Abstract

We perform a general reduction of an M5-brane on a spacetime that admits a null Killing vector, including couplings to background 4-form fluxes and possible twisting of the normal bundle. We give the non-abelian extension of this action and present its supersymmetry transformations. The result is a class of supersymmetric non-lorentzian gauge theories in 4+1 dimensions, which depend on the geometry of the six-dimensional spacetime. These can be used for DLCQ constructions of M5-branes reduced on various manifolds.

1 Introduction

The M5-brane is an interesting and important object in M-Theory for a variety of reasons. Its dynamics are described by a six-dimensional field theory with $(2,0)$ supersymmetry. For multiple M5-branes this is an interacting, strongly coupled superconformal field theory. However we currently lack a satisfactory understanding of this theory. Nevertheless a particularly fruitful application of M5-branes involves compactifying them on a manifold to obtain lower dimensional field theories. In this way many novel field theories have been identified as well as relations/dualities between them.

Recently we have studied null reductions of the M5-brane (a related abelian construction already appeared in [1] as well as in newer work [2]). In the simplest cases this leads to the construction of novel non-abelian field theories in (4+1)-dimensions with 24 (conformal) supersymmetries [3, 4]. Due to the fact that one has fixed a particular null direction in the six-dimensional theory, the Lorentz group has been reduced from $SO(1,5)$ to $SO(4)$. However, they still admit a large bosonic spacetime symmetry, including a Lifshitz scaling, coming from the six-dimensional conformal group [5]. In this paper we extend this discussion to general null reductions of the M5-brane on a curved manifold.

Non-Lorentzian theories with Lifshitz scaling have received a great deal of attention, primarily from the perspective of their AdS dual geometry (for a review see [6]). While some supersymmetric Lifshitz theories have been explicitly constructed (for example see [7, 8]) these often involve higher derivative terms, as is common in condensed matter systems. In contrast the field theories we obtain do not have higher derivatives but involve Lagrange multiplier constraints that reduce the dynamics to motion on a moduli space of anti-self-dual gauge fields [9, 10], in line with the DLCQ description of the M5-brane [11, 12]. Other classes of theories without Lorentz invariance but related to String/M-Theory have recently received attention in works such as [13–18].

Thus these more general null reductions should provide DLCQ-type descriptions of the field theories obtained by reducing M5-branes on other manifolds such as the Gaiotto theories [19]. Since there is no six-dimensional action based on non-abelian fields, the standard construction is to reduce the abelian theory and then find a suitable non-abelian extension that is compatible with supersymmetry. For example this was performed in [20] for the case of a general spacelike circle fibration. This was then followed by [21], who generalised this construction to include additional non-dynamical supergravity background fields. In this paper we will apply these constructions to the case of a null reduction. Although conceptually similar, reduction on a null direction is technically distinct and involves some interesting features. We will not consider the full background supergravity fields that were discussed in [21] however we will extend our results to backgrounds coming from fluxes in M-theory and a non-trivial connection on the normal bundle.

This paper is organised as follows. In section two we perform the general reduction of the abelian $(2,0)$ theory equations on a general spacetime with a null isometry. While the $(2,0)$ theory is based on a tensor multiplet, upon reduction we obtain vector fields. We then generalise the resulting action to a supersymmetric non-abelian gauge theory in
section three. In section four we examine some special cases of the general reduction, and in section five we include couplings to background flux terms. Section six contains our conclusions and comments. Our conventions are summarised in the appendix, along with some formulae for the geometry.

2 The Abelian Dimensional Reduction

In this section we will reduce the equations of motion and supersymmetry variations of the abelian (2,0) tensor multiplet on a six-dimensional manifold with metric \( \hat{g}_{MN} \) which admits a null Killing direction \( \hat{k}^M \). We will use hats to denote six-dimensional geometrical objects throughout.

