Received: date / Accepted: date

Abstract The quantum dynamics of scalar bosons embedded in the background of a magnetic cosmic string is considered. In this work, scalar bosons are described by the Duffin-Kemmer-Petiau (DKP) formalism. In particular, the effects of this topological defect in the equation of motion, energy spectrum and DKP spinor are analyzed and discussed in details. The exact solutions for the DKP oscillator in this background are presented in a closed form.

1 Introduction

The first-order Duffin-Kemmer-Petiau (DKP) formalism [1–4] describes spin-zero and spin-one particles and has been used to analyze relativistic interactions of spin-zero and spin-one hadrons with nuclei as an alternative to their conventional second-order Klein-Gordon (KG) and Proca counterparts. Although the formalisms are equivalent in the case of minimally coupled vector interactions [5–7], the DKP formalism enjoys a richness of couplings not capable of being expressed in the KG and Proca theories [8, 9]. Recently, there has been an increasing interest on the so-called DKP oscillator [10–19]. The DKP oscillator considering minimal length [20, 21] and noncommutative phase space [22–25] have also appeared in the literature. The DKP oscillator is a kind of tensor coupling with a linear potential which leads to the harmonic oscillator problem in the weak-coupling limit. Also, a sort of vector DKP oscillator (non-minimal vector coupling with a linear potential [26–30] has been an topic of recent investigation. Vector DKP oscillator is the name given to the system with a Lorentz vector coupling which exhibits an equally spaced energy spectrum in the weak-coupling limit. The name distinguishes from that system called DKP oscillator with Lorentz tensor couplings of Ref. [10–25].

The DKP oscillator is an analogous to Dirac oscillator [31]. The Dirac oscillator is a natural model for studying properties of physical systems, it is an exactly solvable model, several research have been developed in the context of this theoretical framework in recent years. A detailed description for the Dirac oscillator is given in Ref. [32] and for other contributions see Refs. [33–39]. The Dirac oscillator embedded in a magnetic cosmic string background has inspired a great deal of research in last years[40–46]. A cosmic string is a linear defect that change the topology of the medium when viewed globally. The influence of this topological defect in the dynamics of spin-1/2 particles has been widely discussed in the literature. However, the same problem involves bosons via DKP formalism has not been established. Therefore, we believe that this problem deserves to be explored.

The main motivation of this work is inspired by the results obtained in Ref. [46]. As a natural extension, we address the quantum dynamics of scalar bosons (via DKP formalism) embedded in the background of a magnetic cosmic string. The influence of this topological defect in the equation of motion, energy spectrum and DKP spinor are analyzed and discussed in details. The case of DKP oscillator in this background is also considered. In this case, the problem is mapped into a Schrödinger-like equation embedded in a three-dimensional harmonic oscillator for the first component of the DKP spinor and the remaining components are expressed in terms of the first one in a simple way. Our results are very similar to Dirac oscillator in a mag-
netic cosmic string background, except by the absence of terms that depend on the spin projection parameter.

This work is organized as follows. In section 2, we consider the DKP equation in a curved space-time. We discuss conditions on the interactions which lead to a conserved current in a curved space-time (section 2.1). In section 3, we give a brief review on a magnetic cosmic string. In particular, we focus the case of scalar bosons and obtain the equation of motion, energy spectrum and DKP spinor (section 4.1). Finally, in section 5 we present our conclusions.

2 Duffin-Kemmer-Petiau equation in a curved space-time

The Duffin-Kemmer-Petiau (DKP) equation for a free boson in curved space-time is given by \([47, 48] \) \((\hbar = c = 1)\)

\[
[i \beta^\mu \nabla_\mu - M] \Psi = 0
\]

(1)

where the covariant derivative

\[
\nabla_\mu = \partial_\mu - \Gamma_\mu.
\]

(2)

The affine connection is defined by

\[
\Gamma_\mu = \frac{1}{2} \omega_{\rho\alpha\beta}[\beta^\rho, \beta^\alpha].
\]

(3)

The curved-space beta matrices are

\[
\beta^\mu = \epsilon^\mu {\bar{a}} \beta^a
\]

(4)

and satisfy the algebra

\[
\beta^\mu \beta^\nu \beta^\lambda + \beta^\lambda \beta^\nu \beta^\mu = g^{\mu\nu} \beta^\lambda + g^{\lambda\nu} \beta^\mu.
\]

