Fast algorithms for general spin systems on bipartite expanders

April 29, 2020

Abstract

A spin system is a framework in which the vertices of a graph are assigned spins from a finite set. The interactions between neighbouring spins give rise to weights, so a spin assignment can also be viewed as a weighted graph homomorphism. The problem of approximating the partition function (the aggregate weight of spin assignments) or of sampling from the resulting probability distribution is typically intractable for general graphs.

In this work, we consider arbitrary spin systems on bipartite expander $\Delta$-regular graphs, including the canonical class of bipartite random $\Delta$-regular graphs. We develop fast approximate sampling and counting algorithms for general spin systems whenever the degree and the spectral gap of the graph are sufficiently large. Our approach generalises the techniques of Jenseen et al. and Chen et al. by showing that typical configurations on bipartite expanders correspond to “bicliques” of the spin system; then, using suitable polymer models, we show how to sample such configurations and approximate the partition function in $\tilde{O}(n^2)$ time, where $n$ is the size of the graph.

*Authors’ address: Department of Computer Science, University of Oxford, Wolfson Building, Parks Road, Oxford, OX1 3QD, UK.
1 Introduction

Spin systems are general frameworks that encompass sampling and counting problems in computer science, graph homomorphism problems in combinatorics, and phase transition phenomena in statistical physics. In this paper, we provide algorithms for general spin systems on bounded-degree bipartite expander graphs.

A $q$-spin system is specified by a set of spins $[q] = \{1, 2, \ldots, q\}$ and a symmetric interaction matrix $H \in \mathbb{R}_{\geq 0}^{q \times q}$. Given a graph $G = (V_G, E_G)$, a spin configuration is an assignment $\sigma : V_G \to [q]$ and the weight of $\sigma$ is given by $w_{G,H}(\sigma) = \prod_{\{u,v\} \in E_G} H_{\sigma(u),\sigma(v)}$. The Gibbs distribution of the system, denoted by $\mu_{G,H}$, is a probability distribution on the set $\Sigma_{G,H}$ which denotes the set of all possible spin configurations, given by

$$\mu_{G,H}(\sigma) = \frac{w_{G,H}(\sigma)}{Z_{G,H}},$$

where $Z_{G,H} := \sum_{\sigma \in \Sigma_{G,H}} w_{G,H}(\sigma)$ is the so-called partition function. Well-known examples of spin systems are the Ising/Potts models, where the matrix $H$ has all diagonal entries equal to some parameter $\beta > 0$ and off-diagonal entries equal to 1; the case $q = 2$ is the Ising model, and $q > 2$ is the Potts model. Apart from statistical physics systems, graph homomorphisms also fit naturally into this framework, whenever $H$ has 0-1 entries.

Henceforth, we will normalise $H$ so that its largest entry is equal to 1. More formally, we will consider $\delta$-matrices, defined as follows.

**Definition 1.** Let $q \geq 2$ and let $\delta \in (0, 1)$. A symmetric matrix $H \in \mathbb{R}_{\geq 0}^{q \times q}$ is called a $\delta$-matrix if $\max_{i,j \in [q]} H_{i,j} = 1$ and $\max_{i,j \in [q]} H_{i,j} \neq 1$.

Note that, apart from trivial cases\(^1\), we can always normalise the interaction matrix of a spin system to satisfy Definition 1 for some $\delta \in (0, 1)$.

Approximately sampling from the Gibbs distribution of a spin system and approximating its partition function are well-studied problems in computer science, since they appear in various applications. However, even for the most canonical models, such as the Potts model or graph homomorphisms, these computational problems are hard in general, even on bounded-degree graphs \([9, 3, 16, 15, 11, 14, 13]\).

In light of these hardness results, it is natural to consider whether efficient algorithms can be developed for more restricted classes of graphs. Recently, Jenssen, Keevash, and Perkins \([21]\) (see also \([19]\)) showed a new framework that such algorithms are possible for three canonical models (ferromagnetic Potts model, colourings, and independent sets) on bounded-degree expander graphs, in a range of parameters where the problems are otherwise hard for general bounded-degree graphs. In this paper, we show that this framework can further be used to obtain approximation algorithms of any spin system on bipartite expander graphs whenever the degree is sufficiently large.

More precisely, we will consider regular bipartite graphs whose second eigenvalue is bounded by a small constant \([20]\). Let $G$ be an $n$-vertex $\Delta$-regular bipartite graph. Let $\lambda_1(G) \geq...
\[ \lambda_2(G) \geq \cdots \geq \lambda_n(G) \] denote the eigenvalues of the adjacency matrix of \( G \). It is well-known that \( \lambda_1(G) = \Delta \) and \( \lambda_n(G) = -\lambda_1(G) \). We define \( \lambda(G) = \lambda_2(G) \).

**Definition 2.** Let \( \Delta \geq 3 \) be an integer and \( \lambda \) be a positive real strictly less than \( \Delta \). We let \( \mathcal{G}^{\text{bip}}_{\Delta, \lambda} \) denote the set of all connected \( \Delta \)-regular bipartite graphs \( G \), for which \( \lambda(G) \leq \lambda \). \( \square \)

One of the primary examples of bipartite expander graphs, and one of the main motivations behind this work, are random bipartite regular graphs. It is known [2] that, for any fixed \( \varepsilon > 0 \), with high probability\(^2\) over the choice of a random bipartite \( \Delta \)-regular graph \( G \), it holds that \( \lambda(G) \leq 2\sqrt{n-1} + \varepsilon \). From a counting/sampling perspective these graphs are particularly interesting since they have been key ingredients in obtaining inapproximability results [24, 4, 12]. Somewhat surprisingly, while we know constant factor estimates of the partition function via (non-algorithmic) probabilistic methods that hold with probability \( 1 - o(1) \) over the choice of the graph [12], it is not known how to approximately sample from the Gibbs distribution efficiently. In fact, even obtaining more refined estimates on the partition function is an open problem. As a corollary of our main result, we address both of these questions, provided that the degree \( \Delta \) is sufficiently large relative to \( \lambda \).

To formally state our results, we will need some definitions. First, the following computational problem that we will study.

**Parameters:** \( H \), a symmetric matrix in \( \mathbb{R}^{q \times q}_{\geq 0} \), integer \( \Delta \geq 3 \), and a real \( \lambda \in (0, \Delta) \).

**Name:** \( \text{SPIN}_{H, \Delta, \lambda} \).

**Input:** A graph \( G \in \mathcal{G}^{\text{bip}}_{\Delta, \lambda} \).

**Output:** The value of \( Z_{G,H} \).

In particular, we consider the problem of approximating \( Z_{G,H} \) and sampling from \( \mu_{G,H} \). Given an accuracy parameter \( \varepsilon > 0 \), we say that \( \hat{Z} \) is an \( \varepsilon \)-approximation to \( Z \) if \( (1 - \varepsilon)Z \leq \hat{Z} \leq (1 + \varepsilon)Z \). For a distribution \( \mu \), we say that a random variable \( X \) is an \( \varepsilon \)-sample from \( \mu \) if the total variation distance between the distribution of \( X \) and \( \mu \) is at most \( \varepsilon \). A fully polynomial randomised approximation scheme (FPRAS) for \( \text{SPIN}_{H, \Delta, \lambda} \) is a randomised algorithm that, given \( \varepsilon > 0 \) and \( G = (V, E) \in \mathcal{G}^{\text{bip}}_{\Delta, \lambda} \) as input, outputs a random variable that is an \( \varepsilon \)-approximation to \( Z_{G,H} \) with probability at least \( 3/4 \), in time \( \text{poly}(|V|, 1/\varepsilon) \).\(^3\)

We prove the following result. For a bipartite graph \( G \), we use \((V^0_G, V^1_G)\) to denote the bipartition of the vertex set of \( G \), and all logarithms throughout the paper are with base \( e \).

**Theorem 3.** Let \( q \geq 2 \) be an integer, \( \delta \) be a real in \((0,1)\), \( H \in \mathbb{R}^{q \times q}_{\geq 0} \) be a symmetric \( \delta \)-matrix. Suppose that \( \Delta, \lambda \) satisfy \( \frac{\Delta}{\lambda} \geq \frac{100}{1-3}q^2 \log(q\Delta) \) and \( \Delta \geq \left( \frac{10}{1-3}q \log(q\Delta) \right)^4 \). Then, there is an FPRAS for \( \text{SPIN}_{H, \Delta, \lambda} \).

In fact, there is a randomised algorithm that, given a graph \( G \in \mathcal{G}^{\text{bip}}_{\Delta, \lambda} \) with \( n = |V^0_G| = |V^1_G| \) vertices and an accuracy parameter \( \varepsilon^* \geq e^{-n/(5\delta)} \), outputs an \( \varepsilon^* \)-approximation to \( Z_{G,H} \) and an \( \varepsilon^* \)-sample from the Gibbs distribution \( \mu_{G,H} \) in time \( O((n/\varepsilon^*)^2 \log^3(n/\varepsilon^*)) \).

As a corollary of Theorem 3, we have the following for random bipartite \( \Delta \)-regular graphs.

\(^2\)Here and throughout the paper, “with high probability” means with probability tending to 1 as the size of the graph tends to infinity.

\(^3\)Note, the error probability can be reduced to any \( \eta > 0 \) by calling the original FPRAS \( O(\log(1/\eta)) \) times.
Corollary 4. Let \( q \geq 2 \) be an integer, \( \delta \) be a real in \((0,1)\), and \( H \in \mathbb{R}_{\geq 0}^{q \times q} \) be a symmetric \( \delta \)-matrix. Then, for all integers \( \Delta \geq \left( \frac{10}{\log(qq)} \log(q\Delta) \right)^4 \), there is a randomised algorithm such that the following holds with high probability over the choice of a random \( \Delta \)-regular bipartite graph \( G \) with \( n = |V^0_G| = |V^1_G| \).

The algorithm, on input \( G \) and an accuracy parameter \( \varepsilon^* \geq e^{-n/(5q)} \), outputs in time \( O((n/\varepsilon^*)^2 \log^3(n/\varepsilon^*)) \) an \( \varepsilon^* \)-approximation to the partition function \( Z_{G,H} \) and an \( \varepsilon^* \)-sample from the Gibbs distribution \( \mu_{G,H} \).