2.1 The Background

Consider a fixed curved background, i.e. there is no back-reaction on the metric from the matter fields. We will further only consider six-dimensional Lorentzian manifolds which admit a null killing vector field

\[
\hat{k} = \frac{\partial}{\partial x^+}.
\]

In coordinates adapted to this isometry, \((x^+, x^-, x^i) i \in \{1, \ldots, 4\}\) it can be shown that the metric takes the general form (see also [22])

\[
\hat{g}_{MN} = \begin{pmatrix}
0 & -1 & -u_j \\
-1 & -2\sigma & -v_j - 2\sigma u_j \\
-u_i & -v_i - 2\sigma u_i & g_{ij} - 2u_i(v_j) - 2\sigma u_iu_j
\end{pmatrix}.
\]

Here \(g_{ij}\) is a Euclidean signature metric of a four-dimensional submanifold of the full six-dimensional spacetime. All components of \(\hat{g}_{MN}\) are allowed to depend on \(x^-\) and \(x^i\). The metric component \(g_{+-} = -1\) has been fixed using a suitable choice of the coordinate \(x^-\). This somewhat contrived choice of metric was chosen as it leads to the simpler inverse metric

\[
\hat{g}^{MN} = \begin{pmatrix}
|v|^2 + 2\sigma & u \cdot v - 1 & -v^j \\
\frac{u \cdot v - 1}{|u|^2} & |u|^2 & -u^j \\
-v^i & -u^i & g^{ij}
\end{pmatrix}.
\]

It is important to note that this geometry is distinct from that invoked in [23], in which a spacelike circle is infinitely Lorentz boosted. Even if limits are examined carefully in that paper, one finds as the boost parameter goes to zero the length of the Killing vector is always positive. In contrast our Killing vector has length zero, as would be expected from a null reduction.

For the time being we do not consider any other background fields other than the metric, in section 5 off-brane fluxes are added.
2.2 Tensor Multiplet

The six-dimensional abelian \( \mathcal{N} = (2,0) \) tensor multiplet contains a self-dual 3-form,

\[
H = \hat{\ast} H ,
\]

(2.4)

along with five scalar fields, \( X^I \), and a symplectic Majorana-Weyl spinor \( \psi \). These fields transform in the trivial, fundamental, and spinor representations of the \( R \)-symmetry group \( SO(5) \) (or equivalently \( USp(4) \)) respectively.

The supersymmetry transformations

\[
\begin{align*}
\delta X^I &= i \bar{\epsilon} \hat{\Gamma}^I \psi \\
\delta H_{MNP} &= 3i \partial_M (\bar{\epsilon} \hat{\Gamma}_{NP} \psi) \\
\delta \psi &= \hat{D}_M X^I \hat{\Gamma}^M \hat{\Gamma}^I \bar{\epsilon} + \frac{1}{2 \cdot 3!} H_{MNP} \hat{\Gamma}^{MNP} \epsilon ,
\end{align*}
\]

(2.5)

close up to the equations of motion:

\[
\begin{align*}
H &= \hat{\ast} H , & \hat{d} H &= 0 , & \hat{D}^M \hat{D}_M X^I &= 0 , & \hat{\Gamma}^M \hat{D}_M \psi &= 0 .
\end{align*}
\]

(2.6)

Here the supersymmetry parameter \( \epsilon \) has opposite chirality under \( \hat{\Gamma}_{012345} \) to \( \psi \), we make the choice \( \hat{\Gamma}_{012345} \epsilon = \epsilon \) and \( \hat{\Gamma}_{012345} \psi = -\psi \).

2.3 Reducing \( H = \hat{\ast} H \)

Let us first define the (4+1)-dimensional fields:

\[
F_{ij} = H_{ij} , \quad F_{i-} = H_{i-} , \quad G_{ij} = H_{ij} .
\]

(2.7)

In a trivial geometry these three fields are the independent components of the six-dimensional 3-form \( H \), and \( F \) and \( G \) satisfy simple (anti-)self-duality constraints. Our task here is to see the implications of the six-dimensional self-duality condition for a general background.

In what follows we use the geometrical quantities associated to the four-dimensional manifold with metric \( g_{ij} \). In particular we define the fields \( F^{ij} \), \( G^{ij} \) and \( F^i_- \) to have their indices raised by \( g^{ij} \). We also take

\[
\varepsilon_{+ijkl} = \varepsilon_{ijkl} ,
\]

(2.8)

with \( \varepsilon_{1234} = 1 \). Along with the metric \( g_{ij} \), this allows us to define a four-dimensional Hodge star operator \( \ast \). To proceed it is convenient to work with forms, we define the one forms \( v = v_i dx^i \), \( u = u_i dx^i \) and \( F_- = F_{i-} dx^i \), as well as the two forms \( F = \frac{1}{2} F^{ij} dx^i \wedge dx^j \) etc.. We also define the 3-form \( H = \frac{1}{3!} H_{ijkl} dx^i \wedge dx^j \wedge dx^k \).