(5)

where \(g^{\mu\nu}\) is the metric tensor. The algebra expressed by (5) generates a set of 126 independent matrices whose irreducible representations are a trivial representation, a five-dimensional representation describing the spin-zero particles (scalar sector) and a ten-dimensional representation associated to spin-one particles (vector sector). The DKP spinor has an excess of components and the theory has to be supplemented by an equation which allows one to eliminate the superfluous components. That constraint equation is obtained by multiplying the Eq. (1) by \(1 - \beta^0 \beta^0\) from the left, namely

\[
i \beta^1 \beta^0 \beta^0 \nabla_j \Psi = M \left(1 - \beta^0 \beta^0\right) \Psi
\]

(6)

This constraint equation expresses three (four) components of the spinor by the other two (six) components and their space covariant derive in the scalar (vector) sector so that the redundant components disappear and there only remain the physical components of the DKP theory.

The tetrad \(e_\mu {\bar{a}}(x)\) satisfy the relations

\[
\eta^{\alpha\beta} = e_\mu {\bar{a}} e_\nu {\bar{b}} g_{\mu\nu}
\]

(7)

\[
g_{\mu\nu} = e_\mu {\bar{a}} e_\nu {\bar{b}} \eta_{\alpha\beta}
\]

(8)

and

\[
e_\mu {\bar{a}} e_\mu {\bar{b}} = \delta_0 {\bar{b}}
\]

(9)

the Latin indexes being raised and lowered by the Minkowski metric tensor \(\eta^{\alpha\beta}\) with signature \((-+, +, +, +)\) and the Greek ones by the metric tensor \(g^{\mu\nu}\).

The spin connection \(\omega_{\mu\alpha\beta}\) is given by

\[
\omega_{\mu\alpha\beta} = e_\alpha {\bar{a}} e_\beta {\bar{b}} \Gamma_{\mu\alpha\beta}^{\alpha} - e_\alpha {\bar{a}} \partial_\mu e_\nu {\bar{b}}
\]

(10)

with \(\omega_{\mu\alpha\beta} = -\omega_{\mu\beta\alpha}\) and \(\Gamma_{\mu\alpha\beta}^{\alpha}\) are the Christoffel symbols given by

\[
\Gamma_{\mu\alpha\beta}^{\alpha} = \frac{g_{\alpha\beta}}{2} \left(\partial_\mu g_{\beta\nu} + \partial_\nu g_{\beta\mu} - \partial_\beta g_{\mu\nu}\right).
\]

(11)

In this stage, it is useful to consider the current. The conservation law for \(J^\mu\) follows from the standard procedure of multiplying (1) and its complex conjugate by \(\bar{\Psi}\) from the left and by \(\eta^{\mu\bar{b}}\Psi\) from the right, respectively. The sum of those resulting equations leads to

\[
\nabla_\mu J^\mu = \frac{1}{2} \bar{\Psi} \left(\nabla_\mu \beta^\mu\right) \Psi
\]

(12)

where \(J^\mu = \frac{1}{2} \bar{\Psi} \beta^\mu \Psi\). The factor 1/2 multiplying \(\bar{\Psi} \beta^\mu \Psi\), of no importance regarding the conservation law, is in order to hand over a charge density conformable to that one used in the KG theory and its nonrelativistic limit \([27]\). The adjoint spinor \(\bar{\Psi}\) is given by \(\bar{\Psi} = \Psi^\dagger \eta^0\) with \(\eta^0 = 2 \beta^0 \beta^0 - 1\) in such a way that \((\eta^0 \beta^\mu)^\dagger = \eta^0 \beta^\mu\) (the matrices \(\beta^\mu\) are Hermitian with respect to \(\bar{\eta}\)). Despite the similarity to the Dirac equation, the DKP equation involves singular matrices, the time component of \(J^\mu\) is not positive definite and the case of massless bosons cannot be obtained by a limiting process \([49]\). Nevertheless, the matrices \(\beta^\mu\) plus the unit operator generate a ring consistent with integer-spin algebra and \(J^0\) may be interpreted as a charge density. Thus, if

\[
\nabla_\mu \beta^\mu = 0
\]

(13)

then four-current will be conserved. The condition (13) is the purely geometrical assertion that the curved-space beta matrices are covariantly constant.
The normalization condition \( \int d\tau J^0 = \pm 1 \) can be expressed as

\[
\int d\tau \Psi \beta^0 \Psi = \pm 2,
\]
where the plus (minus) sign must be used for a positive (negative) charge.