Proof. Using the result in \([2, \text{Theorem 4}]\), we have that, with high probability over the choice of \( G \), it holds that \( \lambda(G) \leq 2\sqrt{\Delta} \). It follows that \( \frac{\lambda}{\lambda(G)} \geq \frac{1}{2}\sqrt{\Delta} \) and hence the result follows by applying Theorem 3.

1.1 Proof Outline

In order to prove our main Theorem 3, we appeal to what are known as polymer models, as introduced by Gruber and Kunz \([17]\) in the statistical physics literature. Recently, polymer models have been used as a tool in the development of efficient counting and sampling algorithms \([19, 21, 1, 23, 7, 5, 6]\) for problems that are not amenable to traditional approaches such as local-update Markov chains. Our approach is inspired by, and generalises, the approaches in \([21, 7]\), where counting and sampling algorithms are given for the hard-core and ferromagnetic Potts models on expander graphs at low temperatures.

The main idea behind the use of polymer models is that, for graphs with good expansion properties, the partition function and the Gibbs distribution are dominated by configurations which are highly ordered, i.e., whose weight is large. As we shall see in detail in Section 3, these large-weight configurations correspond to “bicliques” of \( H \), as defined below.\(^4\)

Definition 5. Let \( q \geq 2 \) be an integer, \( \delta \in [0,1) \) be a real and \( H \in \mathbb{R}_{\geq 0}^{q \times q} \) be a symmetric \( \delta \)-matrix. A biclique of \( H \) is a pair \((B_0,B_1)\) with \( B_0,B_1 \subseteq [q] \), such that \( H_{i,j} = 1 \) for all \( i \in B_0 \) and all \( j \in B_1 \). We use \( K_H \) to denote the set of all bicliques of \( H \) and we use \( K^\text{max}_H \) to denote the set of all inclusion maximal bicliques of \( H \).

Note that, for a bipartite graph \( G \), configurations \( \sigma \) which assign vertices in \( V^0_G \) a spin from \( B_0 \) and vertices in \( V^1_G \) a spin from \( B_1 \) have weight 1, the largest possible weight (since \( H \) is a \( \delta \)-matrix). Polymer models allow us to capture deviations from such configurations and approximate their contribution to the partition function, see Section 4.

Using the results of Sections 3 and 4, we give the proof of Theorem 3 in Section 5.

2 Preliminaries

Let \( G \) be a bipartite graph. We will write \( G \) as \((V^0_G,V^1_G,E_G)\), where \((V^0_G,V^1_G)\) denotes the bipartition of the vertex set of \( G \) and \( E_G \) its edge set; we will use \( V_G = V^0_G \cup V^1_G \) to denote the vertex set of \( G \).

For a vertex subset \( S \subseteq V_G \), let \( \partial_G S \) denote the set of vertices of \( V_G \setminus S \) that have a neighbour in \( S \), and let \( S^\pm = S \cup \partial_G S \). When \( S = \{u\} \), we simply write \( \partial_G u \) instead of \( \partial_G S \). For vertex subsets \( S,T \subseteq V_G \), let \( E_G(S,T) \) denote the set of edges of \( G \) that have one

---

\(^4\)The “biclique” terminology comes from the homomorphism problem (where \( H \) corresponds to a graph), but our interpretation here is analogous which justifies its use.
endpoint in \( S \) and the other in \( T \), and let \( e_G(S, T) = |E_G(S, T)| \); when \( S = T \), we simply write \( E_G(S), \sigma_G(S) \) instead of \( E_G(S, S), \sigma_G(S, S) \), respectively. We will omit \( G \) from all of the above notation where it is obvious from the context.

### 2.1 Bipartite Expander Graphs

It is well-known that graphs in \( \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) have good expansion properties, and in this section we will review certain edge and vertex expansion properties that will be relevant for us.

The following result relates the spectrum of a regular bipartite graph to its edge-expansion properties. This result was first proven in [18, Theorem 5.1], though the version we state below is taken from [8].

**Lemma 6** ([8, Lemma 8]). Let \( G = (V_G^0, V_G^1, E_G) \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) with \( n = |V_G^0| = |V_G^1| \). Then, for sets \( S_0 \subseteq V_G^0, S_1 \subseteq V_G^1 \), we have that

\[
|e_G(S_0, S_1) - \frac{\Delta|S_0||S_1|}{n}| \leq \lambda \sqrt{|S_0||S_1|} \left( 1 - \frac{|S_0|}{n} \right) \left( 1 - \frac{|S_1|}{n} \right).
\]

The following simple consequence of the above result gives a lower bound on the edge expansion of \( G \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) when \( \lambda \) is sufficiently small.

**Corollary 7.** Let \( G = (V_G^0, V_G^1, E_G) \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) with \( n = |V_G^0| = |V_G^1| \). Then, for sets \( S_0 \subseteq V_G^0, S_1 \subseteq V_G^1 \) such that \( \lambda \leq \frac{1}{2n} \sqrt{|S_0||S_1|} \), it holds that \( e_G(S_0, S_1) \geq \frac{\Delta}{2n}|S_0||S_1| \).

**Proof.** Lemma 6 implies that

\[
|e_G(S_0, S_1) - \frac{\Delta|S_0||S_1|}{n}| \leq \frac{\Delta|S_0||S_1|}{2n}, \quad \text{therefore } e_G(S_0, S_1) \geq \frac{\Delta|S_0||S_1|}{2n}.
\]

A second combinatorial notion of expansion is vertex expansion. A well-known result from Tanner [25] relates the spectrum of a graph to its vertex expansion properties (see also [22] for a more refined estimate). Here we state a version from [20, Theorem 4.15]: there, the result is stated and proved for non-bipartite graphs, but a minor adaption of the proof in [20], which we give for completeness here, also applies to bipartite graphs.

**Lemma 8.** Let \( G = (V_G^0, V_G^1, E_G) \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}}, \rho > 0 \) be a real number and \( i \in \{0, 1\} \). Then, for all \( S \subseteq V_G^i \) with \( |S| \leq \rho|V_G^i| \), it holds that \( |\partial S| \geq |S|/(\rho + \frac{\lambda^2}{\Delta^2}(1 - \rho)) \).

**Proof.** We prove the result for \( i = 0 \); the case \( i = 1 \) is symmetric. Let \( S \subseteq V_G^0 \) be such that \( |S| \leq \rho n \) where \( n = |V_G^0| = |V_G^1| \). We will show that \( |\partial S| \geq |S|/(\rho + \frac{\lambda^2}{\Delta^2}(1 - \rho)) \).

Let \( A = A_G \) denote the adjacency matrix of \( G \), and \( B \) be the bi-adjacency matrix of \( G \), so that \( A = \begin{bmatrix} 0 & B \\ B^T & 0 \end{bmatrix} \). Then, we have that \( \mu \) is an eigenvalue of \( A \) if and only if \( \mu^2 \) is an eigenvalue of \( BB^T \). Let \( v_1, \ldots, v_n \) be orthonormal eigenvectors of \( BB^T \), with eigenvalues \( \lambda_1^2, \ldots, \lambda_n^2 \), where \( \lambda_1, \ldots, \lambda_n \) are the eigenvalues of \( A \) in decreasing order. Note that \( \lambda_1^2 = \Delta^2, \lambda_2^2 = \lambda^2 \) and since \( G \) is \( \Delta \)-regular, we have that \( v_1 = \frac{1}{\sqrt{n}} e_1 \), where \( e_1 \) is the \( n \)-dimensional vector with all ones.

From the spectral theorem, we have the decomposition

\[
BB^T = \sum_{i \in [n]} \lambda_i^2 v_i v_i^T.
\]
We define \( \Sigma \) configurations

Definition 9. Let \( Z \) be the symmetric \( \delta \) integers and \( \lambda, \delta \) sufficiently large relative to \( \varepsilon \), \( \varepsilon \) be the configurations which are “close to maximal bicliques”, cf. Definition 1.

Lemma 10. Let \( \varepsilon \) be sufficiently large relative to \( \lambda, \Delta, q \), \( \varepsilon \) be the configurations which are “close to maximal bicliques”, cf. Definition 1.

The following result shows that \( \Sigma \) configurations which are “close” to some maximal bicliques, namely, in the proof of Theorem 3.

Combining (2) and (3) yields the desired inequality.

\[ ||1^T S B||^2 = 1^T S B B^T 1S = \sum_{i \in [n]} \lambda_i^2 \alpha_i^2 \leq \Delta^2 \alpha_1^2 + \lambda^2 (|S| - \alpha_1^2) \leq |S| (\Delta^2 \rho + \lambda^2 (1 - \rho)). \] (2)

For \( j \in [n] \), let \( u_j \) be the \( j \)-th entry in \( 1^T S B \); observe that \( u_j \) is the number of neighbours in \( S \) of the \( j \)-th vertex in \( V^1_G \) and hence there are exactly \( |\partial S| \) non-zero entries in \( 1^T S B \). Moreover, since \( G \) is \( \Delta \)-regular, we have that \( \sum_{j \in \partial S} u_j = \sum_{j \in [n]} u_j = 1^T S B e_1 = \Delta |S| \). From the Cauchy–Schwarz inequality, it follows that

\[ ||1^T S B||^2 \geq \sum_{j \in [n]} u_j^2 = \sum_{j \in \partial S} u_j^2 \geq \frac{1}{|\partial S|} \left( \sum_{j \in \partial S} u_j \right)^2 = \frac{1}{|\partial S|} \left( \sum_{j \in [n]} u_j \right)^2 = \Delta^2 |S|^2 / |\partial S|. \] (3)

Combining (2) and (3) yields the desired inequality.

\[ \square \]

3 Ground states for spin configurations

In this section, we show that the partition function of a spin system is dominated by configurations which are “close to maximal bicliques”, cf. Definition 5. Let \( q \geq 2, \Delta \geq 3 \) be integers and \( \lambda, \delta \) be reals with \( \lambda \in (0, \Delta) \) and \( \delta \in (0, 1) \). Let \( G \in G_{\Delta, \lambda}^{\text{bip}} \) and let \( H \in \mathbb{R}^{q \times q}_{\geq 0} \) be a symmetric \( \delta \)-matrix.