Written in forms the self-duality condition on \( F_- \) is

\[
F_- = \ast (v \wedge u \wedge F_-) + \ast (v \wedge F) + \ast (u \wedge G) - \ast H .
\]

(2.9)
Applying $\star$ allows us to solve for $H$

$$H = \star F_\varepsilon + v \wedge u \wedge F_\varepsilon + v \wedge F + u \wedge G .$$

Eliminating $H$ from the other relations we create two equations that depend only on $F_\varepsilon, F, G$ along with the background fields $\sigma, u, v$ and $g$. In particular we find

$$F = - \star F + F_\varepsilon \wedge u + \star (F_\varepsilon \wedge u)$$
$$G = \star G - 2\sigma \star F - F_\varepsilon \wedge v + \star (F_\varepsilon \wedge v) + 2\sigma \star (F_\varepsilon \wedge u) .$$

Defining

$$\mathcal{F} = F - F_\varepsilon \wedge u$$
$$\mathcal{G} = G - \sigma F - F_\varepsilon \wedge (v + \sigma u) ,$$

these expressions simplify further to

$$\mathcal{F} = - \star \mathcal{F}$$
$$\mathcal{G} = \star \mathcal{G} .$$

2.4 Decomposing $\hat{d}H = 0$

The exterior derivative is metric independent, so the results will hold for all backgrounds. In components

$$\partial_{[MN]PQ} H = 0 .$$

Our construction has a $x^+$ isometry, so all fields are independent of $x^+$. This gives an expression for each of the combinations of indices $-ij, +ijk, -ijk, ijk$

$$\partial_{[+} H_{-ij]} = 0 \implies \partial_- F + dF_\varepsilon = 0$$
$$\partial_{[+} H_{ijk]} = 0 \implies dF = 0$$
$$\partial_{[-} H_{ijk]} = 0 \implies dG = \partial_- H$$
$$\partial_{[i} H_{jkl]} = 0 \implies dH = 0 .$$

Where we have written the 4 dimensional exterior derivative as $d$. The first and second expressions can be combined to give a simple five-dimensional Bianchi identity

$$d(5) F(5) = 0 , \quad F(5) = F + F_\varepsilon \wedge dx^- .$$

Implying that locally there exists $(A_\varepsilon, A_i)$ such that

$$F_{ij} = \partial_i A_j - \partial_j A_i , \quad F_{\varepsilon} = \partial_\varepsilon A_\varepsilon - \partial_- A_i .$$

The equations for $\mathcal{G}$ and $\mathcal{F}$ become

$$d(\mathcal{G} + \sigma \mathcal{F} - F_\varepsilon \wedge v) = \partial_- (\star F_\varepsilon + v \wedge u \wedge F_\varepsilon + v \wedge F + u \wedge (\mathcal{G} + \sigma \mathcal{F} - F_\varepsilon \wedge v))$$
$$d(\star F_\varepsilon + v \wedge u \wedge F_\varepsilon + v \wedge F + u \wedge (\mathcal{G} + \sigma \mathcal{F} - F_\varepsilon \wedge v)) = 0 .$$
Using the duality properties of $F$ and $G$ we can rewrite these equations in component form as
\[ D_j G^{ij} + D_j (\sigma \star F^{ij}) - D_j (\star (F_- \wedge v)^{ij}) + D_- F^i_- - D_- (\star F^{ij} v_j) - D_- (\sigma \star F^{ij} u_j) - D_- (G^{ij} u_j) = 0 \]
\[ -D_i F^i_+ + D_i (\star F^{ij} v_j) + D_i (G^{ij} u_j) + D_i (\sigma \star F^{ij} u_j) = 0, \quad (2.19) \]
respectively.

### 2.5 An Action

Lastly we wish to construct an action that reproduces these equations of motion, along with those of the scalars and fermions. In the latter cases a six-dimensional action already exists which can be trivially reduced to find an appropriate five-dimensional action.

