,$$

for models that have a factorizable many-body ground-state wavefunction:

$$\Phi_\kappa(x_1, \ldots, x_N) = C_N \prod_{k<l} f(e^{2\pi i x_k/L} - e^{2\pi i x_l/L}) B_\kappa(x_k - x_l),$$

with $f(x)$ a generic even function, $C_N$ a normalization constant, and

$$B_\kappa(x) = \begin{cases} e^{-i\pi \kappa} & x < 0, \\ 1 & x > 0, \end{cases}$$

completely specifying the statistic. Among these models, the more relevant are the anyonic generalizations of the Tonks–Girardeau gas and of the Calogero–Sutherland model.

In this paper we propose a generalization of the replica trick that is able to select the correct anyonic branch in the replicated space. The use of this replica method started in the context of the diagonal correlation of the Calogero–Sutherland model [27], was later extended to a gas of impenetrable bosons [28, 29], and was finally extended to the off-diagonal correlation of the Calogero–Sutherland type, but only for bosonic and fermionic statistics [30]. It has been already proposed [28] that in the replica approach one deals with two functions of the replica number $n$, one for fermions and one for bosons, or better a single function with two branches, a fermionic one and a bosonic one, that coincide only for integer $n$. Here we push forward this interpretation and we claim that the replicated correlation has an infinite number of branches corresponding to the different anyonic statistics. The apparent lack of rigor of this approach (that is shared by most replicas calculations starting from the celebrated Parisi mean-field solution of the spin glass [31]) can be justified by the amazingly simple final results that agree with all the available analytics and with the direct numerical calculations. The analytic continuation that we propose in this paper allows us to obtain exact asymptotic expansions for large distances that are valid for the off-diagonal correlation for general anyonic parameter $\kappa$.

We also exploit the property that the anyonic correlation function satisfies a Painlevé V differential equation [21], that allows a rigorous analytic check of the results obtained through replicas. To further check the replica predictions, we perform a careful numerical comparison of the finite-size off-diagonal correlation obtained via the Toeplitz determinant representation [8, 21].

The work is organized as follows. In section 2 we introduce the anyonic Tonks–Girardeau gas and the strategy for the replica calculation. In section 3, starting from the example of a simple integral we show how to select the correct anyonic statistic from the replicas. In section 4 we review the replica calculation for the bosonic impenetrable gas following [28]. In section 5 we apply the replicas to the anyonic Tonks–Girardeau gas, showing that all the harmonic terms in the large distance expansion are captured by the saddle-point approximation in the replica space. In section 6 we calculate the corrections to the saddle-point approximation, both using perturbation theory and via the solution of the Painlevé V equation. In section 7 we compute numerically the off-diagonal correlation function, showing perfect agreement with the analytic results. In section 8 we use the replica trick to obtain the correlation function in the fully anyonic Calogero–Sutherland model. Finally in section 9 we draw our conclusions.
2. The anyonic Tonks–Girardeau gas

In first-quantization language, the Lieb–Liniger Hamiltonian is

$$H = -\sum_{i}^{N} \frac{\partial^2}{\partial x_i^2} + 2c \sum_{1 \leq i < j \leq N} \delta(x_i - x_j),$$

(5)

where the $N$-anyon ground-state function exhibits generalized symmetry under the exchange of particles. For $\kappa = 0$ the model reduces to the bosonic Lieb–Liniger [32] form, while for $\kappa = 1$ it reduces to free fermions. The Tonks–Girardeau gas is obtained for $c \to \infty$ and corresponds to impenetrable anyons. In this limit, the ground-state wavefunction has the form of equation (3) with $f(y) = |y|$. This anyonic model has been explicitly studied in [4, 7, 5, 8, 11, 12, 22, 21, 24].

The anyonic one-particle density matrix for $N + 1$ particles can be written [8] as an $N$-dimensional integral (in the variables $x_j/L = t_j$ and $t = x/L$):

$$\rho_{N+1}^{\kappa}(t) = \frac{1}{(N + 1)!} \int_{0}^{1} dt_1 \cdots \int_{0}^{1} dt_N$$

$$\times \prod_{s=1}^{N} B_\kappa(t_s - t) \sin[\pi(t_s - t)] \sin[\pi t_s] \prod_{1 \leq i < j \leq N} 4 \sin[\pi(t_j - t_i)]^2.$$

(6)

Using the identity

$$\prod_{1 \leq j < k \leq N} 4 \sin[\pi(t_j - t_k)]^2 = \prod_{1 \leq j < k \leq N} |e^{i2\pi t_k} - e^{i2\pi t_j}|^2 \equiv |\Delta_N(t_i)|^2,$$

(7)

we can identify the second product in the integral (6) with the square of the absolute value of a Vandermonde determinant. Thus the reduced density matrix is an average over the distribution $|\Delta_N|^2$:

$$\rho_{N+1}^{\kappa}(t) = \left\langle \prod_{s=1}^{N} B_\kappa(t_s - t) |z - z_s||1 - z_s| \right\rangle_{|\Delta_N|^2},$$

(8)

where $z_s = e^{i2\pi t_s}$ and $z = e^{i2\pi t}$.

In the case of bosons ($\kappa = 0$) the reduced density matrix can be obtained [28] through a replica trick, considering for a positive integer $n$

$$Z_{2n}^{\kappa=0}(t) = \left\langle \prod_{s=1}^{N} (z - z_s)^{2n}(1 - z_s)^{2n} \right\rangle_{|\Delta_N|^2},$$

(9)

and then $\rho_{N+1}^{\kappa}(t)$ is obtained from $Z_{2n}(t)$ by a suitable analytic continuation to $n \to 1/2$. It has been shown by Kurchan [33] that to obtain the average of the absolute value from the replicated correlation, we have to require that the analytic continuation for any complex $n$ with positive real part should diverge at maximum as a power law.