We next describe more precisely the configurations which are “close” to some maximal biclique of \( H \). Given \( \sigma : V_G \rightarrow [q] \) and a spin \( i \in [q] \), we write \( \sigma^{-1}(i) \) for the set of vertices of \( G \) whose image under \( \sigma \) is \( i \). More generally, for a subset of spins \( Q \subseteq [q] \), we let \( \sigma^{-1}(Q) = \{ v \in V_G : \sigma(v) \in Q \} \).

Definition 9. Let \( \varepsilon \in (0, 1) \). For \( (B_0, B_1) \in K^{\text{max}}_H \), define \( \Sigma_{G,H,\varepsilon}^{B_0,B_1} \) to be the set of spin configurations \( \sigma \in \Sigma_{G,H} \) for which

\[ |\sigma^{-1}(B_0) \cap V_G^0| + |\sigma^{-1}(B_1) \cap V_G^1| \geq (1 - \varepsilon)|V_G|. \]

We define \( \Sigma_{G,H,\varepsilon} \) to be the union of the sets \( \Sigma_{G,H,\varepsilon}^{B_0,B_1} \) over all bicliques \( (B_0, B_1) \in K^{\text{max}}_H \) and define \( Z_{G,H,\varepsilon} := \sum_{\sigma \in \Sigma_{G,H,\varepsilon}} w_{G,H}(\sigma) \).

The following result shows that \( Z_{G,H,\varepsilon} \) gives a close approximation to \( Z_{G,H} \) whenever \( \varepsilon \) is sufficiently large relative to \( \lambda, \Delta, q \).

Lemma 10. Let \( \varepsilon \in (0, 1) \) be such that \( \varepsilon \geq 2q\lambda / \Delta \) and \( \varepsilon^2 \geq \frac{8q^2 \log q}{\Delta \log(1/\delta)} \). Then, for \( G \in G_{\Delta, \lambda}^{\text{bip}} \) with \( n = |V_G^0| = |V_G^1| \), we have that \( Z_{G,H,\varepsilon} \) is an \( \varepsilon^{-n} \)-approximation to \( Z_{G,H} \).

\[ ^5 \text{Note, in Lemma 10, as in other lemmas as well, our assumed inequalities for } \varepsilon \text{ impose some restrictions on } \Delta, \lambda, q \text{ to ensure that such an } \varepsilon \text{ exists. These restrictions will be carefully accounted for when we apply these lemmas; namely, in the proof of Theorem 3.} \]
Proof. We associate each spin configuration \( \sigma \in \Sigma_{G,H} \) with a pair of spin subsets \((B_0(\sigma), B_1(\sigma))\) by setting for \(i \in \{0, 1\}\)

\[
B_i(\sigma) = \left\{ j \in [q] : |\sigma^{-1}(j) \cap V_G^i| \geq \frac{\varepsilon n}{q} \right\}.
\]

Note that for \( \sigma \in \Sigma_{G,H} \), there are fewer than \( \varepsilon n \) vertices of \( V_G^0 \) which are not assigned spins from \( B_0(\sigma) \cup B_1(\sigma) \). Also note that, since \( \varepsilon \in (0, 1) \), we have that \( B_i(\sigma) \neq \emptyset \) for \(i \in \{0, 1\}\).

Fix arbitrary \( \sigma \in \Sigma_{G,H} \). We first show that

\[
\text{either } (B_0(\sigma), B_1(\sigma)) \in K_H \text{ or } w_{G,H}(\sigma) \leq \delta \Delta r^2 n/(2q^2),
\]

i.e., either \((B_0(\sigma), B_1(\sigma))\) is a biclique of \( H \) or \( \sigma \) has small weight. For \(i \in \{0, 1\}\), consider arbitrary \( j_i \in B_i(\sigma) \) and let \( S_i = \sigma^{-1}(j_i) \cap V_G^i \). Since \(|S_i| \geq \varepsilon n/q\), we have that \( \frac{\sqrt{2n} |S_0||S_1|}{q} \geq \Delta \varepsilon/(2q) \geq \lambda \), thus it follows from Corollary 7 that

\[
e(S_0, S_1) \geq \frac{\Delta |S_0||S_1|}{2n} \geq \Delta \varepsilon^2 n/(2q^2).
\]

It follows that, if \( H_{j_0,j_1} \leq \delta \), then \( w_{G,H}(\sigma) \leq \delta \Delta r^2 n/(2q^2) \); otherwise, \( H_{j_0,j_1} = 1 \). Since \( j_0, j_1 \) were arbitrary spins in \( B_0(\sigma), B_1(\sigma) \), respectively, we conclude (4).

Let \( \sigma \) be such that \((B_0(\sigma), B_1(\sigma)) \in K_H \). Then there exists \((B_0, B_1) \in K_{H}^{\max} \) such that \( B_i(\sigma) \subseteq B_i \) for \( i \in \{0, 1\} \). Moreover, for \(i \in \{0, 1\}\) and \( j \in [q] \setminus B_i \), we have that \(|\sigma^{-1}(j) \cap V_G^i| < \varepsilon n/q\) and therefore that \(|\sigma^{-1}(\{j\} \cup B_i) \cap V_G^i| < \varepsilon n\). Hence, we conclude that

\[
|\sigma^{-1}(B_0) \cap V_G^0| + |\sigma^{-1}(B_1) \cap V_G^1| \geq (1-\varepsilon)|V_G|.
\]

Combining this with (4), we obtain that for all \( \sigma \in \Sigma_{G,H} \setminus \Sigma_{G,H,\varepsilon} \) it holds that \( w_{G,H}(\sigma) \leq \delta \Delta r^2 n/(2q^2) \), and hence

\[
Z_{G,H} - Z_{G,H,\varepsilon} \leq \sum_{\sigma \in \Sigma_{G,H} \setminus \Sigma_{G,H,\varepsilon}} \delta \Delta r^2 q^2 n \leq q^{2n} \delta \Delta r^2 n \leq q^{-2n},
\]

where in the last inequality we used that \( \Delta \geq \frac{8q^2 \log(q)}{\varepsilon^2 \log(1/\delta)} \). The result follows since \( Z_{G,H} \geq 1 \); this bound can be seen by considering the configuration that maps \( V_G^0 \) to \( j_0 \) and \( V_G^1 \) to \( j_1 \), where \( j_0, j_1 \in [q] \) are such that \( H_{j_0,j_1} = 1 \). \( \square \)

For our approximation algorithms, it will be useful to consider the following quantities.

**Definition 11.** For \( \varepsilon \in (0, 1) \), let

\[
\hat{Z}_{G,H,\varepsilon} = \sum_{(B_0, B_1) \in K_{H}^{\max}} \sum_{\sigma \in \Sigma_{G,H}^{\mathtt{overlap}}} w_{G,H}(\sigma) \quad \text{and} \quad Z_{G,H,\varepsilon}^{\mathtt{overlap}} = \sum_{\sigma \in \Sigma_{G,H,\varepsilon}^{\mathtt{overlap}}} w_{G,H}(\sigma),
\]

where \( \Sigma_{G,H,\varepsilon}^{\mathtt{overlap}} := \bigcup_{(B_0, B_1) \in K_{H}^{\max}} \bigcup_{(C_0, C_1) \in K_{H}^{\max} \setminus \{(B_0, B_1)\}} \left( \Sigma_{G,H,\varepsilon} \inter \Sigma_{G,H,\varepsilon}^{\mathtt{overlap}} \right) \)

The following lemma shows, given a value of \( \varepsilon \) that is sufficiently small, that \( \hat{Z}_{G,H,3\varepsilon} \) is a close approximation to \( Z_{G,H,\varepsilon} \) by showing that \( Z_{G,H,3\varepsilon}^{\mathtt{overlap}} \) is small relative to \( Z_{G,H,\varepsilon} \).
Lemma 12. Let $\varepsilon \in (0, \frac{1}{24q \log q}]$ be such that $\varepsilon^2 \geq \frac{8q^2 \log(q)}{3 \log(1/q)}$ and $\varepsilon \geq 2q^{\frac{1}{2}}$. Then, for all $G \in \mathcal{G}^{\text{bip}}_{\lambda, \delta}$ with $n = |V_G| = |V_1|$ sufficiently large, we have that $Z_{G,H,3\varepsilon}^{\text{overlap}} \leq e^{-n/(3q)} Z_{G,H,\varepsilon}$ and that $\hat{Z}_{G,H,3\varepsilon}$ is an $e^{-n/(4q)}$-approximation to $Z_{G,H,\varepsilon}$.

Proof. We will show the result for all integers $n$ satisfying $n^2 26q \varepsilon^3 n/(3q) \leq e^{2n/(3q)} (1 - 2q/\varepsilon)^2$.

Since $\Sigma_{G,H,3\varepsilon} = \bigcup_{(B_0,B_1) \in \mathcal{K}_H^{\text{max}}} \Sigma_{G,H,3\varepsilon}$ and $\Sigma_{G,H,\varepsilon} \subseteq \Sigma_{G,H,3\varepsilon}$, we have

$$\hat{Z}_{G,H,3\varepsilon} \geq Z_{G,H,3\varepsilon} \geq Z_{G,H,\varepsilon}$$

Moreover, each $\sigma \in \Sigma_{G,H,3\varepsilon}$ is accounted for at most $|\mathcal{K}_H^{\text{max}}| \leq 2q$ times in $\hat{Z}_{G,H,3\varepsilon}$, therefore

$$\hat{Z}_{G,H,3\varepsilon} \leq 2^{2q} \hat{Z}_{G,H,3\varepsilon} + \sum_{\sigma \in \Sigma_{G,H,3\varepsilon}} w_{G,H}(\sigma).$$

Since $\Sigma_{G,H,\varepsilon} \subseteq \Sigma_{G,H,3\varepsilon}$, we therefore have that

$$\hat{Z}_{G,H,3\varepsilon} - Z_{G,H,\varepsilon} \leq 2^{2q} \hat{Z}_{G,H,3\varepsilon} + \sum_{\sigma \in \Sigma_{G,H,3\varepsilon} \setminus \Sigma_{G,H,\varepsilon}} w_{G,H}(\sigma) \leq 2^{2q} \hat{Z}_{G,H,3\varepsilon} + Z_{G,H} - Z_{G,H,\varepsilon} \leq 2^{2q} \hat{Z}_{G,H,3\varepsilon} + e^{-n} Z_{G,H,\varepsilon},$$

where the last inequality follows from Lemma 10. The lemma will thus follow by showing

$$2^{2q} \hat{Z}_{G,H,3\varepsilon} \leq e^{-n/(3q)} Z_{G,H,\varepsilon},$$

since then, from (5) and (6), we obtain that

$$\hat{Z}_{G,H,3\varepsilon} - Z_{G,H,\varepsilon} \leq (e^{-n} + e^{-n/(3q)}) \cdot Z_{G,H,\varepsilon} \leq e^{-n/(4q)} \cdot Z_{G,H,\varepsilon}.$$