Somewhat remarkably the equations for $F_-, F$ and $G$ can be derived from a Lagrangian density on a four-dimensional manifold with Euclidean signature, whose fields also depend on the ‘time’ coordinate $x^-$. To this end we assume that $F_-$ and $F$ arise from a potential $(A_-, A_i)$ as in (2.17). However we do not impose a potential for $G$ but rather impose $G = \star G$. Some trial and error shows that the equations motion (2.19) then arise from the lagrangian
\[ L_H = \frac{1}{2} \star F_- \wedge F_- - \frac{1}{4} \sigma \star F \wedge F + \frac{1}{2} F \wedge G - \frac{1}{2} F \wedge F_- \wedge v. \quad (2.20) \]

Where
\[ F_{ij} = \partial_i A_j - \partial_j A_i \]
\[ F_{i-} = \partial_i A_- - \partial_- A_i \]
\[ F_{ij} = F_{ij} + u_i F_{j-} \]
\[ G_{ij} = \frac{1}{2} \sqrt{g} \varepsilon_{ijkl} G^{kl}, \quad (2.21) \]
and the $k, l$ indices are raised with respect to $g^{ij}$. Variation with respect to $G$ immediately gives the anti-self-dual condition $F = - \star F$. On the other hand varying $A_i$ and $A_-$ give (2.19) respectively.

Inclusion of the scalars and fermions is easier, as there is a Lagrangian formulation for the free conformal case in any dimension;
\[ L_{matter} = -\sqrt{-g} \left( \frac{1}{2} g^{MN} \partial_M X^I \partial_N X^I + \frac{1}{8} \frac{d-2}{d-1} R X^I X^I - \frac{i}{2} \bar{\psi} \Gamma^M \hat{D}_M \psi \right). \quad (2.22) \]

\[ ^1 \text{Note that this is a legitimate imposition, as self-dual tensors are an irreducible representation of the Lorentz group in even dimension} \]
Performing the reduction by assuming $\partial_+ = 0$, and inserting $d = 6$, we find

$$L_{\text{matter}} = - \sqrt{g} \left( \frac{1}{2} \partial_i X^I \partial^i X^I - \frac{1}{2} |u|^2 \partial_+ X^I \partial_- X^I + u^i \partial_i X^I \partial_+ X^I - \frac{1}{10} \hat{R} X^I X^I ight) + i \frac{1}{2} \bar{\psi} \hat{\Gamma}^- \hat{D}_- \psi + i \frac{1}{2} \bar{\psi} \hat{\Gamma}^i \hat{D}_i \psi + \frac{1}{2} i \bar{\psi} \hat{M} \psi \right),$$

(2.23)

where

$$\hat{M} = \frac{1}{4} \hat{\Gamma}^+ \hat{\omega}_{+MN} \hat{\Gamma}^{MN}$$

$$= \frac{1}{4} \partial_- u_i \hat{\Gamma}^+ \hat{\Gamma}^{-i} + \frac{1}{4} \partial_i u_j \hat{\Gamma}^+ \hat{\Gamma}^{ij}.$$  

(2.24)

Note that we have kept the fermionic terms and $\hat{R}$ in their six-dimensional form. In principle these can be computed from the expression (6.11), (6.13) and (6.6) found in the appendix. However expanding everything out in full detail for a general background leads to rather unwieldy expressions. Rather, we will provide more explicit expressions in various special cases below.

It is helpful to introduce

$$\nabla_i = \partial_i - u_i \partial_-,$$  

(2.25)

This derivative generally has torsion;

$$\nabla_i \nabla_j X^I = -2 \nabla_{[i} u_{j]} \partial_- X^I.$$  

(2.26)

One also finds that

$$\nabla_{[i} F_{jkl]} = 0.$$  

(2.27)

Putting all these together we can write the full abelian action as

$$S = \frac{1}{g^{YM}} \int dx^{-d^4} x \sqrt{g} \left\{ \frac{1}{2} F_{i-} F^i_- - \frac{1}{4} \sigma F_{ij} \mathcal{F}^{ij} + \frac{1}{2} G_{ij} \mathcal{F}^{ij} - \frac{1}{2} \sqrt{g} \varepsilon^{ijkl} F_{i-} v_j F_{kl} - \frac{1}{2} \nabla_i X^I \nabla^i X^I - \frac{1}{10} \hat{R} X^I X^I + \frac{1}{2} i \bar{\psi} \Gamma^- \hat{D}_- \psi + \frac{1}{2} i \bar{\psi} \hat{\Gamma}^i \hat{D}_i \psi + \frac{1}{2} i \bar{\psi} \hat{M} \psi \right\}.$$  

(2.28)