How do we modify such replica calculation to anyons when we deal with averages over a function of unitary modulus but with arbitrary phase? Our trick is to start by considering an anyonic parameter that is a rational number, i.e. $\kappa = q/p$ with $p$ and $q$ integer.
We can then consider
\[
Z_{2np}(t) = \left\langle \prod_{s=1}^{\Delta N} (z - z_s)^{2np}(1 - z_s)^{2np} \right\rangle_{|\Delta N|^2},
\]
that, after a proper analytic continuation, for $2np \to 1$ could give the desired reduced density matrix. The ambiguity in this case is obvious; in fact $Z_{2np}$ includes all the correlations of anyons with statistical parameter $\kappa = q/p$ for any $q = 1, \ldots, 2p$. This means that different analytic continuations will give different anyonic correlations including bosonic and fermionic ones. We will propose a general criterion that would allow us to choose the proper analytic continuation for any value of the statistical parameter. To elucidate the meaning of our trick we start by applying it to a trivial integral that contains all the essence of the modified replica trick.

3. The replica trick for an integral

Let us consider the integral
\[
I = \int_{-\infty}^{+\infty} dt \, |t| e^{-t^2} = 1,
\]
that has the replica representation
\[
I_{2n} = \int_{-\infty}^{+\infty} dt \, t^{2n} e^{-t^2} = \frac{1 + e^{2\pi in}}{2} \Gamma(1/2 + n).
\]
Notice that $I_1 = 0$; while considering $n$ integer and analytically continuing we have $I_{2n} = \Gamma(1/2 + n)$, which leads to $I_{2n} = 1$, the desired result. This analytic continuation selected the ‘bosonic’ branch of the integral, giving the integral with the absolute value, because it is the only analytic continuation that does not diverge exponentially in the complex plane for $n \to \infty$, i.e. that satisfies the Kurchan criterion for the absolute value \[33\]. Oppositely, taking directly $I_{2n}$, we would have obtained the ‘fermionic’ branch.

Let us then modify the integral anyonically:
\[
I^\kappa = \int_{-\infty}^{+\infty} dt \, B_\kappa(t) |t| e^{-t^2} = \frac{1 + e^{-i\pi q/p}}{2} \Gamma(1/2 + np),
\]
with $B_\kappa(t)$ given by equation (4) and $\kappa = q/p$. The proposed analytic continuation is
\[
I_{2np} = \int_{-\infty}^{+\infty} dt \, t^{2np} e^{-t^2} = \frac{1 + e^{2i\pi np}}{2} \Gamma(1/2 + np),
\]
where we lose any knowledge of the value of $q$; that is the previously mentioned ambiguity. Considering $n$ and $p$ integers and analytically continuing, one would always get the bosonic branch. On the other hand, one can play the following game:
\[
I_{2np} = \frac{1 + e^{-2i\pi np} e^{2i\pi n(p+q)}}{2} \Gamma(1/2 + np),
\]
with $q, p, n$ integers. Considering the analytic continuation
\[
I_{2np}^q = \frac{1 + e^{-2i\pi np}}{2} \Gamma(1/2 + np),
\]
doi:10.1088/1742-5468/2009/03/P03002 5
we get
\[ I_1^q = \frac{1 + e^{-i\pi q/p}}{2}, \] (17)
that selects the desired anyonic branch. This simple game works because \( I_{2np}^q \) is the only analytic continuation which has the correct asymptotic behavior for large imaginary \( n \) (and positive real part) that selects the correct branch. The message is that the integral \( I_{2np}^q \) contains all statistics from bosons to fermions and a given one can be obtained just by selecting the correct behavior at large imaginary \( n \).

With this observation in mind, we can then use the result \( Z_{2n}(t) \) for the bosonic Tonks–Girardeau gas and for the Calogero–Sutherland model. Properly continuing \( Z_{2np}(t) \), we easily get the anyonic result. Thus in the next section we review the bosonic result and in the following one we generalize it to anyons.

### 4. Boson review

All the content of this section is taken from the pioneering work of Gangardt [28]. We report this material here only to make this paper self-contained.

The replicated average for boson equation (9) is (we recall that \( z = e^{2\pi it} \))
\[
Z_{2n}(t) = \frac{1}{M_N(2n)} \int_{-1/2}^{1/2} d^N t |\Delta_N(e^{2\pi it})|^2 \prod_{s=1}^N |1 + e^{2\pi it_s}|^{2n} + e^{2\pi it_s}|^{2n}, \tag{18}
\]
where we have normalized \( Z_{2n}(1) = 1 \), introducing the constant \( M_N(2n) \) (see [28] for its precise value; it is not essential for what follows). The integral (18) has a dual representation [34] by an integral over \( n \) variables:
\[
Z_{2n}(t) = \frac{z^{-Nn}}{S_{2n}} \int_0^1 d^{2n} x \Delta_{2n}^2(x) \prod_{a=1}^{2n} (1 - (1 - z)x_a)^N, \tag{19}
\]
where the normalization constant is given by the Selberg integral
\[
S_{2n} = \int_0^1 d^{2n} x \Delta_{2n}^2(x) = \prod_{a=1}^{2n} \frac{\Gamma^2(a)\Gamma(1+a)}{\Gamma(2n+a)}. \tag{20}
\]
In equation (19) the number of particles \( N \) appears only as a parameter. This representation allows us to obtain the asymptotic expression for \( Z_{2n} \) suitable for analytic continuation in \( n \). In the large \( N \) limit the integrand in (19) oscillates rapidly and the main contribution comes from the end-points \( x_\pm = 1, 0 \) which are the only stationary points of the phase. We change variables near each end-point:
\[
x_a = 0 + \frac{\xi_a}{N(1-z)}, \quad a = 1, \ldots, l, \tag{21}
\]
\[
x_b = 1 - \frac{\xi_b}{N(1-z^{-1})}, \quad b = l + 1, \ldots, 2n.
\]
The integrand in (19) simplifies in the large $N$ limit:

$$(1 - (1 - z)x_\alpha)^N \approx \begin{cases} e^{-\xi_a}, & a = 1, \ldots, l \\ z^N e^{-\xi_a}, & a = l + 1, \ldots, 2n \end{cases}$$

and the integration measure including the Vandermonde determinant is factorized as

$$d^{2n}x \Delta^2_{2n}(x) = \frac{d^l \xi_a \Delta^2_l(\xi_a) d^{2n-l} \xi_b \Delta^2_{2n-l}(\xi_b)}{[N(1 - z)]^{l^2} [N(1 - z^{-1})]^{(2n-l)^2}}. \quad (23)$$

