Farmers' Response on Field Performance of BSMRAU Developed IPSA Seem and BU Pepe1 Crop Variety

Md. Safiul Islam Afrad, Md. Amzad Hossain, Md. Enamul Haque, Md. Azizul Hoque, Shahriar Hasan, Soumitra Saha, and Muhammad Ziaul Hoque

ABSTRACT

The study was conducted to investigate the adoption of IPSA seem and BU pepe1 crop variety by the farmers in Bhaluka upazila of Mymensingh and Meherpur Sadar upazila of Meherpur districts, respectively in Bangladesh. In-person interviews with 80 respondents and two focus group discussions were carried out to collect data. According to study findings, the highest portion of the respondents were young aged, literate, had medium farm size, low farming experience, and organizational participation and their average annual income were Tk. 192850 and Tk. 200500 for IPSA seem and BU pepe1 growers, respectively. Extent of adoption was above fifty percent in both cases of IPSA seem and BU pepe1 whereas the extent of BU pepe1 adoption was higher than IPSA seem. Performance of IPSA seem and BU pepe1 was satisfactory to the farmers in terms of ease of handling, better marketability and adaptation to the environment, vigor, and better physical appearance. Majority of the IPSA seem and BU pepe1 respondents experienced a medium increase in crop yield while medium to high-income increase by cultivating those varieties. Majority of them had a low to moderate knowledge gap in cultivating IPSA seem and BU pepe1. The major problems faced by the farmers were pod borer infestation, common mosaic virus for IPSA seem while low germination percentage, common mosaic virus for BU pepe1. The study results showed that respondents with small farm sizes were more interested in adopting IPSA seem than others. So, engaging small farmers in cultivating IPSA seem would make this technology more available and popular among the farmers.

Keywords: Adoption, BSMRAU, BU pepe1, IPSA seem, Performance.

I. INTRODUCTION

Agriculture is not only the subject matter of supplying food for a family but also a business. Previously, agriculture was known as the production of crops and collection of year-round food. But now the agricultural problems are becoming more complex that hamper overall crop production. To keep human life running it is necessary to increase agricultural production. Along with the increased production of grain crops, high-yielding fruits and vegetables can play a vital role in meeting the nutritional demand of Bangladesh [1], [2].

According to [3], the general recommendation for intake of fruits and vegetables is at least 400 grams per person per day. The people of Bangladesh consume a total of 126g of fruit and vegetables daily which is far below the minimum daily requirement. That’s why the cultivation of high-yielding crop varieties is very important to ensure the demand for food and nutrition [2], [4]. In Bangladesh, fruit production increased from 1357.0 thousand metric tons in 1970-71 to 5018.0 thousand metric tons in 2016-17 [5]. Vegetable production also increased by 2.5 times. Ensuring food security has been one of the major goals of Bangladesh since its independence in 1971 when most of the people were living under the poverty line [6]. Adoption of high-yielding crop varieties by farmers is a solution to food insecurity [7]-[10]. The prevalent factor in enhancement in yield is stimulated by
high-yielding varieties (HYV), irrigation, fertilizer, and other management technology [11]-[15].

Population pressure continues to place a severe burden on productive capacity [16]. Food demand is growing over time due to rapid population growth and in some cases income growth, placing pressure on agricultural production in developing countries [17], especially in Bangladesh [18]. To meet this demand, the use of improved agricultural technologies can enhance productivity [8], [19]. The growth of agriculture will depend more and more on yield-increasing technological change [20]. According to [21] and [22], improving the livelihoods of rural farm households through agricultural productivity in developing countries would remain an undiluted wish if the agricultural technology adoption rate is low. Hence, there is a need to adopt the proven agricultural technologies to flourish production as well as productivity and thereby the living condition of the rural poor [23].

Technological innovation is one of the major factors shaping agriculture, and it, along with institutional changes, not only shapes and improves the agricultural sector, but reduces poverty, and improves standards of living through increased productivity [24], [25]. Problems of poverty and food security that are rampant in rural communities can be reduced through improved agricultural productivity which is a very important method [26].