### 3 Supersymmetry and Non-Abelian Generalization

Next we want to show that the action (2.28) is supersymmetric. To this end we assume there exists a solution to the conformal Killing spinor equation

$$\hat{D}_M \epsilon = \hat{\Gamma}_M \eta,$$  

(3.1)

with $\partial_+ \epsilon = 0$. In particular this implies

$$\hat{D}_+ \epsilon = \frac{1}{4} \hat{\omega}_{+MN} \hat{\Gamma}^{MN} \epsilon = \hat{\Gamma}_+ \eta,$$  

(3.2)
which is a further condition that we must impose on the geometry. As it stands the action (2.28) is not invariant under the transformations that follow directly from (2.5). One problem is that the variation $\delta G_{ij}$ obtained from (2.5) is not self-dual off-shell. Thus we must adjust the algebra in a way that ensures $\delta G_{ij}$ is self-dual.

A deeper issue is that although we impose the isometry $\partial_+ \psi = 0$, this does not imply that $\hat{D}_+ \psi = 0$. For the bosonic fields this distinction does not cause a problem as both $X^I$ and $H_{MNP}$ do not couple to the spacetime connection (due to the fact that $H_{MNP}$ is anti-symmetric). But for $\psi$ this leads to the Scherk-Schwarz-like mass term $\frac{i}{2} \bar{\psi} \hat{M} \psi$ in (2.28).

On-shell this is also not a problem as $\delta H_{MNP}$ in (2.5) contains terms involving $\hat{D}_+ \psi$ which lead to the closure of the algebra and invariance of the equations of motion. However we find that the $\bar{\psi} \hat{M} \psi$ term can only be made supersymmetric in general by modifying the variation of $F_{ij}$ and $F_{-i}$ in a way that means they are no longer closed. This in turn implies that a suitable expression for the supersymmetry variation of the gauge field cannot be defined. Since the existence of such a gauge field was crucial for the construction of the action, having no definable variation is not tenable.

Alternatively one might question why we start with the supersymmetry algebra (2.5) and not simply

\begin{align*}
\delta X^I &= i \bar{\hat{\Gamma}}^I \psi \\
\delta B_{MN} &= 2i \bar{\hat{\Gamma}}_{MN} \psi \\
\delta \psi &= \hat{D}_M X^I \hat{\Gamma}^M \hat{\Gamma}^I \epsilon + \frac{1}{2 \cdot 2!} \partial_M B_{NP} \hat{\Gamma}^{MNP} \epsilon ,
\end{align*}

identify $H = dB$ and impose $H = \hat{*} H$ as an equation of motion. However in this case one finds that $G_{ij} = 2 \partial_+ B_{ij} + \partial_- B_{ij}$ and hence imposing an off-shell self-duality constraint on $G_{ij}$ and $\delta G_{ij}$ becomes non-trivial.

Thus to obtain a supersymmetric action after reduction on $x^+$ we find ourselves in a balancing act of finding off-shell expressions for $\delta A_-$, $\delta A_i$ and $\delta G_{ij} = \star \delta \tilde{G}_{ij}$ when $\hat{D}_+ \psi \neq 0$.

### 3.1 Correcting $\delta \tilde{G}$

The next problem is that $\delta \tilde{G}$ is not self-dual off shell but to write the action we require that $\tilde{G}$ is self-dual. A short calculation shows that

$$
\delta G_{ij} - \star \delta G_{ij} = i \bar{\hat{\Gamma}}_{-i} E(\psi) ,
$$

where $E(\psi)$ denotes the fermion equation of motion. Therefore we simply shift $\delta G_{ij} \rightarrow \delta' G_{ij} = \delta G_{ij} - \frac{1}{2} i \bar{\hat{\Gamma}}_{-i} E(\psi)$, resulting in

\begin{align*}
\delta' G_{ij} - \star \delta' G_{ij} &= \delta G_{ij} - \frac{1}{2} i \bar{\hat{\Gamma}}_{-i} E(\psi) - \star (\delta G_{ij} - \frac{1}{2} i \bar{\hat{\Gamma}}_{-i} E(\psi))) = 0 ,
\end{align*}

relabelling $\delta' G_{ij}$ to $\delta G_{ij}$ gives us a self-dual $\delta \tilde{G}$. 