It remains to prove (6). Consider $(B_0, B_1), (C_0, C_1) \in \mathcal{K}_H^{\text{max}}$ such that $(B_0, B_1) \neq (C_0, C_1)$ and let us upper bound the aggregate weight of configurations in the set $F := \Sigma_{G,H,3\varepsilon} \cap \Sigma_{G,H,3\varepsilon}$. In fact, we will just upper bound $|F|$ and use the trivial upper bound 1 on the weight of a configuration. For $\sigma \in F$, let $S = \bigcup_{i \in \{0,1\}} (V_G \setminus \sigma^{-1}(B_i))$ and $T = \bigcup_{i \in \{0,1\}} (V_G \setminus \sigma^{-1}(C_i))$, so that $|S|, |T| \leq 3\varepsilon |V_G| = 6n$. For $\varepsilon \in (0, 1/10)$, there are at most $\sum_{k=0}^{\lfloor 6n \rfloor} \binom{2n}{k} \leq n \left( \frac{2n}{10} \right)^k$ ways to choose each of $S$ and $T$, and then, crudely, $q^{12n}$ ways to assign them spins; further, for $i \in \{0,1\}$, the vertices in $V_G \setminus (S \cup T)$ can be coloured in at most $|B_i \cap C_i|^n$ ways, since they must have a colour in $B_i \cap C_i$. Observe now that at least one of the inequalities $|B_0 \cap C_0| \leq |B_0| - 1, |B_1 \cap C_1| \leq |B_1| - 1$ must hold since otherwise $B_0 \subseteq C_0, B_1 \subseteq C_1$, contradicting the maximality $(B_0, B_1) \in \mathcal{K}_H^{\text{max}}$. We also have the bounds

$$\left( \frac{|B_i| - 1}{|B_i|} \right)^n \leq (1 - 1/q)^n \leq e^{-n/q}$$

for $i \in \{0,1\}$.

Combining the above, we obtain

$$\sum_{\sigma \in \Sigma_{G,H,3\varepsilon} \cap \Sigma_{G,H,3\varepsilon}} w_{G,H}(\sigma) \leq n^2 \left( \frac{2n}{6n} \right)^2 q^{12n} e^{-n/q} |B_0|^n |B_1|^n.$$
We have $|K_H^{\max}| \leq 2^{2q}$ and $\binom{2n}{6en} \leq (e/3\varepsilon)^{6en}$, hence
\[ Z_{\text{overlap}}^{G,H,3\varepsilon} \leq n^{240} (eq/3\varepsilon)^{12en} e^{-n/q} \sum_{(B_0,B_1) \in K_H^{\max}} |B_0|^n |B_1|^n. \] (7)

For $c > 0$, the function $f(x) = (c/x)^x$ is increasing in the interval $(0, c/e]$, so using that $\varepsilon \leq \frac{1}{240 \log q}$, we further have that
\[ (eq/3\varepsilon)^x \leq (80eq^2 \log q)^{1/(240q \log q)} = e^{\frac{1+\log(80)+2 \log q + \log \log q}{240q \log q}} \leq e^{1/(20q)}, \] (8)
where in the last inequality we used that $\frac{1+\log(80)}{240q \log q} + \frac{1}{120q} \leq \frac{1}{20q}$. We also have the lower bound
\[ Z_{G,H,\varepsilon} \geq \left(1 - \frac{2q}{n}\right)^2 \sum_{(B_0,B_1) \in K_H^{\max}} |B_0|^n |B_1|^n \]
by considering the set of surjective maps from $V_G^\varepsilon$ to $B_0$ and from $V_G^\varepsilon$ to $B_1$ and applying the bound in [11, Lemma 17] (which is a simple corollary of an analogous bound in [10]). This, combined with (7), (8) and the choice of $n$, yields (6), finishing the proof of Lemma 12. \(\square\)

4 Using polymer models to estimate the partition function

In this section, we first define abstract polymer models, which will be important in obtaining our approximation algorithms, and then review the algorithmic results of [7] in Section 4.2. We then define a polymer model for spin systems in Section 4.3, and obtain approximation/sampling algorithms for it in Section 4.4.

4.1 Abstract polymer models

Our presentation of abstract polymer models follows mostly [21], but is slightly modified so that a polymer model is a function of both an underlying graph $G$ and a host graph $J_G$. This will be for convenience, since it allows algorithms that operate on polymer models to have access to both the underlying graph and the host graph (since it is possible that, in some polymer models, certain information about the structure of $G$ is lost when constructing $J_G$).

Let $G$ be a class of graphs. Given an underlying graph $G \in G$ and a set of spins $[q] = \{1, \ldots, q\}$, we construct a host graph $J_G$; in our case, we will set for example $G_J$ to be $G^3$ (see Section 4.3 for more details), but in general other choices are obviously possible. We assign to each vertex $v \in V_G$ a set of “ground state” spins $g_v \subseteq [q]$. A polymer is a pair $\gamma = (V_\gamma, \sigma_\gamma)$ consisting of a $J_G$-connected set of vertices $V_\gamma$ and an assignment $\sigma_\gamma : V_\gamma \rightarrow [q]$ such that $\sigma_\gamma(v) \in [q] \setminus g_v$ for all $v \in V_\gamma$. Let $P_G$ be the set of all polymers.

A polymer model for an underlying graph $G$ and host graph $J_G$ is defined by a set of allowed polymers $\mathcal{C}_G \subseteq P_G$, and a weight function $w_G : \mathcal{C}_G \rightarrow \mathbb{R}_{\geq 0}$. For polymers $\gamma, \gamma' \in P_G$, we write $\gamma \sim \gamma'$ to denote that $\gamma, \gamma'$ are compatible, i.e., if $d_{J_G}(V_\gamma, V_{\gamma'}) > 1$ where $d_{J_G}(\cdot, \cdot)$ denotes the graph distance in $J$. We define $\Omega_G = \{\Gamma \subseteq \mathcal{C}_G \mid \forall \gamma, \gamma' \in \Gamma, \gamma \sim \gamma'\}$ to be the set of all sets of mutually compatible polymers of $\mathcal{C}_G$; elements of $\Omega_G$ are called polymer configurations. The polymer model induces the partition function
\[ Z_G = \sum_{\Gamma \in \Omega_G} \prod_{\gamma \in \Gamma} w_G(\gamma), \]
where $\prod_{\gamma \in \emptyset} w_G(\gamma) = 1$, and the following Gibbs distribution on $\Omega_G$, defined by

$$
\mu_G(\Gamma) = \frac{\prod_{\gamma \in \Gamma} w_G(\gamma)}{Z_G},
$$

for all $\Gamma \in \Omega_G$. We use $(C_G, w_G, J_G)$ to denote the polymer model and $\{(C_G, w_G, J_G) \mid G \in \mathcal{G}\}$ to denote the family of polymer models corresponding to the class of graphs $\mathcal{G}$; we say that the family has degree bound $\Delta$ if, for every $G \in \mathcal{G}$, both $G$ and the host graph $J_G$ have maximum degree at most $\Delta$.

### 4.2 Algorithms for polymer models

Given a family of polymer models, Chen et. al. [7], building upon work of [21], give sufficient conditions under which the partition function of the polymer model can be efficiently approximated using Markov chains. We will briefly describe these conditions, as well as the key results from [7] that will be later important for us.

The first condition is known as computational feasibility and is defined as follows.

**Definition 13.** [7, Definition 3] Let $\mathcal{G}$ be a class of graphs. A family of polymer models $\{(C_G, w_G, J_G) \mid G \in \mathcal{G}\}$ is computationally feasible if, for all $G \in \mathcal{G}$ and all $\gamma \in \mathcal{P}_G$, we can determine whether $\gamma \in C_G$ and, if so, compute $w_G(\gamma)$ in time polynomial in $|V_\gamma|$.

The second condition is called the polymer sampling condition and is defined as follows.

**Definition 14.** [7, Definition 4] Let $q \geq 2, \Delta \geq 3$ be integers, and $\mathcal{G}$ be a class of graphs. A family of polymer models $\{(C_G, w_G, J_G) \mid G \in \mathcal{G}\}$ with $q$ spins and degree bound $\Delta$ satisfies the polymer sampling condition with constant $\tau \geq 5 + 3 \log((q - 1)\Delta)$ if $w_G(\gamma) \leq e^{-\tau|V_\gamma|}$ for all $\gamma \in C_G$ and all $G \in \mathcal{G}$.

The following result from [7] asserts that if a family of polymer models satisfies the above two conditions, then there are efficient approximation and sampling algorithms for the partition function and the Gibbs distribution of the polymer model, respectively.

**Theorem 15** ([7, Theorems 5 & 6]). Let $q \geq 2, \Delta \geq 3$ be integers, and $\mathcal{G}$ be a class of graphs. Suppose that $\{(C_G, w_G, J_G) \mid G \in \mathcal{G}\}$ is a family of computationally feasible polymer models with $q$ spins and degree bound $\Delta$ that satisfies the polymer sampling condition.

Then, there is a randomised algorithm that takes as input an $n$-vertex graph $G \in \mathcal{G}$ and an accuracy parameter $\varepsilon^* \in (0, 1)$ and outputs an $\varepsilon^*$-approximation to $Z_G$ in time

$$
O((n/\varepsilon^*)^2 \log^2(n/\varepsilon^*))
$$

with probability $\geq 3/4$. Moreover, there is a randomised algorithm that on input $G$ and $\varepsilon^*$ as before, outputs an $\varepsilon^*$-approximate sample from $\mu_G$ in time $O(n \log(n/\varepsilon^*))$.