The remaining integrals are calculated using [36]–[38]

$$I_l(\lambda) = \int_0^\infty d^l \xi_a \Delta^2_l(\xi_a) \prod_{a=1}^l e^{-\lambda \xi_a} = \lambda^{-l^2} \prod_{a=1}^l \Gamma(a) \Gamma(1 + a). \quad (24)$$

Multiplying the contribution of each saddle point by the number of ways to distribute variables we obtain the asymptotic form of the integral (19) as a sum of $2n + 1$ terms$^3$:

$$Z_{2n}(t) = \prod_{c=1}^{2n} \frac{\Gamma(2n + c)}{\Gamma(c)} \sum_{l=0}^{2n} (-1)^{2n(n-l)} \left[ F_{2n}^l \right] \frac{2 N^{(N+2n)(n-l)}}{(2X)^{l^2+(2n-l)^2}}, \quad (25)$$

where we have introduced $X = N(z^{1/2} - z^{-1/2})/2i = N \sin \pi t$ and the factors $F_{2n}^l$:

$$F_{2n}^l = \prod_{a=1}^l \frac{\Gamma(a)}{\Gamma(2n - l + a)} = \frac{G(l+1) G(2n-l+1)}{G(2n+1)}, \quad (26)$$

where $G(x)$ is the Barnes $G$-function:

$$G(z + 1) = (2\pi)^{z/2} e^{-(z + (\gamma_E + 1)z^2)/2} \prod_{k=1}^\infty (1 + z/k)^k e^{-z^2/(2k)}, \quad (27)$$

$\gamma_E$ is the Euler constant, $G(1) = G(2) = 1$, and $G(3/2) = 1.069\,22 \cdots$. Using the Barnes function is particularly useful for getting the analytic continuation easily. Notice that also at this level, if we set $2n = 1$ in equation (25) we still get the fermion result $g_{l=1}(x) = \sin((N + 1)\pi t)/((N + 1)\sin \pi t)$.

For $n$ integer, we can extend the sum from $0 \leq l \leq 2n$ to all the integers, because $F_{2n}^l$ vanishes for $l < 0$ and $l > 2n$ (it is a simple property of the Barnes $G$ function inherited from the $\Gamma$). While this is an innocuous change for integer $n$, it is the fundamental step that will allow for replica symmetry breaking, because for general values of $n$ (i.e. non-integers), $F_{2n}^l$ is non-zero for any $l$ and the sum results in a true infinite series. Changing the summation variable to $k = l - n$ we obtain finally

$$Z_{2n}(t) = \prod_{c=1}^{2n} \frac{\Gamma(2n + c)}{\Gamma(c)} \left( G^4(3/2) + 2 \sum_{k=1}^\infty (-1)^{2nk} [F_{2n}^{k+n}]^2 \cos \frac{2k \pi (N + 2n)t}{(4N^2 \sin^2 \pi t)k^2} \right)^3. \quad (28)$$

$^3$ We corrected an error/typographical error, irrelevant in the limit $n \rightarrow 1/2$, from [28], i.e. a factor that is 1 when $n \rightarrow 1/2$.  

doi:10.1088/1742-5468/2009/03/P03002
This apparently useless shift is the crucial point where the replica symmetry is finally broken because it selects the zero mode. Now we are in a position to take the limit \( n \to 1/2 \) which results in the desired harmonic expansion of the one-body density matrix

\[
\rho_{N+1}(t) = \frac{1}{|2N \sin \pi t|^{1/2}} \left[ \sum_{k=-\infty}^{\infty} (-1)^k [G(3/2 + k)G(3/2 - k)]^2 \cos 2k \pi (N + 1)t \right].
\]

The form of this expansion was first predicted by Haldane [35], but the complete knowledge of the whole amplitude was only obtained by means of replicas [28].

5. The anyons

In the calculation of \( Z_{2np} \) everything proceeds like in the calculation for bosons, leading to the replacement \( n \to np \) in the replicated correlation (25):

\[
Z_{2np}(t) = \prod_{c=1}^{2np} \frac{\Gamma(2np + c)}{\Gamma(c)} \sum_{m=-\infty}^{\infty} (-1)^{2np(np-m)} \frac{[F_{2np}^{np-2m}]^2 z^{(N+2np)(np-m)}}{(2X)^{2(np-m)^2 + (np+np+2m)^2}}.
\]