8
Next the $F_{ij}F^{ij}$ term, not present in the flat theory, must be accounted for in the supersymmetry transformations. We must use properties of $F_{ij}$ to shift $\delta G_{ij}$ in such a way to cancel the effects of this new term, whilst ensuring $\delta G_{ij}$ remains self-dual.

It is useful to note that a fermionic term of definite duality, e.g. $\bar{\psi} \Gamma + \Gamma_{ij} \psi$, can be used to build other terms of either the same or opposite duality (see Appendix A for origin of these dualities). For instance inserting an additional $\Gamma_k$ will result in either a term of the same duality; $\bar{\psi} \Gamma + \Gamma_{ij} \Gamma_k \psi$, or opposite duality; $\bar{\psi} \Gamma + \Gamma_{ij} \Gamma_k \psi$. Furthermore we have the identity $\hat{\nabla}_i F_{jk} = 0$, allowing us to shift $\delta G_{ij}$ by any amount proportional to $\Gamma_{ijk} \hat{\nabla}_k \psi$ so that $\delta L$ shift by a total derivative. With this in mind we choose the shift

$$\delta G_{ij} \rightarrow \delta G_{ij} + i \bar{\psi} \sigma \Gamma_{ij} \Gamma_k \hat{\nabla}_k \psi ,$$

which is self-dual by construction. A simple Gamma matrix manipulation shows the overall change to $\delta L$

$$\delta L \rightarrow \delta L + \frac{1}{2} F^{ij} (i \bar{\psi} \sigma \Gamma_{ij} \hat{\nabla}^k \psi + 2 i \bar{\psi} \sigma \Gamma_{ij} \hat{\nabla}_j \psi)$$

(3.7)

By the modified Bianchi identity (2.27) for $F$ under $\nabla$, the first term is a total derivative so does not contribute. The shift (3.6) therefore cancels the term $-\frac{1}{2} \sigma \delta F_{ij} F^{ij}$. Note that $\delta G_{ij}$ also has a term proportional to $\eta$, to account for terms arising from integration by parts.

Our corrected supersymmetry transformations read

$$\delta X^I = i \bar{\epsilon} \Gamma^I \psi$$
$$\delta A_i = -i \bar{\epsilon} (\Gamma^- u_i + \Gamma^+ i) \psi$$
$$\delta A_- = -i \bar{\epsilon} \Gamma^- \psi$$
$$\delta G_{ij} = -\frac{1}{2} i \bar{\epsilon} \Gamma^+ \Gamma^- \Gamma_{ij} D_- \psi - \frac{1}{2} i \bar{\epsilon} \Gamma^+ \Gamma_{ij} \hat{\nabla}^k \psi + i \bar{\epsilon} \sigma \Gamma^+ \Gamma_{ij} \Gamma^k \psi - 3i \bar{\eta} \Gamma^+ \Gamma_{ij} \psi$$
$$\delta \psi = -F_{i-} \Gamma^{+i} \epsilon + \frac{1}{4} F_{ij} \Gamma^{+ij} \epsilon + \frac{1}{4} G_{ij} \Gamma^{-ij} \epsilon - \Gamma^i \hat{\nabla}_i \hat{\nabla}^j X^j \epsilon + \Gamma^i \Gamma^j \hat{\nabla}_i \hat{\nabla}_j X^j \epsilon - 4X^I \Gamma^I \eta .$$

(3.8)

Again we have kept many of the fermionic terms in their six-dimensional form for notational simplicity. With these supersymmetry transformations we find that the action (2.28) is invariant up to terms arising from the $\bar{\psi} \hat{M} \psi$ term. In other words we find $\delta S = 0$ if

$$\delta \bar{\psi} \hat{M} \psi = 0 .$$

(3.9)

The implications of this constraint are explained in section 4.1.