### 4.3 Polymer model for spin systems

In this section we define a polymer model for spin systems that captures the deviations of spin configurations from maximal bicliques. The polymer model that we propose is a generalisation to arbitrary spin systems of a polymer model that was used in [21, Section 5] in the case of proper colourings.

Let $H \in \mathbb{R}^{q \times q}_{\geq 0}$ be a symmetric matrix and $(B_0, B_1) \in \mathcal{K}_H^{\text{max}}$ be a maximal biclique of $H$. Let $G \in \mathcal{G}^{\text{bip}}_{\Delta, \lambda}$ be a graph, and let $\varepsilon \in (0, 1)$. The host graph for the polymer model is
We let \( B \) and let \( \Omega \) weight of a polymer \( \gamma \) of polymer model \( \gamma \). Proof. Let \( \Omega \) denote the set of all polymers, i.e., all pairs \( \gamma = (V_\gamma, \sigma_\gamma) \) consisting of a \( G^3 \)-connected set of vertices \( V_\gamma \) and an assignment \( \sigma_\gamma : V_\gamma \to [q] \) such that \( \sigma_\gamma(v) \in [q] \setminus g_v \) for all \( v \in V_\gamma \). We define the set of allowed polymers as

\[
\mathcal{C}_{G,H,\varepsilon}^{B_0,B_1} = \left\{ \gamma \in \mathcal{P}_{G,H}^{B_0,B_1} : |V_\gamma| \leq \varepsilon |V_G| \right\} \tag{9}
\]

and let \( \Omega_{G,H,\varepsilon}^{B_0,B_1} \) denote the set of all sets of mutually compatible polymers. We define the weight of a polymer \( \gamma = (V_\gamma, \sigma_\gamma) \in \mathcal{C}_{G,H,\varepsilon}^{B_0,B_1} \) as

\[
w_{G,H}^{\gamma} = \frac{\prod_{\{u,v\} \in E_G(V_\gamma)} H_{\sigma_\gamma(u),\sigma_\gamma(v)} \prod_{u \in \partial V_\gamma} F_u}{\prod_{i \in \{0,1\}} |B_i|^{|V_G^i \cap V_\gamma^i|}}, \tag{10}
\]

where

\[
\text{for } u \in V_G^i \text{ with } i \in \{0,1\}, F_u := \sum_{j \in B_i} \prod_{v \in V_\gamma \cap \partial u} H_{j,\sigma_\gamma(v)}.
\]

We let \( Z_{G,H,\varepsilon}^{B_0,B_1} \) and \( \mu_{G,H,\varepsilon}^{B_0,B_1} \) denote the partition function and the Gibbs distribution of the polymer model \( \left( \mathcal{P}_{G,H,\varepsilon}^{B_0,B_1}, w_{G,H}^{\gamma} \right) \), as defined in Section 4.1.

The next lemma shows the motivation behind the definition of the weight of a polymer. For a polymer configuration \( \Gamma \in \Omega_{G,H,\varepsilon}^{B_0,B_1} \), let \( \Gamma = \bigcup_{\gamma \in \Gamma} V_\gamma \), and \( \sigma_\Gamma \) denote the assignment to vertices in \( \Gamma \) obtained by combining all of the assignments \( \sigma_\gamma \), for \( \gamma \in \Gamma \).

**Definition 16.** For \( \Gamma \in \Omega_{G,H,\varepsilon}^{B_0,B_1} \), define \( \Sigma_{G,H,\varepsilon}^{B_0,B_1}(\Gamma) \) to be the set of configurations \( \tau \) such that \( \tau|_{\Gamma} = \sigma_\Gamma \) and which map, for \( i \in \{0,1\} \), \( V_G^i \setminus (\cup \Gamma) \) to \( B_i \).

**Lemma 17.** Let \( n = |V_0^G| = |V_1^G| \). For all \( \varepsilon \in (0,1) \), and all polymer configurations \( \Gamma \in \Omega_{G,H,\varepsilon}^{B_0,B_1} \), we have that

\[
|B_0|^n |B_1|^n \prod_{\gamma \in \Gamma} w_{G,H}^{\gamma}(\gamma) = \sum_{\tau \in \Sigma_{G,H,\varepsilon}^{B_0,B_1}(\Gamma)} w_{G,H}(\tau).
\]

**Proof.** Let \( \gamma, \gamma' \) be two distinct polymers in \( \Gamma \). Since the polymers are compatible, they correspond to distinct \( G^3 \)-connected components; in particular, \( V_\gamma^+ \cap V_{\gamma'}^+ = \emptyset \). It follows that \( |(\cup \Gamma)^+| = \sum_{\gamma \in \Gamma} |V_\gamma^+| \). Hence, by the definition in (10), we have that

\[
|B_0|^n |B_1|^n \prod_{\gamma \in \Gamma} w_{G,H}^{\gamma}(\gamma) = |B_0|^n |B_1|^n \prod_{\gamma \in \Gamma} \frac{\prod_{\{u,v\} \in E_G(V_\gamma)} H_{\sigma_\gamma(u),\sigma_\gamma(v)} \prod_{u \in \partial V_\gamma} F_u}{\prod_{i \in \{0,1\}} |B_i|^{|V_G^i \cap V_\gamma^i|}} \prod_{i \in \{0,1\}} |B_i|^{|V_\gamma \setminus (\cup \Gamma)|} \prod_{\{u,v\} \in E_G((\cup \Gamma))} H_{\sigma_\Gamma(u),\sigma_\Gamma(v)} \prod_{u \in \partial((\cup \Gamma))} F_u. \tag{11}
\]

On the other hand, for each \( \tau \in \Sigma_{G,H,\varepsilon}^{B_0,B_1}(\Gamma) \), we have that

\[
w_{G,H}(\tau) = \prod_{\{u,v\} \in E_G((\cup \Gamma))} H_{\sigma_\Gamma(u),\sigma_\Gamma(v)} \prod_{u \in \partial((\cup \Gamma))} \prod_{v \in (\cup \Gamma) \cap \partial u} H_{\sigma_\Gamma(u),\tau(u)}.
\]
i.e., given \( \Gamma \) and that \( \tau \in \Sigma_{G,H}^{B_0,B_1}(\Gamma) \), the weight of \( \tau \) depends only on the assignment of \( \partial(\cup \Gamma) \).

Let \( W(\Gamma) \) be the set of configurations \( \eta : \partial(\Gamma) \to B_0 \cup B_1 \) such that vertices in \( \partial(\Gamma) \cap V_G^i \) take a spin in \( B_i \), for \( i \in \{0,1\} \). For \( \eta \in W(\Gamma) \), the number of configurations \( \tau \) in \( \Sigma_{G,H}^{B_0,B_1}(\Gamma) \) with \( \tau|_{\partial(\Gamma)} = \eta \) is \( \prod_{i \in \{0,1\}} |B_i| |V_G^i \setminus (\cup \Gamma)^+| \), and

\[
\sum_{\eta \in W(\Gamma)} \prod_{u \in \partial(\Gamma)} H_{\tau(u),\eta(u)} = \prod_{i \in \{0,1\}} \sum_{u \in V_G^i \cap \partial(\Gamma)} \sum_{\eta : \{u\} \to B_i \cap \partial(\Gamma)} H_{\tau(u),\eta(u)} = \prod_{u \in \partial(\Gamma)} F_u.
\]

It follows that

\[
\sum_{\tau \in \Sigma_{G,H}^{B_0,B_1}(\Gamma)} w_{G,H}(\tau) = \prod_{i \in \{0,1\}} |B_i| |V_G^i \setminus (\cup \Gamma)^+| \prod_{\{u,v\} \in E_G(V_T)} H_{\sigma_1(u),\sigma_2(v)} \prod_{u \in \partial(\Gamma)} F_u,
\]

which combined with (11) gives the desired equality. \( \square \)

The following quantity combines the partition functions of the polymer models corresponding to maximal bicliques of \( H \); we will use this as our approximation to \( Z_{G,H} \).

**Definition 18.** For \( \varepsilon \in (0,1) \), let

\[
Z_{G,H,\varepsilon}^{polymer} = \sum_{(B_0,B_1) \in K_H^{max}} |B_0|^n |B_1|^n \cdot Z_{G,H,\varepsilon}^{B_0,B_1}.
\]

The following lemma is a minor adaptation of [21, Claim 29] in our setting, and will be used to bound the aggregate size of polymer configurations.

**Lemma 19 ([21, Claim 29]).** Let \( \varepsilon \in (0,1) \) be such that \( \varepsilon \geq \lambda / \Delta \). Then, for \( G \in G_{\Delta,\lambda}^{bp} \) with \( n = |V_G^0| = |V_G^1| \) sufficiently large, there is no set \( S \subseteq V_G \) with \( |S| > 6en \) whose \( G^3 \)-connected components, say \( S_1, S_2, \ldots, S_k \), satisfy \( |S_i| \leq 2\varepsilon n \) for \( i \in [k] \).

**Proof.** We will show the result when \( n \geq 1/(2\varepsilon^2 \Delta) \). For the sake of contradiction, suppose that such a set \( S \) exists with \( |S| > 6en \) and whose \( G^3 \)-connected components \( S_1, S_2, \ldots, S_k \) satisfy \( |S_i| \leq 2\varepsilon n \) for \( i \in [k] \). Then, we can partition \( \{1,2,\ldots,k\} \) into sets \( T_1 \) and \( T_2 \) such that, for \( j \in \{1,2\} \), the set \( U_j = \cup_{i \in T_j} S_i \) satisfies \( |U_j| \geq 2\varepsilon n \). It follows by Corollary 7 that \( e_G(U_1, U_2) \geq 2\varepsilon^2 \Delta n \geq 1 \), therefore there must exist \( i \in T_1 \) and \( j \in T_2 \) such that \( e_G(S_i, S_j) \geq 1 \). This yields a contradiction since two distinct \( G^3 \)-connected components cannot be connected by an edge. \( \square \)

Finally, we have the following result.

**Lemma 20.** Let \( \varepsilon \in (0, \frac{1}{5(q \log q)} \) be such that \( \Delta \geq \frac{8q^2 \log(q)}{\varepsilon^2 q \log(1/\delta)} \) and \( \varepsilon \geq \frac{2q \Delta}{5} \). Then, for all \( G \in G_{\Delta,\lambda}^{bp} \) with \( n = |V_G^0| = |V_G^1| \) sufficiently large, we have that \( Z_{G,H,\varepsilon}^{polymer} \) is an \( e^{-n/(4q)} \) approximation to \( Z_{G,H,\varepsilon} \).