The correct analytic continuation for getting the anyonic branch with \( \kappa = q/p \) is obtained by selecting the behavior at large imaginary \( n \). As for bosons, this is obtained by choosing the zero mode in the sum over \( l \) and then by extending the sum over all integers. Thus we set

\[
np - l = nq + m,
\]

which, amazingly, is the only change that we need, for describing anyons, from the bosonic formulae. With this substitution we get

\[
Z_{2np}^q(t) = \prod_{c=1}^{2np} \frac{\Gamma(2np + c)}{\Gamma(c)} \sum_{m=-\infty}^{\infty} (-1)^{2np(nq+m)} \frac{[F_{2np}^{np-nq-m}]^2 z^{(N+2np)(nq+2m)}}{(2X)^{(np-(nq+2m))^2 + (np+2m+2nq)^2}},
\]

which is ready for the analytic continuation \( 2np \to 1 \), yielding

\[
\rho_{N+1}^{q/p}(z) = \sum_{m=-\infty}^{\infty} (-1)^{(n/2+p)} \frac{[F_{1/2}^{2p+2m}]^2 \sin(N+1)(q/2p+m)}{(2X)^{1/2 + 2(m+q/2p)^2}},
\]

where only the ratio \( \kappa = q/p \) appears and so it can be generalized to any \( \kappa \), not only ratios of integers, giving (restoring \( z = e^{i2\pi x/L} \))

\[
\rho_{N+1}^{q/p}(x) = \sum_{m=-\infty}^{\infty} (-1)^{\kappa/2 + m} \frac{[G((3/2) - (\kappa/2) - m)G((3/2) + (\kappa/2) + m)]^2 e^{i\pi x(\kappa + 2m)(N+1)/L}}{(2N \sin \pi x/L)^{1/2 + 2(m+\kappa/2)^2}}.
\]

According to bosonization (or the harmonic fluid approach), any anyonic off-diagonal correlation in the thermodynamic limit \( N \to \infty \) with \( \rho_0 = N/L \) kept constant admits the expansion [11]

\[
g_1(x) = \rho_0 \rho_{\infty} \sum_{m=-\infty}^{\infty} b_m e^{i(2m+\kappa)\pi p \rho_0 x} e^{-i(m+\kappa/2)\rho_0} \frac{e^{i(2m+k)\pi x}}{(2m+k)^2/2L + (1/2K)}.
\]
Here \(d(x) = |L \sin(\pi x/L)|\), \(b_m\) are unknown non-universal amplitudes, while \(K\) is the universal Luttinger liquid exponent equal to 1 for the Tonks–Girardeau case (we fixed \(b_0 = 1\)). The two expansions agree perfectly, confirming the correctness of the result. Furthermore, we obtained an exact expression for all the coefficients in the harmonic expansion:

\[
\rho_{\infty} b_m = \frac{[G((3/2) - (\kappa/2) - m)G((3/2) + (\kappa/2) + m)]^2}{2^{1+2(m+\kappa/2)^2}}
\]

with \(\rho_{\infty} = \frac{[G((3/2) - (\kappa/2))G((3/2) + (\kappa/2))]^2}{\sqrt{2}}\). \(\text{(35)}\)

The leading term \(\rho_{\infty}\) has already been obtained from the Fisher–Hartwig conjecture applied to the Toeplitz determinant [8, 21], and the two results agree. All the other terms are new. It is important to write down the ratio of two consecutive amplitudes:

\[
\frac{b_{m+1}}{b_m} = -\left[\frac{\Gamma(3/2 + \kappa/2 + m)}{\Gamma(1/2 - \kappa/2 - m)}\right]^2 4^{1+2\kappa+2m}. \quad \text{(36)}
\]

The first corrections to the leading behavior are given by the terms with \(m = \pm 1\), which satisfy

\[
b_1 b_{-1} = \frac{1}{2N(1 - \kappa^2)^2}. \quad \text{(37)}
\]

We will see that the same result also follows from the Painlevé V equation, giving a further check of the replica approach.

6. Beyond the saddle points

The formula just derived gives the leading term in \(1/N\) of the desired correlation function. As is well known, this does not give all the dominating terms in the thermodynamic limit, defined as \(N \to \infty\) with \(N\pi x/L = k_F x\) taken constant. One then needs to calculate corrections to the previous terms. A systematic way to get these corrections is to perform the perturbation theory close to the saddle points order by order, considering in equation \((21)\) the full expansion in \(\xi_{a,b}\) close to \(x = 0, 1\), as was done in [28] for bosons. This approach is very general and straightforward and gives all the \(1/N\) corrections, but unfortunately soon becomes computationally cumbersome, increasing the order. For this reason, we only report the first-order computation in section 6.1. Alternatively, we can take a different approach based on the solution of the Painlevé V equation, that gives very easily all the terms in the expansion, but only in the thermodynamic limit.

6.1. The first order in perturbation theory

In [28] the first-order correction in \(1/N\) to \(Z_{2n}(t)\) has been explicitly calculated (see equation \((65)\) there). Using this result and simply imposing \(2n \to 2np\) and then performing the shift \(np - l = nq + m\), we get for the first-order term (we recall that \(X = N \sin \pi t\), so it is \(O(N)\))

\[
\frac{i}{X}(np - nq - m)(np + nq + m)[(np + nq + m)e^{i\pi x} - (np - nq - m)e^{-i\pi x}]
\]

\[
- \frac{1}{N}[(np + nq + m)^3 + (np - nq - m)^3], \quad \text{(38)}
\]

doi:10.1088/1742-5468/2009/03/P03002
and taking $2np \to 1$ and then considering only the zero mode $m = 0$ (higher modes give rise to higher corrections in $1/N$), we get

$$- \frac{1}{2N} (1 + \kappa^2) + i \frac{1 - \kappa^2}{4N} \frac{1}{\kappa} \tan \frac{\pi x}{L}. \quad (39)$$

Notice that for bosons and fermions ($\kappa = 0, 1$) the tan correction is absent: the role of this term in the replica approach is only understood while studying anyons. The first term $-(1 + \kappa^2)/2N$ just corresponds to the natural replacement $N \to N + 1$ in the denominator of the leading term.