### 3.2 Non-Abelian Theory

Our next task is to find a non-abelian extension of the abelian action found above which remains supersymmetric. After some trial and error we find that, assuming (3.9) holds,
non-abelian extension is
\[
S = \frac{1}{g_{YM}^2} \text{tr} \int dx^6 d^4 x \sqrt{-g} \left( \frac{1}{2} F_{i-} F_{i-} - \frac{1}{4} \sigma F_{ij} F^{ij} + \frac{1}{2} G_{ij} F^{ij} - \frac{1}{2 \sqrt{g}} \epsilon^{ijkl} F_{i-} v_j F_{kl} 
- \frac{1}{2} \nabla_i X^1 \nabla^i X^1 - \frac{1}{10} \hat{R} X^I X^I + \frac{i}{2} \tilde{\psi} M \psi + \frac{1}{2} i \tilde{\psi} \Gamma^i \psi + \frac{1}{2} \tilde{\psi} \Gamma_i \Gamma^I [X^I, \psi] \right),
\]
where all the fields now live in the adjoint of some gauge group. The supersymmetry transformations are
\[
\begin{align*}
\delta X^I &= i \epsilon \Gamma^I \psi \\
\delta A_i &= -i \tilde{\epsilon} (\Gamma_{+} u_i + \Gamma_{+} i) \psi \\
\delta A_- &= -i \tilde{\epsilon} \Gamma_{+} \psi \\
\delta G_{ij} &= -\frac{1}{2} i \tilde{\epsilon} \Gamma_{+} \Gamma_{-} \Gamma_{ij} \hat{D}_{-} \psi - \frac{1}{2} i \tilde{\epsilon} \Gamma_{+} \Gamma_{-} \Gamma_{ij} \hat{\nabla}_{k} \psi + i \tilde{\epsilon} \sigma \Gamma_{+} \Gamma_{ij} \Gamma_{k} \hat{\nabla}_{k} \psi \\
&\quad - \frac{i}{2} \tilde{\epsilon} \Gamma_{ij} \Gamma^{I} \Gamma_{+} \Gamma_{-} [X^I, \psi] - 3i \eta \Gamma_{-} \Gamma_{ij} \psi \\
\delta \psi &= -F_{-} \Gamma_{+} \psi + \frac{1}{4} F_{ij} \Gamma_{+} \psi + \frac{1}{4} G_{ij} \Gamma_{-} \psi + \Gamma_{+} \Gamma_{-} \Gamma_{ij} \psi + \Gamma_{+} \Gamma_{-} \hat{\nabla}_{i} X^I \psi
+ \frac{i}{2} \Gamma_{+} \Gamma_{-} \psi [X^I, X^I] \psi - 4X^I \Gamma^I \eta,
\end{align*}
\]
where again we have left \( \hat{R} \) and the fermion derivatives in their six-dimensional form.

### 3.3 Twisting

We can also introduce an non-zero connection on the R-symmetry of the form
\[
\hat{D}_M X^I = \hat{\partial}_M X^I + \hat{A}_M (X^I)
\]
\[
\hat{\partial}_M \psi = \hat{D}_M \psi + \frac{1}{4} \hat{\Omega}_M^{IJ} \Gamma^{IJ} \psi,
\]
where $\hat{\mathcal{R}}_{IJ}^{MN}$ is the curvature of $\hat{\Omega}_{IJ}^{MN}$. Thus to obtain a supersymmetric reduction we must ensure $\hat{D}_M \epsilon = \hat{\Gamma}_M \eta$, $\partial_+ \epsilon = 0$ and arrange for suitable choices of curvature and $T^{IJ}$ so that the terms in $\delta S_{\text{matter}}$ cancel. Indeed the usual role of twisting is to allow for solutions to $\hat{D}_M \epsilon = 0$ on manifolds with non-vanishing curvature. For example in the case of a Riemann surface along $x^3, x^4$ with normal directions $X^6, X^7$ the first term vanishes and we can arrange to cancel the last two by taking

$$T^{67} = \mp \frac{3}{5} \hat{\mathcal{R}}_{34}^{67}, \quad (3.15)$$

and projecting on to spinors with $\hat{\Gamma}_{34} \hat{\Gamma}^{67} \epsilon = \pm \epsilon$, where the sign is chosen to correspond to solutions of $\hat{D}_M \epsilon = 0$.

4 Examples

In the previous section we constructed the non-abelian extension of the reduced M5-brane equations and their supersymmetry transformations. We left the fermion terms in a six-dimensional form as the complete expression in full generality is quite complicated and unenlightening. In this section we will evaluate some general classes of examples explicitly.