**Proof.** Using the definition of the polymer partition function \( Z_{G,H,\varepsilon}^{B_0,B_1} \) (see Section 4.3) and Lemma 17, we can rewrite \( Z_{G,H,\varepsilon}^{polymer} \) from Definition 18 as

\[
Z_{G,H,\varepsilon}^{polymer} = \sum_{(B_0,B_1) \in K_H^{max}} \sum_{\Gamma \in G_{\Delta,\lambda}^{bp}} |B_0|^n |B_1|^n \prod_{\gamma \in \Gamma} w_{G,H,\varepsilon}^{B_0,B_1}(\gamma)
= \sum_{(B_0,B_1) \in K_H^{max}} \sum_{\Gamma \in G_{\Delta,\lambda}^{bp}} \sum_{\sigma \in K_H^{max}(\Gamma)} w_{G,H}(\sigma).
\]
Recall from Definition 16 that $\Sigma_{G,H}^\Gamma$ is the set of configurations $\tau$ such that $\tau|_{\partial \Gamma} = \sigma_{\Gamma}$ and which map, for $i \in \{0, 1\}, V^i_G\setminus(\cup \Omega)$ to $B_i$. Recall also from Definition 9 that $\Sigma_{G,H,H}^B$ is the set of $\sigma \in \Sigma_{G,H}$ for which $|\sigma^{-1}(B_0) \cap V^0_G| + |\sigma^{-1}(B_1) \cap V^1_G| \geq (1 - \varepsilon)|V_G|$ and that $Z_{G,H,\varepsilon} := \sum_{\sigma \in \Sigma_{G,H,\varepsilon}} w_{G,H}(\sigma)$.

We first prove that $Z_{G,H,\varepsilon} \geq Z_{G,H,\varepsilon}$. Index the bicliques in $K_{G,\varepsilon}^\max$ arbitrarily. For $\tau \in \Sigma_{G,H,\varepsilon}$, let $(B_0, B_1)$ be the biclique $(B_0, B_1) \in K_{G,\varepsilon}^\max$ with the smallest index such that $\tau \in \Sigma_{G,H,\varepsilon}^B$. Let $T_i = V^i_G \setminus \hat{\tau}^{-1}([q] \setminus B_i)$ for $i \in \{0, 1\}$, so that $|T_0 \cup T_1| \leq \varepsilon|V_G|$. Let $S_1, \ldots, S_k$ denote the $G^3$-connected components of $T_0 \cup T_1$. Consider the polymer configuration $\Gamma_\tau$ which is the union of the polymers $(S_1, \tau|_{S_1}), \ldots, (S_k, \tau|_{S_k})$. Note that the map $\tau \mapsto (B_0, B_1, \tau, \Gamma_\tau)$ is injective. Moreover, we have that $\Gamma_\tau \in \Omega_{G,H,\varepsilon}^{B_0, B_1, \tau}$ and $\tau \in \Sigma_{G,H,\varepsilon}^{B_0, B_1, \tau}(\Gamma_\tau)$, so from (12) we obtain that $Z_{G,H,\varepsilon}^{\text{polymer}} \geq Z_{G,H,\varepsilon}$.

We next prove that $Z_{G,H,\varepsilon}^{\text{polymer}} \leq (1 + e^{-n/(4q)})Z_{G,H,\varepsilon}$. Recall from Definition 11 that

$$Z_{G,H,\varepsilon}^{\text{polymer}} = \sum_{(B_0, B_1) \in K_{G,H,\varepsilon}^\max} \sum_{\sigma \in \Sigma_{G,H,\varepsilon}^B} w_{G,H}(\sigma).$$

Fix any $(B_0, B_1) \in K_{G,H,\varepsilon}^\max$. For $\Gamma \in \Omega_{G,H,\varepsilon}^{B_0, B_1}$, we have from Lemma 19 that $|\| \leq 6\varepsilon n = 3\varepsilon|V_G|$. Therefore, for $\sigma \in \Sigma_{G,H,\varepsilon}^B(\Gamma)$ as in Definition 16, we have that $|\sigma^{-1}(B_0) \cap V^0_G| + |\sigma^{-1}(B_1) \cap V^1_G| \geq (1 - 3\varepsilon)|V_G|$ and hence $\sigma \in \Sigma_{G,H,\varepsilon}^{B_0, B_1, \tau}$ (cf. Definition 9). Note that the map $(\Gamma, \sigma) \mapsto \sigma$ is injective (since $\Gamma$ can be recovered from $\sigma$ using the biclique $(B_0, B_1)$), yielding that

$$\sum_{\sigma \in \Sigma_{G,H,\varepsilon}^{B_0, B_1, \tau}} \sum_{\Gamma \in \Omega_{G,H,\varepsilon}^{B_0, B_1}} w_{G,H}(\sigma) \leq \sum_{\sigma \in \Sigma_{G,H,\varepsilon}^{B_0, B_1, \tau}} w_{G,H}(\sigma),$$

and hence $Z_{G,H,\varepsilon}^{\text{polymer}} \leq Z_{G,H,\varepsilon}^{\text{polymer}}$. By Lemma 12, we obtain that $Z_{G,H,\varepsilon}^{\text{polymer}} \leq (1 + e^{-n/(4q)})Z_{G,H,\varepsilon}$.

This finishes the proof of Lemma 20.

4.4 Solving the polymer model

Let $q \geq 2, \Delta \geq 3$ be integers and $\delta \in (0, 1), \lambda \in (0, \Delta)$ be reals. Let $H \in \mathbb{R}^{q \times q}$ be a symmetric $\delta$-matrix and $(B_0, B_1) \in K_{G,\varepsilon}^\max$. For $\varepsilon \in (0, 1)$, we now show that the family of polymer models $\{(C_{G,H,\varepsilon}^{B_0, B_1}, w_{G,H}^{B_0, B_1}, J_G) \mid G \in \mathcal{G}_{G,H,\varepsilon}^{\text{bip}}\}$ which was defined in the previous subsection is computationally feasible and satisfies the polymer sampling condition.

Lemma 21. Let $\varepsilon \in (0, 1)$ be such that $\varepsilon \geq \lambda^2/\Delta^2$ and $\varepsilon \leq \frac{1-\delta}{4\log(q/\Delta^2)\lambda}$. The family of polymer models $\{(C_{G,H,\varepsilon}^{B_0, B_1}, w_{G,H}^{B_0, B_1}, J_G) \mid G \in \mathcal{G}_{G,H,\varepsilon}^{\text{bip}}\}$ is computationally feasible and satisfies the polymer sampling condition with constant $\tau \geq 5 + 3\log((q - 1)\Delta)$.

Proof. Consider an arbitrary polymer $\gamma = (V_\gamma, \sigma_\gamma) \in \mathcal{P}_{G,H}^{B_0, B_1}$.

We first verify computational feasibility by showing that we can determine whether $\gamma \in C_{G,H,\varepsilon}^{B_0, B_1}$ and, if so, compute its weight $w_{G,H}^{B_0, B_1}(\gamma)$ in time $O(|V_\gamma|)$. Indeed, we have that $\gamma \in C_{G,H,\varepsilon}^{B_0, B_1}$ iff $|V_\gamma| \leq 2\varepsilon n$ and $\sigma_\gamma$ maps $V_\gamma \cap V^i_G$ to $[q] \setminus B_i$ for each $i \in \{0, 1\}$, which can be clearly checked in time $O(|V_\gamma|)$. To compute $w_{G,H}^{B_0, B_1}(\gamma)$, recall from (10) that

$$w_{G,H}^{B_0, B_1}(\gamma) = \prod_{\{u,v\} \in E_G(V_\gamma)} H_{\sigma_\gamma(u), \sigma_\gamma(v)} \prod_{u \in \partial V_\gamma} F_u / \prod_{i \in \{0, 1\}} |B_i|^{V^i_G \setminus V^i_G\gamma}|. \quad (10)$$
where for a vertex \( u \in V_G \cap \partial V_\gamma \) with \( i \in \{0, 1\} \), \( F_u := \sum_{j \in B_i} \prod_{v \in \partial u \cap V_\gamma} H_j,_{\sigma_v(v)} \). It follows that the r.h.s. in (10) can be computed in \( O(|V_\gamma|) \) time, using that \( |\partial V_\gamma| \leq \Delta |V_\gamma| \).

We next verify the polymer sampling condition. From (10), using that the entries of \( H \) are at most 1, we have the bound

\[
w_{G,H}^{B_0,B_1}(\gamma) \leq \frac{\prod_{u \in \partial V_\gamma \cap V_G} F_u}{\prod_{i \in \{0,1\}} |B_i|^{|V_G \cap \partial V_\gamma^+|}}.
\]

Let us now consider the factor \( F_u \) for \( u \in \partial V_\gamma \cap V_G^i \) with \( i \in \{0, 1\} \). Let \( v \) be a neighbour of \( u \) in \( V_\gamma \cap V_G^i \); such \( v \) exists since \( u \in \partial V_\gamma \cap V_G^i \). Then, there exists \( j \in B_i \) such that \( H_j,_{\sigma_v(v)} \leq \delta \); otherwise \( (B_i, B_i \cup \{\sigma_v(v)\}) \) would also be a biclique of \( H \), contradicting the maximality of \( (B_0, B_1) \) (since \( \sigma_v(v) \notin B_{i \pm 1} \)). It follows that \( F_u \leq |B_i| - 1 + \delta \). Using this in (13), we get that

\[
w_{G,H}^{B_0,B_1}(\gamma) \leq \frac{\prod_{i \in \{0,1\}}(|B_i| - 1 + \delta)^{|\partial V_\gamma \cap V_G^i|}}{\prod_{i \in \{0,1\}} |B_i|^{|V_G \cap \partial V_\gamma^+|}} \leq \left(1 - \frac{1 - \delta}{q}\right)^{|\partial V_\gamma|} \leq e^{-|\partial V_\gamma|/q},
\]

where in the second to last inequality we used that \( |V_G^+ \cap V_G^i| \geq |\partial V_\gamma \cap V_G^i| \) for \( i \in \{0, 1\} \).