### 6.2. Large distance asymptotic expansion via the Painlevé V equation

In [21] we have shown that $\rho_\kappa(t)$ for finite $N$ satisfies a second-order differential equation of Painlevé VI type. The differential equation does not depend on the anyonic parameter, i.e. it is the same for any $\kappa$. What characterize the statistic are the boundary conditions at $t = 0$ that do depend on the anyonic parameter. It is well known that in the thermodynamic limit, the Painlevé VI equation reduces to a Painlevé V form (see e.g. [36, 39, 40]) that was first derived for bosons by Jimbo et al [41]:

$$(x\sigma'' + 4(x\sigma' - 1 - \sigma)(x\sigma' + \sigma^2 - \sigma) = 0, \quad (40)$$

with $\sigma(x) = x \frac{d \log \rho(x)}{dx}$. \quad (41)

To get a systematic expansion for large $x$ from this equation we need to impose the anyonic boundary conditions at $x = \infty$. We need the knowledge of the first two leading terms in the harmonic fluid expansion, $b_0$ and $b_1$. Actually $b_0$ gives only the overall normalization; in fact $\sigma(x)$ does not depend on it, while $b_{-1}$ is essential for fixing all the signs (in fact an old sign error in $b_{-1} = b_1$ for bosons [42] caused all the expansions in [41] to have the wrong signs. This has been corrected only in [28]).

In this section we set $k_F = 1$ for simplicity in writing; the correct formulae are obtained by making the replacement $x \to k_F x$. The complete asymptotic expansion of $\rho(x)$ is obtained by multiplying any term in the harmonic expansion (34) by an analytic function at $x = \infty$, i.e.

$$\rho(x) = \rho_\infty e^{i\kappa x} \frac{\kappa}{{x}^{1/2 + \kappa^2/2}} \left[ \left(1 + \frac{d_1}{x} + \frac{d_2}{x^2} + \cdots \right) + b_{-1} \frac{e^{-2ix}}{x^{2-2\kappa}} \left(1 + \frac{a_1}{x} + \frac{a_2}{x^2} + \cdots \right) \right. \right.$$

$$+ b_1 \frac{e^{2ix}}{x^{2+2\kappa}} \left(1 + \frac{c_1}{x} + \frac{c_2}{x^2} + \cdots \right) + \cdots \right]. \quad (42)$$

From this we have the large distance expansion of $\sigma$ that fixes the boundary conditions:

$$\lim_{x \to \infty} \sigma(x) = i\kappa x - \frac{1 + \kappa^2}{2} - 2ib_{-1} e^{-2ix} x^{-1+2\kappa} + O(x^o), \quad (43)$$

where $o$ is some exponent not better specified, that will follow from the equation. Plugging this expansion in the Painlevé equation one can get iteratively all the various coefficients $a_i, b_i, c_i, d_i$. The first term in this expansion is equation (37), which provides a further consistency check of the replica approach. After long and tedious algebra we obtained the
Figure 1. Dependence on the anyonic statistic parameter $\kappa$ of the coefficients of the large distance expansion of the off-diagonal correlators, equations (42) and (50).

first coefficients:

\begin{align*}
    d_1 &= i\kappa \frac{1 - \kappa^2}{4}, \\
    c_1 &= -i \frac{(1 + \kappa)(2 + \kappa)(3 + \kappa)}{4}, \\
    a_1 &= i \frac{(1 - \kappa)(2 - \kappa)(3 - \kappa)}{4}, \\
    d_2 &= \frac{1 - \kappa^2}{32}(\kappa^4 + 4\kappa^2 - 1), \\
    a_2 &= -\frac{1}{32}(3 - \kappa)(1 - \kappa)(31 - 48\kappa + 28\kappa^2 - 8\kappa^3 + \kappa^4), \\
    c_2 &= -\frac{1}{32}(3 + \kappa)(1 + \kappa)(31 + 48\kappa + 28\kappa^2 + 8\kappa^3 + \kappa^4),
\end{align*}

which for $\kappa \to 0$ reproduce the known result for bosons [28, 41]. Notice that $d_1$ reproduces the result from first-order perturbation theory. In figure 1 we report all these coefficients as functions of $\kappa$. Notice that since at the fermionic point all but two of the terms must vanish, we have $a_m = d_m = 0$ for any $m$, while the vanishing of the other terms is ensured by $b_1 = 0$. At the bosonic point however, the reality of the correlator implies $a_i = c_i^*$, which is satisfied by our expressions.
7. The comparison with numerics

In this section we show how our expansions fit perfectly with the numerical data obtained by the exact evaluation of the off-diagonal correlators at finite $N = L$ through the evaluation of the Toeplitz determinants derived in [8, 21].

At finite volume and unit density, the expansion can be written as

\[
\rho(x) = \frac{\rho_{\infty} e^{ikx}}{[N \sin \pi x/L]^{(1/2)+(\kappa^2/2)}} \left[ 1 + O(N^{-2}) \right] + \frac{d_1}{N \tan \pi x/L} + \frac{d_2}{[N \sin \pi x/L]^2} + O(N^{-3}) \\
+ b_{-1} \frac{e^{-2iNx}}{[N \sin \pi x/L]^{2 - 2\kappa}} \left( 1 + \frac{a_1}{N \tan \pi x/L} + \frac{a_2}{[N \sin \pi x/L]^2} + O(N^{-3}) \right) \\
+ b_1 \frac{e^{2iNx}}{[N \sin \pi x/L]^{2 + 2\kappa}} \left( 1 + \frac{c_1}{N \tan \pi x/L} + \frac{c_2}{[N \sin \pi x/L]^2} + O(N^{-3}) \right) \\
+ \text{higher harmonics}. \tag{50}
\]

Notice that we have used in the leading term $N$ instead of $N - 1$ to cancel the $1/N$ correction to the constant in the first line, according to equation (39). It has been shown already in [8] that just the leading term in this expansion (obtained from the Fisher–Hartwig conjecture) describes $\rho(x)$ almost perfectly for all $\kappa < 1/2$. In [11] it has been argued that for larger values of $\kappa$ the first harmonic (i.e. $b_{-1}$) is fundamental for having a good description of the asymptotic results because its power $2 - 2\kappa$ gets closer to zero. Including this term, we have a perfect description of the asymptotic behavior [11], but the exact value of the amplitude $b_1$ has only been obtained here.