2.1 Interaction in the Duffin-Kemmer-Petiau equation

With the introduction of interactions, the DKP equation in a curved space-time can be written as

\[
(i \beta^\mu \nabla_\mu - m - U) \Psi = 0
\]
where the more general potential matrix \( U \) is written in terms of 25 (100) linearly independent matrices pertinent to five (ten)-dimensional irreducible representation associated to the scalar (vector) sector. In the presence of interaction, \( J^\mu \) satisfies the equation

\[
\nabla_\mu J^\mu + \frac{i}{2} \Psi (U - \eta^0 U^\dagger \eta^0) \Psi = \frac{1}{2} \nabla_\mu (\beta^\mu) \Psi
\]
Thus, if \( U \) is Hermitian with respect to \( \eta^0 \) and the curved-space beta matrices are covariantly constant then four-current will be conserved. The potential matrix \( U \) can be written in terms of well-defined Lorentz structures. For the spin-zero sector there are two scalar, two vector and two tensor terms [8], whereas for the spin-one sector there are two scalar, two vector, a pseudoscalar, two pseudovector and eight tensor terms [9].

The condition (16) for the case of Minkowski space-time has been used to point out a misleading treatment in the recent literature regarding analytical solutions for nonminimal vector interactions [30, 50–52].

3 Magnetic cosmic string background

The cosmic string space-time with an internal magnetic field is an object described by the line element

\[
ds^2 = -dt^2 + dr^2 + \alpha^2 r^2 d\varphi^2 + dz^2
\]
in cylindrical coordinates \((t, r, \varphi, z)\), where \(-\infty < \varphi < +\infty\), \( r \geq 0 \) and \( 0 \leq \varphi \leq 2\pi\). The parameter \( \alpha \) is associated with the linear mass density \( \tilde{m} \) of the string by \( \alpha = 1 - 4\tilde{m} \) and runs in the interval \((0, 1]\) and corresponds to a deficit angle \( \gamma = 2\pi(1-\alpha) \). In the geometric context, the line element (17) is related to a Minkowski space-time with a conical singularity [53]. Note that, in the limit as \( \alpha \to 1 \) we obtain the line element of cylindrical coordinates.

The basis tetrad \( e^\mu_a \) from the line element (17) is chosen to be

\[
e^\mu_a = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & \cos \varphi & \sin \varphi & 0 \\
0 & -\sin \varphi & \cos \varphi & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}.
\]

For the specific basis tetrad (18) the curved-space beta matrices read

\[
\begin{align*}
\beta^0 &= \beta^0, \\
\beta^1 &= \beta^1 \cos \varphi + \beta^2 \sin \varphi, \\
\beta^2 &= -\beta^1 \sin \varphi + \beta^2 \cos \varphi, \\
\beta^3 &= \beta^3,
\end{align*}
\]

and the spin connection is given by

\[
\Gamma_\varphi = (1 - \alpha) \left[ \beta^1, \beta^2 \right].
\]

Thereby, the covariant derivative gets

\[
\begin{align*}
\nabla_0 &= \partial_0, \\
\nabla_r &= \partial_r, \\
\nabla_\varphi &= \partial_\varphi - (1 - \alpha) \left[ \beta^1, \beta^2 \right], \\
\nabla_z &= \partial_z
\end{align*}
\]

Now we focus attention on the condition (13) for a magnetic cosmic string background. Using the line element (17) and the representation for the curved-space beta matrices (19), (20), (21) and (22) the condition (13) is satisfied and therefore the current is conserved for this background. Having set up the DKP equation in a magnetic cosmic string background, we are now in a position to use the machinery developed above in order to solve the DKP equation in this background with some specific forms for external interactions.