We next lower bound \( |\partial V_\gamma| \) in terms of \( |V_\gamma| \). For \( i \in \{0, 1\} \), let \( \rho_i = |V_\gamma \cap V_G^i|/n \) and \( \rho = |V_\gamma|/n \). Applying Lemma 8 to the set \( V_\gamma \cap V_G^i \), we have that

\[
|\partial(V_\gamma \cap V_G^i)| \geq \frac{|V_\gamma \cap V_G^i|}{\rho_i + \frac{\rho_i^2}{3}(1 - \rho_i)} \geq \frac{|V_\gamma \cap V_G^i|}{\rho + \frac{\rho^2}{3}}.
\]

Now observe that

\[
\sum_{i \in \{0,1\}} \rho_i |V_\gamma \cap V_G^i| = \frac{1}{n} \sum_{i \in \{0,1\}} |V_\gamma \cap V_G^i| \leq \frac{1}{n} |V_\gamma|^2 = \rho |V_\gamma|
\]

and hence, using the inequality \( \frac{a}{x} + \frac{b}{y} \geq \frac{(a+b)^2}{ax+by} \) which holds for all \( a, b, x, y \geq 0 \), we obtain

\[
\sum_{i \in \{0,1\}} |\partial(V_\gamma \cap V_G^i)| \geq \sum_{i \in \{0,1\}} \frac{|V_\gamma \cap V_G^i|}{\rho_i + \frac{\rho_i^2}{3}(1 - \rho_i)} \geq \frac{|V_\gamma|}{\rho + \frac{\rho^2}{3}} \geq \frac{|V_\gamma|}{3\varepsilon}.
\]

using that \( \rho \leq 2\varepsilon \) and \( \varepsilon \geq \frac{\lambda_2}{4\varepsilon} \). Since \( \varepsilon \in (0, 1/20) \), we have that \( |\partial V_\gamma| \geq \frac{|V_\gamma|}{3\varepsilon} \geq \frac{|V_\gamma|}{4\varepsilon} \).

Plugging this into (14), we obtain

\[
w_{G,H}^{B_0,B_1}(\gamma) \leq e^{-|V_\gamma|/(4\varepsilon q)} \leq e^{-\tau |V_\gamma|},
\]

where \( \tau := \frac{4\varepsilon q}{4\varepsilon q} \geq 10 \log(q\Delta) \geq 5 + 3 \log((q-1)\Delta^3) \) using that \( \varepsilon \leq \frac{1 - \delta}{\log(q\Delta)} \) and \( q \geq 2, \Delta \geq 3 \). This finishes the proof of Lemma 21, after observing that the degree bound for the family \( \{w_{G,H}^{B_0,B_1}, w_{G,H}^{B_0,B_1}, J_G \} | G \in \mathcal{G}_\Delta \} \) is \( \Delta^3 \).

Finally, we can apply Theorem 15, which gives us an efficient algorithm for approximating the partition function of the polymer model.

14
Corollary 22. Let \( q \geq 2, \delta \in (0, 1), H \in \mathbb{R}_{\geq 0}^{q \times q} \) be a symmetric \( \delta \)-matrix, and \((B_0, B_1) \in K_{\Delta}^{\text{max}} \). Let \( \varepsilon \in (0, 1) \) be such that \( \varepsilon \geq \lambda^2 / \Delta^2 \) and \( \varepsilon \leq \frac{1 - \delta}{40q \log(q \Delta)} \).

Then, there is a randomised algorithm that takes as input an \( n \)-vertex graph \( G \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) and an accuracy parameter \( \varepsilon^{\ast} \in (0, 1) \) and outputs an \( \varepsilon^{\ast} \)-approximation to \( Z_{G,H}^{B_0,B_1} \) in time \( O((n/\varepsilon^*)^2 \log^2(n/\varepsilon^*)) \) with probability \( \geq 3/4 \). Moreover, there is a randomised algorithm that on input \( G \) and \( \varepsilon^{\ast} \) as before, outputs an \( \varepsilon^{\ast} \)-approximate sample from \( \mu_{G,H}^{B_0,B_1} \) in time \( O(n \log(n/\varepsilon^*)) \).

5 Proof of Theorem 3

In this section, we combine the results of Sections 3 and 4 to prove Theorem 3.

Theorem 3. Let \( q \geq 2 \) be an integer, \( \delta \) be a real in \((0, 1)\), \( H \in \mathbb{R}_{\geq 0}^{q \times q} \) be a symmetric \( \delta \)-matrix. Suppose that \( \Delta, \lambda \) satisfy \( \Delta \geq \frac{100}{1-q^2} q^2 \log(q \Delta) \) and \( \Delta \geq \left( \frac{10}{1-q^2} q \log(q \Delta) \right)^4 \). Then, there is an FPRAS for \( \mathcal{S}^{\text{PIR}}_{\Delta, \lambda} \).

In fact, there is a randomised algorithm that, given a graph \( G \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) with \( n = |V_G^0| = |V_G^1| \) vertices and an accuracy parameter \( \varepsilon^{\ast} \geq e^{-n/(4q)} \), outputs an \( \varepsilon^{\ast} \)-approximation to \( Z_{G,H} \) and an \( \varepsilon^{\ast} \)-sample from the Gibbs distribution \( \mu_{G,H} \) in time \( O((n/\varepsilon^*)^2 \log^2(n/\varepsilon^*)) \).

Proof. As input to the FPRAS, we are given a graph \( G \in \mathcal{G}_{\Delta, \lambda}^{\text{bip}} \) and an accuracy parameter \( \varepsilon^{\ast} \in (0, 1) \). We may assume that \( n = |V_G^0| = |V_G^1| \) is sufficiently large, otherwise we can compute \( Z_{G,H} \) exactly in constant time, by brute force. Similarly, we may assume that \( \varepsilon^{\ast} \geq 9e^{-n/(4q)} \), otherwise we can compute \( Z_{G,H} \) exactly in \( O(nq^{2n}) = poly(1/\varepsilon^*) \) time, by brute force.

Let \( \varepsilon = \frac{1 - \delta}{40q \log(q \Delta)} \) and observe that, using the lower bounds on \( \frac{A}{\Delta} \) and \( \Delta \), we have that

\[
\varepsilon \leq \frac{1}{240q \log q}, \quad \varepsilon \geq \frac{2q}{\Delta^2}, \quad \varepsilon^2 \geq \frac{8q^2 \log q}{\Delta \log(1/\delta)},
\]

where the first inequality follows from \( \Delta \geq q^4 \), the second from rearranging \( \frac{A}{\Delta} \geq \frac{2q}{\varepsilon} \) (using the lower bound on \( \frac{A}{\Delta} \)), and the last inequality from using that \( \log(1/\delta) \geq 1 - \delta \) for all \( \delta \in (0, 1) \). In particular, the assumption of Lemmas 10, 20 and Corollary 22 are satisfied.

By Corollary 22, for an arbitrary biclique \((B_0, B_1) \in K_{\Delta}^{\text{max}} \), we can obtain an \((\varepsilon^*/8)\)-approximation to \( Z_{G,H,B_0,B_1} \) in \( O((n/\varepsilon^*)^2 \log^2(n/\varepsilon^*)) \) time, with probability at least \( 3/4 \). Taking the median of \( O(\log(1/\varepsilon^*)) \) runs of this algorithm, we therefore obtain \( \hat{Z}_{G,H,B_0,B_1} \) which is an \((\varepsilon^*/8)\)-approximation to \( Z_{G,H,B_0,B_1} \) with probability at least \( 1 - \varepsilon^*/(16|K_{\Delta}^{\text{max}}|) \). By a union bound over the bicliques in \( K_{\Delta}^{\text{max}} \), it follows that

\[
\hat{Z}_{G,H}^{\text{polymer}} := \sum_{(B_0, B_1) \in K_{\Delta}^{\text{max}}} |B_0|^n |B_1|^n \cdot \hat{Z}_{G,H,B_0,B_1}^{B_0,B_1},
\]

is an \((\varepsilon^*/8)\)-approximation to \( \hat{Z}_{G,H}^{\text{polymer}} \) (cf. Definition 18) with probability at least \( 1 - \varepsilon^*/16 \). By Lemma 20, \( \hat{Z}_{G,H}^{\text{polymer}} \) is an \((\varepsilon^*/8)\)-approximation to \( Z_{G,H}^{B_0,B_1} \) which, by Lemma 10, is an \((\varepsilon^*/8)\)-approximation to \( Z_{G,H} \). It therefore follows that \( \hat{Z}_{G,H}^{\text{polymer}} \) is a \((3\varepsilon^*/8)\)-approximation,
and hence an \( \varepsilon^* \)-approximation, to \( Z_{G,H} \) with probability at least \( 1 - \varepsilon^*/16 \). The total runtime of the algorithm is therefore \( O((n/\varepsilon)^2 \log^3(n/\varepsilon^*)) \).

For the sampling algorithm, we assume again that \( \varepsilon^* \geq 9e^{-n/(4q)} \). We first sample a biclique \( \hat{B} = (B_0, B_1) \in K_H^{\text{max}} \) with probability \( |B_0|^n |B_1|^n \frac{Z_{B_0,B_1}}{Z_{G,H,\varepsilon}} \), where \( Z_{G,H,\varepsilon} \) and \( Z_{G,H,\varepsilon}^{\text{polymer}} \) are as before. Then, using Corollary 22, we sample a polymer configuration \( \hat{\Gamma} \) whose distribution is at distance at most \( \varepsilon^*/6 \) from \( \mu_{G,H,\varepsilon} \). We output \( \hat{\sigma} = \text{Spin}_B(\hat{\Gamma}) \), where for a biclique \( B = (B_0, B_1) \) and a polymer configuration \( \Gamma \), \( \text{Spin}_B(\Gamma) \) is a random configuration \( \tau \) obtained as follows:

- For every vertex \( u \in \cup \Gamma \), we set \( \tau(u) = \sigma_\Gamma(u) \).
- For \( u \in V_G \setminus (\cup \Gamma)^+ \) with \( i \in \{0,1\} \), we assign a random spin from \( B_i \) uniformly at random.
- For \( u \in \partial(\cup \Gamma) \cap V_G \setminus (\cup \Gamma)^+ \) with \( i \in \{0,1\} \), for \( j \in B_i \) we set \( \tau(u) = j \) with probability \( \frac{1}{2} \prod_{v \in \partial u \setminus (\cup \Gamma)} H_{j,\tau(v)} \) where \( F_u := \sum_{j \in B_i} \prod_{v \in \partial u \setminus (\cup \Gamma)} H_{j,\tau(v)} \).