Why wonder about further corrections? The main reason for caring about them is that they give rise to non-analytic terms in the momentum distribution function at $k = \kappa + nk_F$ whose exact structure is characterized by the coefficients $b_n$. Furthermore they give visible corrections to the off-diagonal correlators if we carefully search for them. This is elucidated in the three figures 2–4 where we report $\rho(x)$ for $\kappa = 0.1$ and $N = 81$, for $\kappa = 0.5$ and $N = 101$, and for $k = 0.9$ and $N = 121$ respectively. In the three figures, the top panels show the real (left) and imaginary (right) parts of $\rho(x)$ directly calculated from the Toeplitz determinant. In the second panels from the top we report real and imaginary parts of

\[
\rho_{\text{corr}}(x) = \frac{\rho(x)}{\rho_{\text{FH}}(x)} - 1 = \frac{\rho(x)[N \sin \pi x/L]^{(1/2)+(\kappa^2/2)}}{\rho_{\infty} e^{ikx}} - 1, \tag{51}
\]

that should tend to zero for $N \to \infty$ for any $\kappa \neq 1$ (at $\kappa = 1$, the first harmonic $b_{-1}$ is of order $O(N^0)$). We can in fact see that these are much smaller than the leading contribution for $\kappa$ far from 1, but become very relevant at $\kappa = 0.9$ also at $N = 121$. Furthermore the second panels show very interesting oscillating behavior due to the first harmonics. Thus, in order to kill the first oscillating behavior we subtract from $\rho_{\text{corr}}(x)$ the first oscillating terms in equation (50), i.e. the terms in $b_{\pm 1}$. This subtraction is shown in the set third from the top of panels. The effect of this subtraction is rather peculiar. In fact while for $\kappa = 0.1$ it mainly kills the oscillations, leaving the absolute value almost unchanged because of the smallness of the exponent in $b_{\pm 1}$, for larger $\kappa$ the absolute value goes down drastically, but strong oscillations are still present. The left oscillations are the
Figure 2. Off-diagonal correlation function for $\kappa = 0.1$ and $N = 81$. Top panels: real (left) and imaginary (right) parts of $\rho^{0,1}_{01}(t)$. Second rows: $\rho^{0,1}_{01}(t)/\rho_{FH}(t) - 1$. Third rows: subtraction of the first two harmonic terms $b_{\pm 1}$. Fourth rows: further subtraction of the analytic contributions $d_{1,2}$. Bottommost panels: Further subtraction of the analytic corrections to the harmonic terms $a_1$ and $c_1$.

second harmonics $b_{-2}$. In the imaginary part of what is left, one can clearly recognize a $1/\tan \pi x/L$ shape due to the term $d_1$ for any value of $\kappa$. In fact, by subtracting the $d_1$ term, as shown in the right fourth from top panels, the value goes still drastically down by one or two orders of magnitude. In contrast, the real part at the third level has a shape depending on $\kappa$. This is very easily understood: for $\kappa < 1/2$ the larger term left in the expansion is $d_2$, going always like $N^{-2}$, while for $\kappa > 1/2$ it is the term in $a_1$ going like $3 - 2\kappa$. At $\kappa = 1/2$ the two terms are both $N^{-2}$, but $d_2$ being very close to zero (see figure 1), the most important term is $a_1$. For these reasons, in the left fourth panel there is shown for $\kappa = 0.1$ the subtraction of $d_2$ and in the other two cases the subtractions of $a_1$ and $c_1$. Evidently these subtractions are the correct ones and in fact they decrease the value considered by at least one order of magnitude. Finally in the bottommost panel we report the final subtractions left of $a_1$, $c_1$ or $d_2$ depending on the case. A further reduction of the value is observed. Clearly this procedure of subtraction can be repeated ad lib, obtaining better and better agreement, but we preferred to stop at this level.

A last comment concerns the absolute value of the real part of these corrections, which is small, but non-vanishing, as is evident from the plots. The $1/N^2$ contribution to this term can be easily obtained from second-order perturbation theory, as was done for bosons in [28], but the asymptotic nature of this expansion makes this calculation not very useful.
Off-diagonal correlations in 1D anyonic models

Figure 3. Off-diagonal correlation function for $\kappa = 0.5$ and $N = 101$. Top panels: real (left) and imaginary (right) parts of $\rho_{101}^{0.5}(t)$. Second rows: $\rho_{101}^{0.5}(t)/\rho_{FH}(t) - 1$. Third rows: subtraction of the first two harmonic terms $b_{\pm 1}$. Fourth rows: further subtraction of the analytic contributions $d_1$ (right) and $a_1, c_1$ (left). Bottommost panels: further subtraction of the analytic corrections $d_2$ (left) $a_1$ and $c_1$ (right).

8. The general anyonic Calogero–Sutherland model

The Hamiltonian of the Calogero–Sutherland model is given by a long-range pair interactions controlled by the coupling parameter $\lambda$:
\[
H = -\sum_{i=1}^{N} \frac{\partial^2}{\partial x_i^2} + \lambda(\lambda - 1) \sum_{i \neq j} \frac{\pi^2/L^2}{\sin^2(\pi(x_i - x_j)/L)}.
\]

The ground-state wavefunction of the Hamiltonian (52) was found in [43] and can be written in the form (3) with $f(y) = |y|^\lambda$, with normalization constant
\[
C_N^2(\lambda) = \frac{1}{L^N} \frac{\Gamma(1 + \lambda)^N}{\Gamma(1 + \lambda N)}.
\]

This model has always been considered only in the case of bosonic and fermionic statistics, or in the anyonic ones arising from having an analytic ground-state function, which implies $\kappa = \lambda$. While thermodynamic properties and diagonal correlations do not depend on $\kappa$, but only on $\lambda$, off-diagonal ones are a signature of the anyonic statistics and we can consider general $\kappa \neq \lambda$ as pointed out by Girardeau [7]. The off-diagonal correlators are easily obtained with the same replica trick as before.