4 DKP oscillator in a magnetic cosmic string background

In this section, we concentrate our efforts in the interaction called DKP oscillator embedded in the background of a magnetic cosmic string. For this external interaction we use the non-minimal substitution [11]

\[
p \rightarrow p - iM\omega \eta^0 \mathbf{r}
\]
where \( \omega \) is the oscillator frequency. This interaction is a Lorentz-tensor type and is Hermitian with respect to \( \eta^0 \), so it furnishes a conserved four-current. Considering only the radial component the non-minimal substitution gets

\[
p \rightarrow p - iM\omega \eta^0 \mathbf{r}.
\]
As the interaction is time-independent one can write \( \psi(r,t) = \Phi(r) \exp(-iEt) \), where \( E \) is the energy of the scalar boson, in such a way that the time-independent DKP equation becomes

\[
\left[ \beta^0 E + i \beta^r (\partial_r + M \omega \phi^0_r) + i \beta^\varphi \nabla_\varphi + i \beta^3 \partial_z - M \right] \Phi = 0
\]  

(30)

where \( \beta^r, \beta^\varphi \) and \( \nabla_\varphi \) are given by (20), (21) and (26), respectively.

4.1 Scalar sector

For the case of scalar bosons (scalar sector), we use the standard representation for the beta matrices given by [54]

\[
\beta^0 = \begin{pmatrix} \theta & \bar{n} \\ \bar{n}^T & 0 \end{pmatrix}, \quad \beta^\varphi = \begin{pmatrix} 0 & \bar{r} \\ \bar{r}^T & 0 \end{pmatrix}
\]

(31)

where

\[
\theta = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \rho^1 = \begin{pmatrix} -1 & 0 \\ 0 & 0 \end{pmatrix}
\]

\[
\rho^2 = \begin{pmatrix} 0 & -1 \\ 0 & 1 \end{pmatrix}, \quad \rho^3 = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}
\]

\( \bar{n}, \bar{\bar{n}} \) and \( 0 \) are \( 2 \times 3, 2 \times 2 \) and \( 3 \times 3 \) zero matrices, respectively, while the superscript \( T \) designates matrix transposition. The five-component spinor can be written as \( \Phi^T = (\Phi_1, \ldots, \Phi_5) \) and the DKP equation for scalar bosons becomes

\[
E\Phi_2 - M \Phi_1 - i (\partial_r - \delta_0 \cos \varphi) \Phi_3 - i (\partial_\varphi - \delta_0 \sin \varphi) \Phi_4 - i \partial_z \Phi_5 = 0,
\]

(33)

\[
\Phi_2 = \frac{E}{M} \Phi_1,
\]

(34)

\[
\Phi_3 = \frac{i}{M} (\partial_r + M \omega \cos \varphi) \Phi_1,
\]

(35)

\[
\Phi_4 = \frac{i}{M} (\partial_\varphi + M \omega \sin \varphi) \Phi_1,
\]

(36)

\[
\Phi_5 = \frac{1}{M} \partial_z \Phi_1,
\]

(37)

where

\[
\partial_\varphi = \cos \varphi \partial_r - \frac{\sin \varphi}{\alpha r} \partial_\varphi,
\]

(38)

\[
\partial_\varphi = \sin \varphi \partial_r + \frac{\cos \varphi}{\alpha r} \partial_\varphi
\]

(39)

and

\[
\delta_0 = \frac{1 - \alpha}{\alpha r} + M \omega r.
\]

(40)

Meanwhile,

\[
J^0 = \text{Re}(\Phi_2^* \Phi_1) = \frac{E}{M} |\Phi_1|^2.
\]

(41)

Combining these results we obtain a equation of motion for the first component of the DKP spinor

\[
[\nabla^2_\alpha - M^2 \omega^2 r^2 + E^2 - M^2 + 2M \omega] \Phi_1 = 0
\]

(42)

where \( \nabla^2_\alpha \) is the Laplacian-Beltrami operator in the conical space and is given by

\[
\nabla^2_\alpha = \frac{1}{r} \frac{\partial}{\partial r} \left( r \frac{\partial}{\partial r} \right) + \frac{1}{\alpha^2 r^2} \frac{\partial^2}{\partial \varphi^2} + \frac{\partial^2}{\partial z^2}.
\]

(43)

At this stage, we can use the invariance under boosts along the z-direction and adopt the usual decomposition

\[
\Phi_1(r, \varphi, z) = \phi_1(r) e^{i m \varphi + i k_z z}
\]

(44)

with \( m \in \mathbb{Z} \). Inserting this into Eq. (42), we get

\[
\left[ \frac{d^2}{dr^2} - \lambda^2 r^2 - \frac{(m_\alpha - \frac{1}{2})^2}{r^2} + \kappa^2 \right] \phi_1 = 0
\]

(45)

where \( m_\alpha = m/\alpha, \lambda = M \omega \) and \( \kappa = \sqrt{E^2 - M^2 + 2M \omega - k_z^2} \).