We claim that \( \hat{\sigma} \) is an \( \varepsilon^* \)-approximate sample from the Gibbs distribution \( \mu_{G,H} \). To prove this, let \( B, \Gamma, \sigma \) be the analogues of \( \hat{B}, \hat{\Gamma}, \hat{\sigma} \), respectively, when there is no error, more precisely:

1. \( B = (B_0, B_1) \) with probability \( |B_0|^n |B_1|^n \frac{Z_{B_0,B_1}}{Z_{G,H,\varepsilon}} \) and \( \sigma = \text{Spin}_B(\Gamma) \).

With probability \( 1 - \varepsilon^*/16 \), we have that, for all bicliques \( (B_0, B_1) \in K_H^{\text{max}} \), \( \hat{Z}_{B_0,B_1} \) and \( \hat{Z}_{G,H,\varepsilon}^{\text{polymer}} \) are \( (\varepsilon^*/8) \)-approximations to \( Z_{B_0,B_1} \) and \( Z_{G,H,\varepsilon}^{\text{polymer}} \) respectively, and conditioned on this the total variation distance between the distributions of \( \hat{B} \) and \( B \) is at most \( \frac{1+\varepsilon^*}{8} - 1 \leq 3\varepsilon^*/8 \). It follows that the total variation distance between the distributions of \( \hat{\Gamma} \) and \( \Gamma \) is at most \( 3\varepsilon^*/8 + \varepsilon^*/16 \leq \varepsilon^*/2 \), and there is a coupling so that \( \Pr[\hat{\Gamma} \neq \Gamma | \hat{B} = B] \leq \varepsilon^*/2 \). Conditioned on \( \hat{B} = B \), we have that the total variation distance between \( \hat{\Gamma} \) and \( \Gamma \) is at most \( \varepsilon^*/6 \), so there is a coupling which further satisfies \( \Pr[\hat{\Gamma} \neq \Gamma | \hat{B} = B] \leq \varepsilon^*/4 \). Finally, conditioned on \( \hat{B} = B \) and \( \hat{\Gamma} = \Gamma \), we can clearly couple \( \hat{\sigma} \) and \( \sigma \) so that they agree. It follows that the total variation distance between \( \hat{\sigma} \) and \( \sigma \) it at most \( 2\varepsilon^*/3 \), so the result will follow by showing that the distribution of \( \sigma \) and \( \mu_{G,H} \) are at distance at most \( 3e^{-n/(4q)} \leq \varepsilon^*/3 \).

For this, we will consider the set of configurations \( \hat{\Sigma} := \Sigma_{G,H,\varepsilon} \setminus \Sigma_{\text{overlap}} \) where recall from Definition 9 that \( \Sigma_{G,H,\varepsilon} \) is the set of configurations \( \tau \) with \( \sum_{i \in \{0,1\}} |\tau^{-1}(B_i) \cap V_G| \geq (1 - \varepsilon)|V_G| \), and from Definition 11 that \( \Sigma_{\text{overlap}} \) is the set of configurations \( \tau \) such that \( \tau \in \Sigma_{B_0,B_1} \cap \Sigma_{C_0,C_1} \) for some distinct maximal bicliques \( (B_0, B_1), (C_0, C_1) \).

Consider arbitrary \( \tau \in \hat{\Sigma} \) and let \( (B_0, B_1) \) be such that \( \tau \in \Sigma_{B_0,B_1} \). For \( i \in \{0,1\} \), let \( T_i = V_G \cap \tau^{-1}(g_i \backslash B_i) \), and \( S_1, \ldots, S_k \) denote the \( G \)-connected components of \( T := T_0 \cup T_1 \); note, since \( \tau \in \hat{\Sigma} \), we have \( |T| \leq \varepsilon|V_G| \). Consider the polymer configuration \( \Gamma \), which is the union of the polymers \( (S_1, \tau|_{S_1}), \ldots, (S_k, \tau|_{S_k}) \). We next find how the sample \( \sigma \) can equal \( \tau \); we claim that

\[
\sigma = \tau \text{ iff } B = (B_0, B_1), \quad \Gamma = \Gamma_\tau, \quad \sigma|_{V_G \setminus (\cup \Gamma)} = \tau|_{V_G \setminus T}.
\]
The reverse direction of this equivalence is immediate, noting that the equality $\Gamma = \Gamma_\tau$ implies that $(\cup \Gamma) = T$ and that $\sigma|_{\cup \Gamma} = \tau|_T$. So, we focus on the forward direction and assume that $\sigma = \tau$. Then:

1. $B = (B_0, B_1)$. Otherwise, if $B = (C_0, C_1)$ for some $(C_0, C_1) \neq (B_0, B_1)$, then by Lemma 19 we would have that $\tau \in \Sigma_{G,H,3\epsilon}$, contradicting that $\tau \not\in \Sigma_{G,H,3\epsilon}$. 

2. $\cup \Gamma = T_0 \cup T_1$. Since $B = (B_0, B_1)$ from Item 1, for $i \in \{0, 1\}$ we have that $u \in V'_G \cap (\cup \Gamma)$ iff $\sigma(u) \in [q]\setminus B_i$ iff $\tau(u) \in [q]\setminus B_i$ iff $u \in T_i$. 

3. $\sigma|_{\cup \Gamma} = \tau|_T$ and $\sigma|_{V_G \setminus (\cup \Gamma)} = \tau|_{V_G \setminus T}$. This follows from Item 2 and $\sigma = \tau$. 

4. $\Gamma = \Gamma_\tau$. This follows from Items 2 and 3.

From (15) and the definition of the sampling procedure for $\sigma$, we therefore have that $\sigma = \tau$ with probability

$$
\frac{|B_0|^n |B_1|^n Z_{G,H,\epsilon}^{B_0,B_1}}{Z_{G,H,\epsilon}^{polymer}} \cdot \prod_{i \in \{0,1\}} \frac{1}{|B_i| V_G^{\cup T^+}} \prod_{u \in \partial T} \left( \frac{1}{F_u} \prod_{v \in T \cap \partial u} H_{\tau(u), \tau(v)} \right). 
$$

(16)

From (11) applied to the polymer configuration $\Gamma_\tau$, we have, using that $\cup \Gamma_\tau = T$ and $\sigma_{\Gamma_\tau} = \tau$, that

$$
|B_0|^n |B_1|^n w_{G,H,\epsilon}^{B_0,B_1} (\Gamma_\tau) = \prod_{i \in \{0,1\}} |B_i| V_G^{\cup T^+} \prod_{\{u,v\} \in E_G(T)} H_{\tau(u), \tau(v)} \prod_{u \in \partial T} F_u,
$$

and hence we obtain that the expression in (16) equals

$$
\frac{\prod_{\{u,v\} \in E_G(T)} H_{\tau(u), \tau(v)} \prod_{u \in \partial T} F_u}{Z_{G,H,\epsilon}^{polymer}} = \frac{w_{G,H}(\tau)}{Z_{G,H,\epsilon}^{polymer}},
$$

where the last equality follows by noting that edges that are not in $E_G(T) \cup E_G(T, \partial T)$ contribute a factor of 1 in the weight of $T$ (since their endpoints are assigned spins of the biclique). So, we have shown that $\sigma = \tau$ with probability $w_{G,H}(\tau) / Z_{G,H,\epsilon}^{polymer}$.

Let $p_\sigma$ be the probability that $\sigma \in \tilde{\Sigma}$ and $p$ be the aggregate weight of configurations in the Gibbs distribution $\mu_{G,H}$ in $\tilde{\Sigma}$. Then, using that $Z_{G,H,3\epsilon}^{overlap} \leq e^{-n/(4q)} Z_{G,H,\epsilon}$ from Lemma 12 and $Z_{G,H,\epsilon}^{polymer} \leq (1 + e^{-n/(4q)}) Z_{G,H,\epsilon}$ from Lemma 20, we have that

$$
p_\sigma \geq \frac{1}{Z_{G,H,\epsilon}^{polymer}} \sum_{\tau \in \tilde{\Sigma}} w_{G,H}(\tau) \geq \frac{Z_{G,H,\epsilon} - Z_{G,H,\epsilon}^{overlap}}{Z_{G,H,\epsilon}^{polymer}} \geq \left(1 - e^{-n/(4q)}\right) Z_{G,H,\epsilon} \geq 1 - 2e^{-n/(4q)},
$$

(17)

while for $p$, using that $Z_{G,H} \leq (1 + e^{-n}) Z_{G,H,\epsilon}$ from Lemma 10, we have the bound

$$
p \geq \frac{1}{Z_{G,H}} \sum_{\tau \in \tilde{\Sigma}} w_{G,H}(\tau) \geq \frac{Z_{G,H,\epsilon} - Z_{G,H,\epsilon}^{overlap}}{Z_{G,H}} \geq \left(1 - e^{-n/(4q)}\right) Z_{G,H,\epsilon} \geq 1 - 2e^{-n/(3q)}. 
$$

(18)

It follows that the total variation distance between the distribution of $\sigma$ and $\mu_{G,H}$ is bounded above by

$$
D := \frac{1}{2} \left( (1 - p_\sigma) + (1 - p) + M \right), \quad \text{where} \quad M := \sum_{\tau \in \tilde{\Sigma}} w_{G,H}(\tau) \left| \frac{1}{Z_{G,H,\epsilon}^{polymer}} - \frac{1}{Z_{G,H}} \right|,
$$

17
Using Lemma 10 and Lemma 20, we have the bound
\[ M \leq \left| \frac{Z_{G,H}}{Z_{G,H,\varepsilon}} - 1 \right| \leq 2e^{-n/(4q)}. \quad (19) \]

Combining (17), (18), and (19), we obtain that \( D \leq 3e^{-n/(4q)} \), i.e., the distance between the distribution of \( \sigma \) and \( \mu_{G,H} \) is at most \( 3e^{-n/(4q)} \), as claimed.

This finishes the proof of Theorem 3. \( \square \)