doi:10.1088/1742-5468/2009/03/P03002
The one-body density matrix \( t = 2\pi x/L \) for \( N + 1 \) particles in a ring is
\[
g_1(x) = \frac{\Gamma(\lambda)\Gamma(1 + \lambda N)}{2\pi\Gamma(\lambda(1 + N))} \left( \prod_{j=1}^{N} B_\kappa(t - \theta_j) |1 - e^{i\theta_j}|^\lambda \right) |e^{it} - e^{i\theta_j}|^\lambda\right), \tag{54}
\]
where the average is defined as
\[
\langle f(e^{i\theta_1}, \ldots, e^{i\theta_N}) \rangle_{N,\lambda} = \frac{\Gamma^N(1 + \lambda)}{\Gamma(1 + \lambda N)} \int_0^{2\pi} d^{N} \theta \frac{\Delta_{N}(\{e^{i\theta_i}\})}{(2\pi)^N} \left( \frac{2}{\lambda} \right)^{2\lambda} f(e^{i\theta_1}, \ldots, e^{i\theta_N}),
\]
and \( \Delta_N(\{z_i\}) \) is the usual Vandermonde determinant.

To calculate the average in (54) we use the replica trick, along the lines of the calculation in [27] and [28], modified to include the anyonic statistics. Namely, consider the function
\[
Z_{2np}^{(\lambda)}(t) = \left( \prod_{j=1}^{N} (1 - e^{i\theta_j})^{2np}(e^{it} - e^{i\theta_j})^{2np} \right)_{N,\lambda}, \tag{55}
\]
but now the replica limit is \( 2np \to \lambda \). The duality transformation [34], which enables us to re-express the \( N \)-dimensional integral (55) depending on the parameter \( 2np \) as a \( 2np \)-dimensional integral depending on \( \lambda \) as a parameter, is the same as for bosons [30]:
\[
Z_{2np}^{(\lambda)}(t) = \frac{e^{-iN np t}}{S_{2np}(1/\lambda)} \int_0^1 d^{2np} x |\Delta_{2np}(\{x_a\})|^{(2/\lambda)} \prod_{a=1}^{2np} [x_a(1 - x_a)]^{1/(\lambda) - 1} [1 - (1 - e^{it})x_a]^N. \tag{56}
\]

**Figure 4.** As figure 3 but with \( \kappa = 0.9 \) and \( N = 121 \).
The duality $\lambda \leftrightarrow 1/\lambda$ becomes evident by comparing the powers of Vandermonde determinants in the previous equations. We put $Z_{2np}^{(\lambda)}(0) = 1$, so the normalization constant is given by the Selberg integral

$$S_{2np}(1/\lambda) = \int_0^1 d^{2np}x \ |\Delta_{2np}(x)|^{(2/\lambda)} \prod_{a=1}^{2np} x_a^{(1/\lambda)-1} (1 - x_a)^{(1/\lambda)-1}$$

$$= \prod_{a=1}^{2np} \Gamma^2 (a/\lambda) \Gamma (1 + (a/\lambda)) \Gamma ((2np + a)/\lambda).$$

One can perform the sum over the saddle points at $x_{\pm} = 0, 1$ arriving at the same form as before:

$$Z_{2np}(t) = \sum_{l=0}^{2np} (-1)^{2np/\lambda(np-l)} \frac{H_{2np}^l(\lambda)e^{\pi(t+(2np/\lambda)(np-l))}}{(2\pi)^{(l^2+(2np-l)^2)/\lambda}},$$

but with a $\lambda$ dependent $H_{2np}^l(\lambda)$ factor given for integer $2np = m$ in [30] as

$$H_{m}^l(\lambda) = \frac{\Gamma(m+1)}{\Gamma(l+1)\Gamma(m-l+1)} \frac{I_l(\lambda)I_{m-l}(\lambda)}{S_m(1/\lambda)},$$

with $S_m(1/\lambda)$ given above and $I_l(\lambda) = (\prod_{a=1}^l \Gamma(a/\lambda)\Gamma[1+a/\lambda])/\Gamma[1+1/\lambda]^l$.

After trivial algebra we get

$$H_{m}^l(\lambda) = \prod_{c=1}^m \frac{\Gamma((m+c)/\lambda)}{\Gamma(c/\lambda)} \left( \prod_{l=1}^m \frac{\Gamma(a/\lambda)}{\Gamma((m-l+a)/\lambda)} \right)^2.$$ (59)

For $\lambda = 1$ this formula reduces to equation (25) whose analytic continuation to complex $n$ can be written in terms of Barnes $G$-functions. Unfortunately this is not possible for general $\lambda$ (special formulae can be found for integer $\lambda$ or $1/\lambda$, but they are not very illuminating). Not having this nice representation in terms of special functions, the analytic continuation becomes less simple, but still straightforward, and it is reported in the appendix.

The anyonic statistics is obtained by setting $np - l = nq - m$ and so

$$g_\kappa^m(x) = \sum_{m=-\infty}^{\infty} (-1)^{(\kappa/2+m)} H_{1/2+\kappa/2-m}(\lambda) e^{\pi(x(\kappa+2m)(N+1)/L)}$$

$$\frac{(N + 2m(N+1)/L)}{(2N \sin \pi x/L)^{(\lambda/2+2(m+\kappa/2)^2)/\lambda}},$$

where $H_{1/2+\kappa/2-m}(\lambda)$ is intended to be continued as explained in the appendix.