Though many modern technologies have been adopted in the agriculture sector of Bangladesh, still they are very insufficient as well as unfamiliar to the farmers [27]. Different research organizations are also developing new technologies to make agriculture more profitable. Among them, BARI, BRRI, BJRI, BTRI, BAU, BSMRAU, SAU are well known. Bangabandhu Sheikh Mujibur Rahman Agricultural University (BSMRAU) is one of the organizations that are working relentlessly in this regard. BSMRAU has been conducting basic and applied research since its inception as IPSA (Institute of Post Graduate Studies in Agriculture) to generate appropriate and sustainable technologies in the field of agriculture as well as disseminate and transfer generated technologies to the end-users through training and outreach program [19], [28]. BSMRAU released technologies are adapting with different climate stress condition, accepting by the farmers, and contributing to national food security, poverty reduction, and sustainable agro-rural development [19].

So far, BSMRAU has released 52 different crop varieties [29]. Among them, IPSA seem and BU pepe1 are renowned varieties adopted by the farmers in different agro-ecological areas. BU pepe1 was released in 2012 and its salient features are high yielding, gynoecioecious, produces 98.0% female plant, an oval-shaped, reddish color with a sweet taste and high market price. Another popular technology developed by BSMRAU (former IPSA) IPSA seem that was released in 1991. Its main features are high yielding, earlier maturity, more seeds, less disease infestation, low requirement of fertilizer, etc. [29]. But there is a dearth of information regarding the adoption level of these two crop varieties in farmers’ conditions. The present study, therefore, investigated to assess the adoption of IPSA seem and BU pepe1 in the farmers’ field, their performance, obstacles, and prospects.

II. METHODOLOGY

A. Locale of the Study

Though BSMRAU developed technologies have been cultivating in different agro-ecological zones of Bangladesh, Meherpur Sadar Upazila was selected for IPSA seem while for BU pepe1, Bhaluka Upazila of Mymensingh was selected. The study locations were selected purposively because each of the specific BSMRAU technology has been adopted by the farmers of that areas.

B. Population and Sampling

IPSA seem and BU pepe1 growers of the study sites were the target population of the present study. Lists of heads of all IPSA seem and BU pepe1 households of the selected areas were collected from the concerned Upazila Agriculture Extension Offices and Sub Assistant Agriculture Officers (SAAOs). From the collected lists, 40 farmers were selected randomly as a sample for each of BSMRAU technology. Thus, a total of 80 (40 individuals from each proposed study area) respondents were selected following a simple random sampling method.

C. Data Collection Methods

For the study, data were collected from the respondents...
through a face-to-face interview. All possible precautions were taken to avert bias and to maintain the fidelity of the responses. Statements were recorded what respondents said, not made judgments or comments on them. The objectives of the study were explained to them. At the time of the interview, the researcher asked each question steadily and whenever it was felt necessary. The questions were explained and clarified whenever any respondent felt difficulty in understanding. Two Focus Group Discussions (FGDs) were conducted in two locations for the collection of qualitative information to validate the findings.

D. Performance of IPSA Seem and BU pepe1 in Farmer’s Field

The performance of IPSA seem and BU pepe1 was measured in respondents’ response percent on some selected characteristics which are relative advantage, compatibility, complexity, trial-ability, and observability. Here increased income, better marketability, ease of handling, the better taste was the scale of relative advantages following social compatibility, adoption to the environment, input requirement, and personal compatibility for the compatibility. Additional requirement of input, handling difficulty, complicated to understand were the parameters for the measurement of complexity following more time, input, the cost required for trial-ability. Observability was measured by the vigor and better physical appearance. Impact of performance was measured by percentage yield increase and percent income increase.

E. Extent of Adoption

A new technology adoption can be measured in different ways. [30] has constructed a multidimensional adoption scale to measure the rate of adoption of new technology. The scale covers both duration as well as area dimensions under the use of the particular practice under measurement. The formula constructed by [30] to compute the Adoption Quotient (AQ) for an individual has been adapted to express the AQ in percent (multiplying the AQ by 100). The AQ can range from 0 to 100, where 0 (zero) indicates no adoption of the practice and 100 indicates full adoption. The modified formula for calculating the AQ is presented below.

\[ AQ = \frac{T_1 \times T_2 \times A_2}{T_3 \times A_1} \times 100 \]

where,

- AQ = Adoption Quotient;
- \( T_1 \) = Year since the practice under study was introduced;
- \( T_2 \) = Year since the user became aware of the practice;
- \( T_3 \) = Year since the practice was adopted by the user;
- \( A_1 \) = Potential area (acre/ha) under the practice during the surveyed year;
- \( A_2 \) = Actual area (acre/ha) under the practice during the surveyed year.