The motion equation (45) describes the quantum dynamics of a DKP oscillator in a magnetic cosmic string background. With \( \phi_1(0) = 0 \) and \( \int_0^\infty \phi_1^* \phi_1 < \infty \), the solution for (45) with \( \kappa \) and \( \lambda \) real is precisely the well-known solution of the Schrödinger equation for the harmonic oscillator. The solution close to the origin valid for all values de \( m_\alpha \) can be written as being proportional to \( r^{m_\alpha + \frac{1}{2}} \). On the other hand, for large \( r \) the square-integrable solution behaves as \( e^{-\lambda r^2/2} \), thereby the solution for all \( r \) can be expressed as

\[
\phi_1(r) = r^{m_\alpha + \frac{1}{2}} e^{-\lambda r^2/2} f(r),
\]

(47)

subsequently, by introducing the following new variable and parameters:

\[
\rho = \lambda r^2,
\]

(48)

\[
\alpha = \frac{1}{2} \left( |m_\alpha| + 1 - \frac{\kappa^2}{2\lambda} \right),
\]

(49)

\[
b = |m_\alpha| + 1,
\]

(50)

one finds that \( f(\rho) \) can be expressed as a regular solution of the confluent hypergeometric equation (Kummer’s function) [55],

\[
\rho \frac{d^2 f}{d\rho^2} + (b - \rho) \frac{df}{d\rho} - af = 0.
\]

(51)
The general solution of (51) is given by [55]

$$f(\rho) = AM(a, b, \rho) + B\rho^{1-b}M(a - b + 1, 2 - b, \rho)$$

(52)

where A and B are arbitrary constants. The second term in (52) has a singular point at $\rho = 0$, so that we set $B = 0$. The asymptotic behavior of Kummer’s function is dictated by

$$M(a, b, \rho) \simeq \frac{\Gamma(b)}{\Gamma(b - a)} \frac{e^{-\pi a} \rho^{-a}}{\Gamma(a)} + \frac{\Gamma(b)}{\Gamma(a)} e^{\rho - b}.$$  

(53)

It is true that the presence of $e^\rho$ in the asymptotic behavior of $M(a, b, \rho)$ perverts the normalizability of $\phi_1(\rho)$. Nevertheless, this unfavorable behavior can be remedied by demanding $a = -n$, where $n$ is a non-negative integer and $b \neq -\bar{n}$, where $\bar{n}$ is also a non-negative integer. In fact, $M(-n, b, \rho)$ with $b > 0$ is proportional to the generalized Laguerre polynomial $L_n^{b-1}(\rho)$, a polynomial of degree $n$ with $n$ distinct positive zeros in the range $[0, \infty)$. Therefore, the solution for all $r$ can be written as

$$\phi_1(r) = N_n e^{\alpha r} \left( \frac{e^{-\lambda r^2/2} L_n^{m_\alpha}(\lambda r^2)}{\sqrt{\frac{2M\lambda^{m_\alpha} + 1}{|E| \Gamma(|m_\alpha| + n + 1)}}} \right),$$

(54)

where $N_n$ is a normalization constant. The charge density $J^\rho (41)$ dictates that $\phi_1$ must be normalized as

$$\frac{|E|}{M} \int_0^\infty dr |\phi_1|^2 = 1,$$  

(55)

so that, the normalization constant can be written as

$$N_n = \sqrt{\frac{2M\lambda^{m_\alpha} + 1}{|E| \Gamma(|m_\alpha| + n + 1)}}.$$

(56)

with $|E| \neq 0$. Moreover, the requirement $a = -n$ (quantization condition) implies into

$$E = \pm \sqrt{M^2 + k_z^2 + 2M\omega \left( 2n + \frac{|m|}{\alpha} \right)}.$$  

(57)

This last result shows that the discrete set of DKP energies are symmetrical about $E = 0$ and it is irrespective to the sign of $n$. This fact is associated to that DKP oscillator embedded in a magnetic cosmic string background does not distinguish particles from antiparticles. At this stage, due to invariance under rotation along the z-direction, without loss of generality we can fix $k_z = 0$. In general, $|E| > M$ excepts for $\omega = 0$ that the spectrum acquiesces $|E| = M$.