Explicitly we get

$$\rho_{\infty} = \frac{(-1)^{\kappa/2}}{(2\lambda/2+\kappa/2)(2\lambda)} H_{\lambda-\kappa/2}^{\lambda}(\lambda-\kappa/2),$$

$$b_{m+1} = - \left[ \frac{\Gamma((1/2) + (\kappa/2\lambda) + ((m + 1)/2\lambda))}{\Gamma((1/2) - (\kappa/2\lambda) - (m/2\lambda))} \right]^{2} 2^{2(2m+2\kappa+1)/\lambda},$$

and $b_0 = 1$. This expression agrees with the general harmonic expansion (34) with $K = \lambda^{-1}$ as is well known (the parameter $K$ does not depend on the statistic $\kappa$ and so it is the same as that derived by Ha [44] for $\kappa = \lambda$). In figure 5 we report the

doi:10.1088/1742-5468/2009/03/P03002
correlations obtained by summing a few of the first terms in the harmonic expansion for several values of the anyonic parameter $\kappa$ at fixed $\lambda$ to show the crossover from the fermionic to the bosonic curves. The extreme results $\kappa = 0, 1$ were already determined in [30] (small manipulations are needed to show that they are identical), where a perfect agreement with quantum Monte Carlo simulations has been shown.

This harmonic expansion has been previously calculated in specific cases (bosons and fermions for generic $\lambda$ in [30] and for $\kappa = \lambda$ in [44]). It requires a long, but simple calculation to show that all these expansions agree. Other exact results appear in [45]–[49], [38, 50, 51] also for dynamical correlation functions.

9. Conclusions

In this work we proposed a variation of the replica method that allows the calculation of the large distance asymptotics of off-diagonal correlation functions in anyonic models. The main result that we found is that the replicated correlation $Z_{2np}(t)$ is a function with $2p$ branches corresponding to different anyon statistics $\kappa = q/p$ with $q = 0, \ldots, 2p - 1$. 

doi:10.1088/1742-5468/2009/03/P03002
After having understood this, it is almost straightforward, but tedious, to obtain all the harmonic terms of the large distance expansion from known results for bosons. We applied the method to a gas of impenetrable anyons (the Tonks–Girardeau case) and the most general anyonic Calogero–Sutherland form. For the former a number of analytic and numerical checks confirmed the validity of the replica approach. For the latter however, for special values of the interaction parameters (i.e. integer or rational), a number of exact results have been already found thanks to the random matrix theory and its connection with Jack polynomials [46]–[48], [44, 49, 38]. In some cases the correspondence of the two approaches is obvious, while in some others (for rational $\lambda = p/q$ the correlation functions are given by sums over fractional excitations involving $p+q$ quantum numbers, giving an irregular function of $\lambda$ with no clear limit to irrational values) it implies particular relations for Jack polynomials. Showing this correspondence in full generality remains an open problem.

At the same time, another open problem is the correspondence of our approach to the one given by Patu et al [22], based on Fredholm determinants. We stress that (as far as we are aware) the explicit correspondence of the two approaches has not yet been proved even for bosons. The results coming for these two sets of works give an almost complete physical picture of the behavior of the off-diagonal correlator of the gas of impenetrable anyons. Beyond the impenetrable limit, only the Bethe solution of the Lieb–Liniger model is known [4, 5], with still no attempt to tackle the hard problem of the correlation functions exactly. Only the power-law structure (and the corresponding singularities) are known from bosonization [11, 12]. A powerful approach would be to generalize the quantum inverse scattering methods for bosons [52] to anyons and then to mix integrability and numerics to get the full correlation functions from the form factors (along the lines of [53] for bosons).

Acknowledgments

We thank G Marmorini, S Ouvry, V Pasquier, E Tomni, and P Wiegmann for useful discussions. This work was done in part when the authors were guests of the Galileo Galilei Institute in Florence, whose hospitality is gratefully acknowledged. Financial support from the ESF (INSTANS activity) is also acknowledged.

Appendix. The analytic continuation

We need to analytically continue terms of the form

$$h^l_m = \prod_{a=1}^{l} \frac{\Gamma(a/\lambda)}{\Gamma((m-l+a)/\lambda)}.$$  

Using the integral representation of the log of the Gamma function

$$\log\Gamma(z) = \int_0^{\infty} \frac{dt}{t} \left( \frac{e^{-zt} - e^{-t}}{1 - e^{-t}} + (z-1)e^{-t} \right);$$

summing the resulting geometrical series and changing the integration variable, we have

$$\log h^l_m = \int_0^{\infty} \frac{dt}{t} e^{-t} \left[ \frac{1 - e^{-ul} - e^{-t(m-l)} + e^{-mt}}{(1 - e^{-t})(1 - e^{-\lambda t})} - \frac{(m-l)t}{\lambda} e^{-(\lambda-1)t} \right].$$

\[A.3\]
For the first harmonic and any $\kappa$ and $\lambda$, the single terms in the integral all diverge; only their sum is finite. The integral is an analytic function of $l$ and $m$ and can then be used to evaluate $h_m^l$ for any complex $m, l$ for the first harmonic. The others are obtained from the recurrence relation in the text.

For the coefficients $H_m^l(\lambda)$ in the text we also need the analytic continuations of $f_m = \Gamma((m+c)/\lambda)/\Gamma(c/\lambda)$ which are very similar:

$$\log f_m = -\int_0^\infty \frac{dt}{t} e^{-t} \left[ \frac{(1 - e^{-mt})^2}{(1 - e^{-t})(1 - e^{-\lambda t})} - \frac{m}{\lambda} e^{-(\lambda-1)t} \right],$$

(A.4)

which is vanishing for $\lambda = 1$ and $m \to 1$ as it should be. Plugging everything together,

$$\log H_m^l(\lambda) = 2 \log h_m^l + \log f_m.$$  

(A.5)

Note added. After the completion of this work, a work appeared where some large distance asymptotics of the off-diagonal correlations for the Tonks–Girardeau gas have been found at finite temperature [54]. The results obtained there are different and complementary to ours. Notice that the integral system of partial differential equations that they derive is independent of the anyonic parameter $\kappa$ that enters only through the initial condition, along the lines of our previous [21] and current results.