The extent of adoption of those technologies were measured from the above formula.

F. Duration of Usage and Impact of a Technology

The duration of usage of IPSA seem and BU pepe1 was measured by counting the years of practicing the technologies. A score of one (1) was assigned to each year. Usage of IPSA seem and BU pepe1 was measured by computing the score of the respondents.

The advantage of innovation to the economy and production is the impact of technology. Increment of the total production was computed and also estimated total increased revenue of the technology. The lifestyle and socio-economic condition of a community can be upgraded through new technology. Therefore, the annual earning increment is one of the signs of a good technology as a positive impact.

G. Knowledge Gap

Farmers’ agricultural knowledge referred to the understanding and acquaintance with different agriculture-related activities. To assess the respondent’s knowledge gap on different practices, fifteen questions were asked with two marks allotted for each. Total marks obtained by a respondent were added to evaluate their knowledge level. For a correct answer, a respondent was given two marks, and for a partial answer one mark. In case of an incorrect answer, a score of ‘0’ was given. Knowledge gap was calculated by subtraction of obtained individual’s marks from the total marks. Based on mean and standard deviation knowledge gap was categorized into the following:

| Categories | Score  |
|------------|--------|
| Low        | up to 9 |
| Moderate   | 9-16   |
| High       | above 16 |

The respondents were asked about the problems which they faced while using the BSMRAU technologies. Respondents were also asked about the probable suggestions against each of the problems. The major problems they faced and offered suggestions were listed and ranked based on frequency.

H. Processing and Analysis of Data

After completion of the survey, all interview schedules were accumulated, and local units were converted into a standard unit. Appropriate scoring technique was followed to convert the qualitative data into quantitative data. All the collected data were classified, coded, compiled, and tabulated for processing and analysis following the objectives of the study. The SPSS/PC + statitix10 was used to perform the data analysis. [13] used a similar method for analyzing the data. Data were presented mostly in tabular forms, statistical measures like number, range, mean, and percentage for describing the data. Linear regressions were computed to indicate the contribution of selected characteristics of the respondents towards their adoption of IPSA seem and BU pepe1.

III. RESULTS AND DISCUSSIONS

A. Farmers’ Socio-demography

The distribution of respondents (farmers) based on their socio-demographic characteristics has been shown in Table II. The age category showed that mainly young-aged farmers were involved in IPSA seem (57.5%) and BU pepe1 (45.5%) cultivation. Sixty percent (60%) of the IPSA seem respondents were literate, and it was 57.5 percent for BU
pepe1. Most of the IPSA seem respondents (62.5%) belonged to medium family-size while most of BU pepe1 respondents (47.5%) belonged to small family size. Most of the IPSA seem (75%), and BU pepe1 (67.5%) respondents possessed medium to large farm size. The average income of IPSA seem (BDT 192850), and BU pepe1 (BDT 200500) respondents were much higher than the national average (BDT 149518) [31]. In both cases, most of the farmers had low to medium farming experience. Data on training experience indicated that a portion of IPSA seem (42.5%) and BU pepe1 (37.5%) received training from NGOs and local agriculture office, and most of them received training of fewer than 2 days. Most percentages of the IPSA seem respondents (75%) maintained contact with SAAOs while most of BU pepe1 respondents (62.5%) kept a connection with friends/ family/relatives. The highest portion of the respondents (65% for IPSA seem and 82.5% for BU pepe1) had no organizational participation.