Now, let us consider the weak-coupling limit, $\omega \ll 1$ and $|E| \simeq M$ for small quantum numbers. With all, the Eq. (57) becomes

$$|E| \simeq M \left[ 1 + \omega \left( 2n + \frac{|m|}{\alpha} \right) \right].$$

(58)

note that due to equally spaced energy spectrum we can say that it describes a genuine DKP oscillator. But, as the weak-coupling limit does not correspond to the nonrelativistic limit, we also can consider the nonrelativistic limit of (57). Following the standard procedure, $E = M + \mathcal{E}$ with $M \gg \mathcal{E}$, and after some calculations one has that

$$\mathcal{E} \simeq \omega \left( 2n + \frac{|m|}{\alpha} \right).$$

(59)

which describes the energy of a traditional nonrelativistic harmonic oscillator.

Figures 1 and 2 illustrate the profiles of the energy as a function of $\omega$ for $|m| = 1$ and $|m| = 3$, respectively. In both figures we consider the three first quantum numbers and three different values for $\alpha$. From figures 1 and 2 one sees that all the energy levels emerge from the positive (negative)-energy continuum so that it is plausible to identify them with particle (antiparticle) levels. Furthermore, it is noticeable from both of these figures that for positive-energy spectrum one finds that the lowest quantum numbers correspond to the lowest eigenenergies, as it should be for particle energy levels. On the other hand, for negative-energy spectrum presents a similar behavior but the highest energy levels are labeled by the lowest quantum numbers and are to be identified with antiparticle levels. Also, one can see that for fixed values of $n$ and $|m|$, the energy $|E|$ increases as $\alpha$ decreases.
In Fig. 3, we illustrate the results of $|\phi_1|^2$ for $n = 0$, $|m| = 1$ and different values of $\alpha$. From figure 3 one can see that for fixed values of $n$ and $|m|$, the distribution has a maximum at $r \approx 1.7$ for $\alpha = 1$, this maximum decreases and moves to positive $r$-direction as $\alpha$ increases. In addition, comparison between $|\phi_1|^2$ shows that $\alpha = 1$ tends to be better localized than $\alpha < 1$. From this, we can conclude that in the limit $\alpha \to 0$ one has $N_n \to 0$, so that the solution $\phi_1$ tend to disappear one after another as $\alpha \to 0$. Fig. 4 illustrates the behavior of $|\phi_1|^2$ for $n = 2$, $|m| = 1$ and $\alpha = 0.5$. One can see that scalar bosons tend to be better localized at the blue region.

**5 Conclusions**

We studied the Duffin-Kemmer-Petiau (DKP) equation in a curved space-time and we found the general condition on the interactions which leads to a conserved current. This result is a generalization of [27] (Minkowski space-time). Furthermore, we showed that considering a magnetic cosmic string background and a DKP oscillator interaction, they furnish a conserved current.

Considering only scalar bosons, we showed that the motion equation which describes the quantum dynamics of a DKP oscillator in a magnetic cosmic string background was mapped into a Schrödinger-like equation embedded in a three-dimensional harmonic oscillator for the first component of the DKP spinor and the remaining components were expressed in terms of the first one in a simple way. Our result is very similar to Dirac oscillator in a magnetic cosmic string background, except by the absence of some terms that depend on the spin projection parameter [46].

We found the spectrum of energy for this background and we showed that the energy $|E|$ increases as $\alpha$ decreases. Both particle and antiparticle energy levels are members of the spectrum, and the particle and antiparticle spectra are symmetrical about $E = 0$. That fact implies that there is no channel for spontaneous boson-antiboson creation. We also found that both, weak-coupling limit and nonrelativistic limit furnish equally spaced energy spectrum, so that we concluded that this problem describes a genuine DKP oscillator.

The behavior of the solutions for this problem was discussed in detail. We showed that the magnetic cosmic string background influences on the scalar bosons localization. As an important result, we showed that
\(\alpha = 1\) tends to be better localized than \(\alpha < 1\) (see Fig. 3). Also, we showed that in the limit \(\alpha \to 0\) the solution \(\phi_1\) tends to disappear.