### TABLE II: SOCIO-DEMOGRAPHIC FEATURES OF THE RESPONDENTS

| Characteristics | Categories | Respondents | Mean |
|-----------------|------------|-------------|------|
| Age (year)      | Young (<35) | 23          | 18.4 |
|                 | Middle (36-50) | 17          | 12.5 |
|                 | Old (>50)   | 13          | 32.5 |
| Education (year) | Illiterate (0) | 16          | 40.0 |
|                 | Primary (1-5) | 05          | 12.5 |
|                 | Secondary (6-10) | 15          | 37.5 |
|                 | Higher secondary (>10) | 04          | 10.0 |
| Farm Size (Person) | Small (<4) | 11          | 27.5 |
|                 | Medium (4-6) | 25          | 62.5 |
|                 | Large (>6)  | 04          | 10.0 |
| Farm Size (Hectare) | Small (up to 1.00) | 10          | 22.5 |
|                 | Medium (1.01-3.00) | 26          | 65.0 |
|                 | Large (Above 3.00) | 04          | 10.0 |
| Annual Income (BDT) | Low (up to Tk. 150,000) | 19          | 47.5 |
|                 | Medium (Tk. 150,000-300,000) | 18          | 45.0 |
|                 | High (Above Tk. 300,000) | 03          | 07.5 |
| Farming Experience (Year) | Low (up to 16) | 23          | 57.5 |
|                 | Medium (16-35) | 14          | 35.0 |
|                 | High (Above 36) | 03          | 07.5 |
| Training Experience (Day) | NGOs | 05          | 12.5 |
|                 | Upazila Agriculture Office | 12          | 30.0 |
|                 | No training | 23          | 57.5 |
| Training duration | Up to 2 days | 10          | 25.0 |
|                 | 3 to 4 days | 05          | 12.5 |
|                 | 5 days and above | 02          | 5.0 |
|                 | No training received | 23          | 57.5 |
| Information Source | NGO | 06          | 15.0 |
|                 | AEO | 17          | 42.5 |
|                 | SAAO | 30          | 75.0 |
|                 | Friends/family/relative | 17          | 42.5 |
|                 | Fellow farmers | 12          | 30.0 |
| Organizational participation | No member | 26          | 65.0 |
|                 | Member | 14          | 35.0 |

B. Performance of the IPSA Seem and BU pepe1

As stated by the highest portion of the respondents, both technologies had better marketability, ease of handling, and better taste. Most of them observed that both technologies were socially acceptable, adaptable with the environment, and personally compatible. The respondents perceived less complexity and trialability when they cultivated BU pepe1. Most percentages of them noticed vigor and better physical appearance in both technologies (Table III).

From this table, it is clear that BU pepe1 exhibited comparatively better performance than IPSA seem. Better performance of any technologies stimulates farmers to adopt it more rapidly and to a large extent. Similar findings are reflected in the study of [32], where increased family income, decent profitability, increased social reputation, better compatibility with the environment made BARI cowpeal popular among farmers and positively influenced its adoption rate. Simultaneously, [33] witnessed a moderate to high adoption rate of BRRI dhan28 in coastal areas of Bangladesh due to its high market return, less-complex cultivation technique, high social acceptance, high yield, good trialability (short duration variety), the good physical appearance of grains, and good compatibility with the coastal environment.

C. Usages, Extent of Adoption, and Impact of Technology

Results presented in Table IV indicate that most of the IPSA seem respondents (42.5%) practiced it for 4 to 6 years while major portion BU pepe1 respondents (87.5%) practiced it for up to 3 years. The extent of adoption of BU pepe1 (60%) was higher than IPSA seem (52.7%). Most of the IPSA seem (45%), and BU pepe1 (67.5%) respondents experienced medium yield increment by utilizing the two technologies.
However, most percentages of IPSA seem (75%), and BU pepel (85%) respondents experienced medium to high-income increase by utilizing them.

| TABLE III: PERFORMANCE OF BSMRAU DEVELOPED TECHNOLOGIES (IPSA SEEM, BU PEPEL) |
|---------------------------------|-------------------|-------------------|
| Perceived attributes | Indicators | Respondents (%) |
| Relative advantage | 1. Increased income | 15.40 | 18.00 |
| | 2. Better marketability | 75.60 | 81.30 |
| | 3. Ease of handling | 78.50 | 77.30 |
| | 4. Better taste | 77.6 | 86.00 |
| Compatibility | 1. Social acceptability | 82.20 | 83.10 |
| | 2. Adaptation to environment | 85.50 | 86.50 |
| | 3. Additional input requirement | 1.00 | 3.00 |
| | 4. Personal compatibility | 77.50 | 76.00 |
| Complexity | 1. Handling difficulty | 12.40 | 18.30 |
| | 2. Complicated to understand | 10.00 | 13.10 |
| Trial ability | 1. More time requirement | 1.20 | 2.60 |
| | 2. More input requirement | 04.50 | 04.80 |
| | 3. More cost involvement | 04.50 | 05.10 |
| Observability | 1. Vigor | 75.00 | 77.80 |
| | 2. Better physical appearance | 81.00 | 85.00 |

BU pepel was a newly introduced variety in the study area; that’s why its duration of usage ranged up to 6 years. In contrast, IPSA seem was an older variety and had been cultivating for more than 6 years.

High extent of adoption was observed in BU pepel. It might be due to BU pepel showed better performance over IPSA seem in terms of relative advantage, compatibility, complexity, trialability, and observability. As BU pepel was a new variety, the extension personnel provided the respondents with better information regarding its cultivation which positively influenced its extent of adoption. [9] also observed high adoption of BARI-recommended potato varieties among farmers as proper extension services from GOs and NGOs increased their skills and knowledge of that technologies. Though the initiation of IPSA seems was not new but its expansion was not satisfactory. A similar scenario has been reflected in the study of [33] in BRRI dhan28.

Respondents’ knowledge regarding proper crop management ensured the satisfactory yield of both varieties. As a result, a significant portion of the respondents experienced a medium to high-income increase after adopting those technologies. A study by [34] on BINA masur5 also noticed similar findings where farmers received a high return from it as they followed proper crop management guidelines during cultivation.

D. Knowledge Gap

An assessment of the respondents’ technical knowledge regarding IPSA seems and BU pepel production has been presented in Table V. On average, respondents of both technologies exhibited a medium knowledge gap (mean score 11.8 and 12.0 for IPSA seem and BU pepel, respectively). Most of the IPSA seem (85.0%), and BU pepel (87.5%) growers possessed low to a medium level knowledge gap on the cultivation technique of two technologies. The respondents possessed considerable knowledge on the farming of improved varieties. It might be due to a portion of them had agricultural training experience from whom other non-trained fellow workers got suggestions. Furthermore, they regularly kept contact with extension personnel of both GOs and NGOs for improved farming tips. This knowledge motivated the farmers to adopt modern technologies. [33] also noticed that sound knowledge of the farmers on rice cultivation techniques inspired them to adopt BRRI dhan28 to a large extent.

| TABLE IV: USES, EXTENT OF ADOPTION, AND IMPACT OF BSMRAU TECHNOLOGIES |
|-----------------|-----------------|-----------------|
| Attributes | Categories | Respondents (%) |
| Duration of usage | Up to 3 years | 40.0 | 87.5 |
| | 4-6 years | 42.5 | 12.5 |
| | Above 6 years | 17.5 | 0.0 |
| Extent of adoption | Low (up to 10%) | 45.0 | 32.5 |
| | Medium (11-20%) | 45.0 | 67.5 |
| | High (above 20%) | 10.0 | 0.0 |
| Yield increase | Low (up to 3%) | 25.0 | 15.0 |
| | Medium (4-6%) | 37.5 | 47.5 |
| | High (above 6%) | 37.5 | 37.5 |

E. Constraints and Suggestions

The respondents were asked to mention the problems they encountered while practicing the technologies and requested to opine suggestions on minimizing the problems. Results presented in Table VI represent the information on constraints and suggestions from the respondents of both varieties.

In the IPSA seem, pod borer infestation was recognized as a key problem faced by 78.0 percent of the respondents followed by a common mosaic virus attack (70%). In contrast, most percentage (82%) of BU pepel growers faced poor seed germination followed by the attack of common mosaic virus (75%).

To combat the problems, the highest portion (84%) of the IPSA seem growers suggested the development of pest-resistant variety followed by providing training to the farmers (76%). However, most of the BU pepel growers (80%) recommended a variety with high germination percentage followed by the development of virus-resistant variety (78%) and providing training facilities to farmers (55%).

From these findings, it is evident that respondents of both technologies acutely suffered from pest attack and sought pest-resistant varieties. Adoptability of crops is negatively affected by frequent pest infestation which has also been reflected in the study of [32], [35]-[37]. Hence, researchers should emphasize this issue to make varieties less pest vulnerable.

Technical skill about improved production technology is very much vital for effective use of inputs and getting the desired yield. Lack of training acts as a barrier to obtain a high yield from improved varieties. Therefore, respondents of both varieties suggested hands-on training on those varieties’ production. These findings are in line with the study of [37]. Simultaneously, in a study of [32] on BARI mung, farmers suggested to arrange training for them to combat pest problems more efficiently.

F. Findings of Qualitative Study

Two Focus Group Discussions (FGDs) were carried out in two locations to explore the salient features of IPSA seem and BU pepel. A total of 30 farmers (15 individuals from each technology user respondents) were selected as participants. It
so was ensured that all of them willingly joined, and local leaders acted as moderators during the discussion sessions. Findings gathered from the focus group discussion have been presented in Box I.

### TABLE V: Respondents’ Knowledge Gap on IPSA Seem and BU Pepe1 Cultivation

| Knowledge                          | Respondents (IPSA seem) | Respondents (BU pepe1) |
|------------------------------------|-------------------------|------------------------|
| Frequency                          | Percent                 | Frequency              | Percent |
| Low (up to 9)                      | 22.5                    | 16                     | 40.0    |
| Medium (9-16)                      | 62.5                    | 11.8                   | 47.5    | 12.0  |
| High (above 16)                    | 15.0                    | 5                      | 12.5    |

### TABLE VI: Identified Problems and Offered Suggestions from Respondents for Both BSMRAU Technologies

| Innovation | Respondent | Problems                      | % | Rank | Suggestion                    | % | Rank |
|------------|------------|-------------------------------|---|------|-------------------------------|---|------|
| IPSA seem  |            | Pod borer infestation        | 78.0 | 1st  | Insect and disease resistant variety | 84.0 | 1st |
|            |            | Common mosaic virus          | 70.0 | 2nd  | Training facilities           | 76.0 | 2nd |
|            |            | Wither away of flowers       | 50.0 | 3rd  | Increase taste                | 52.0 | 3rd |
|            |            | Thickening of stem           | 42.0 | 4th  |                                |     |      |
| BU pepe1   |            | Low germination percentage   | 82.0 | 1st  | Increase germination percentage | 80.0 | 1st |
|            |            | Common mosaic virus          | 75.0 | 2nd  | Virus resistant variety       | 78.0 | 2nd |
|            |            | Less compactness             | 57.0 | 3rd  | Arrangement of training       | 55.0 | 3rd |
|            |            | Lower taste                  | 30.0 | 4th  | More availability of seed     | 37.0 | 4th |

### TABLE VII: Contribution of Selected Socio-economic Characteristics of the Respondents to Their Adoption of IPSA Seem and BU pepe1

| Variables | Respondents of IPSA seem | Respondents of BU pepe1 |
|-----------|--------------------------|-------------------------|
|           | β | P value | β | P value |
| Age       | 0.168 | 0.75 | 0.32 | 0.08 |
| Educational level | -0.42 | 0.65 | -0.88 | 0.29 |
| Family size | 1.47 | 0.65 | 0.07 | 0.96 |
| Farm size | -2.62 | 0.01 | -0.018 | 0.96 |
| Total income | 2.74 | 0.92 | 0.12 | 0.43 |

### BOX I: Salient Features of BSMRAU Technology [Based on FGD, N=30 (15+15)]

| Salient features of IPSA seem | Salient features of BU pepe1 |
|-----------------------------|-------------------------------|
| Whitish green               | Reddish flesh                |
| Better yield                | Sweet taste                  |
| More seed                   | High market price            |
| Less disease infestation    | Very poor seed               |
| Collar rot                  | germination rate             |
|                            | Gap inflorescence            |

In the case of IPSA seem, respondents were satisfied with its better yield and seed production capability. Though it was comparatively more disease resistant than other varieties, respondents were a bit concerned about the collar rot problem. In comparison, sweet taste and high market price were the remarkable features of BU pepe1. But poor seed germination and the gap in inflorescence curtailed its popularity among growers. The FGDs finally concluded that identified characteristics of the two technologies were acceptable for adoption in the study areas.

Generally, the drivers intensely influenced farmers’ adoption decisions about any technology were yield performance and profitability, biotic and abiotic stress tolerant capability, availability of good quality seeds, quality of crop product, and market demand [36], [38]. In most cases, better yield acts as a chief driving force behind adopting any technology because high yield ensures high returns and ultimately reduces poverty among farmers [39].

### G. Contribution of Selected Socio-economic Characteristics to the Adoption of IPSA Seem and BU pepe1

This section explores the contribution of selected characteristics of the respondents towards their adoption of IPSA seem and BU pepe1 as presented in Table VII. Regression results indicated that nine variables together explain 43.21 percent variation in the adoption of IPSA seem. Out of nine characteristics, only farm size showed a negative significant contribution towards the adoption of IPSA seem. It means that small farmers were interested in the adoption of IPSA seem. This might be because of their direct contact with the farming operations and the adoption of new technologies as their own choice. Similar findings were observed by [35] on the adoption of mango variety. They found that farm size had a negative significant effect on the adoption level of BARI mango3 variety because large farmers had more options to choose other mango varieties. [36] also found that increase in farm size caused less adoption of BRRI rice varieties as larger farms choose more yielders like hybrid rice or Indian varieties and high-value rice like aromatic variety for high profitability. According to the study by [33], farm size had a negative and significant relationship with the adoption of BRRI dhan28. Contrarily, [38] and [40] observed reverse findings in their study that said an increase in farm size increased the probability of farmers adopting and intensifying the BRRI rice varieties. But findings of [9] were slightly different where education and knowledge regarding BARI potato varieties positively contributed to its adoption.
In the same way, [41] noticed that educational level, annual family income, extension media contact influenced the adoption of BRRI than49 by the farmers. On the other hand, nine variables together explain 28.72 percent variation in the adoption of BU pepe1. But none of the nine socioeconomic characteristics of the respondents showed significant contribution towards the adoption of BU pepe1.

IV. CONCLUSION

Majority of the farmers (IPSA seem 57.5% and BU pepe1 45%) were young aged and literate (IPSA seem 60% BU pepe1 57.5%) with low to medium farm size (IPSA seem 90% BU pepe1 82.5%) having low farm experience (IPSA seem 57.5% BU pepe1 65%). Low organizational participation (IPSA seem 35% BU pepe1 17.5%) was found with an average annual income of Tk. 192850 and Tk. 200500 in case of IPSA seem and BU pepe1. Extent of adoption of BU pepe1 (60%) was higher than IPSA seem (52.7%). Majority (IPSA seem 78.5% and BU pepe1 77.3%) of the farmers found ease of handling and better marketability (IPSA seem 75.6%, BU pepe1 81.3%), better adaptation to the environment (85.5%, BU pepe1 86.5%), and improved physical appearance (IPSA seem 81.0%, BU pepe1 85.0%). Most of them (IPSA seem 45.0%, BU pepe1 67.5%) experienced a medium yield increase. Most percentages of them (IPSA seem 75%, BU pepe1 85%) experienced medium to high-income increase. A vital portion of the farmers (IPSA seem 85% and BU pepe1 87.5%) had a low to medium level knowledge gap in the cultivation of these two crops. Major problems faced by the farmers were poor pest infestation, common mosaic virus for IPSA seem and low germination percentage, common mosaic virus for BU pepe1. Important suggestions for improvement of IPSA seem were the development of insect and disease resistant variety and arrangement of training facilities while increase germination percentage and virus-resistant variety were for BU pepe1. Farm size was the only contributing factor that influenced their adoption of IPSA seem. That means the smaller the farm size of the farmers, the higher their adoption of IPSA seem.

APPENDIX

Abreviations:
AEO: Agriculture Extension Officer
AQ: Adoption Quotient
BARI: Bangladesh Agricultural Research Institute
BAU: Bangladesh Agricultural University