4.1 Obstruction from $\hat{M}$

In order to obtain a supersymmetric reduction we require in addition that $(3.9)$, i.e. $\delta \bar{\psi} \hat{M} \psi = 0$, is satisfied. In addition the condition $(3.2)$ ensures that

$$\frac{1}{4} \partial_- u_i \Gamma^{-i} \epsilon_- + \frac{1}{4} (\partial_i u_j - u_i \partial_- u_j) \Gamma^{ij} \epsilon_+ = \Gamma_+ \eta$$

$$\partial_i u_j \Gamma^{ij} \epsilon_- = 0. \quad (4.1)$$

We do not propose to give the general solutions to these conditions which place various restrictions on both $\epsilon$ and the background fields $\sigma, u, v$. For example if $du$ is not anti-self-dual then the second equation implies that $\epsilon_- = 0$.

Since there are no mass terms for the scalars (beyond the usual conformal coupling to the curvature) a physically well-motivated class of background that ensures $(3.9)$ are those for which there is also no mass term for the fermions:

$$\bar{\psi} \hat{M} \psi = 0. \quad (4.2)$$

This leads to the following conditions on the background fields

$$du - u \wedge \partial_- u = - \ast (du - u \wedge \partial_- u)$$

$$\partial_- u = -2i_v (du - u \wedge \partial_- u)$$

$$\sigma (du - u \wedge \partial_- u) = \frac{1}{2} (1 - \ast) (v \wedge \partial_- u). \quad (4.3)$$
With $i_v(\cdot)$ denoting contraction with $v$. There are two natural solutions to these constraints:

$$\begin{align*}
\text{case 1: } u \neq 0, \partial_- u = 0 & \implies v = \sigma = 0, \ dy = - \star du \\
\text{case 2: } u = 0, \ v, \sigma \neq 0 .
\end{align*}$$

(4.4)

Therefore from (4.1) we find

$$\begin{align*}
\text{case 1: } \epsilon_- \neq 0 & \quad \eta = -\frac{1}{8} \delta_{ij} \Gamma_{ij} \epsilon_+ \\
\text{case 2: } \eta = 0 .
\end{align*}$$

(4.5)

In what follows we will only focus on these two cases so that we can be as explicit as possible. We emphasize that other solutions to the constraints (3.2) and (3.9) might also be possible.

**4.2 Case 1:** $\partial_- u = v = \sigma = 0 \ dy = - \star du$

Here the action is

$$S = \frac{1}{g_{YM}^2} \int dx^- dt^i x \sqrt{g_\gamma^2 \frac{1}{2} F^2_i + \frac{1}{2} G_{ij} F_{ij} - \frac{1}{2} \nabla_i X'^I \nabla^i X'^I - \frac{1}{10} \hat{R} X'^I X'^I}$$

$$+ \bar{\psi} \Gamma_- \partial_- \psi - u_i \bar{\psi} \Gamma^i \partial_- \psi + \bar{\psi} \Gamma^I D_i \psi - \frac{1}{4} \epsilon_{[i} \partial_- e_{j]l} \bar{\psi} (\Gamma_- - u_k \Gamma^k) \Gamma^{ij} \psi \right\},$$

(4.6)

which is invariant under

$$\delta X'^I = i \epsilon \Gamma'^I \psi$$

$$\delta A_i = -i \epsilon (\Gamma_{++} u_i + \Gamma_{++}) \psi$$

$$\delta A_- = -i \epsilon \Gamma_{+-} \psi$$

$$\delta G_{ij} = i \epsilon \Gamma_{ij} \partial_- \psi_+ - \frac{1}{2} i \epsilon \Gamma_- \Gamma^k \Gamma_{ij} (D_k - u_k \partial_-) \psi - \frac{1}{2} i \partial_- g_{kl} \epsilon \Gamma^k \Gamma_{ij} \Gamma^l \psi_-$$

$$- \frac{1}{4} \epsilon_{[i} \partial_- e_{j]l} \bar{\psi} \Gamma_{ij} \Gamma^l \psi_+ - \frac{1}{8} \epsilon \Gamma_{ij} \partial_- e_{jl} u_p \epsilon \Gamma^p \Gamma_{ij} \Gamma^+ \Gamma^k \psi_+ - 3 i \epsilon \Gamma_- \Gamma_{ij} \psi$$

(4.7)

$$\delta \psi = -F_{ij} \Gamma^{+i} \epsilon + \frac{1}{4} F_{ij} \Gamma^{+ij} \epsilon + \frac{1}{4} G_{ij} \Gamma^{+ij} \epsilon + \Gamma_- \Gamma^I D_- X'^I \epsilon + \Gamma^i \Gamma^I \nabla_i X'^I \epsilon$$

$$+ \frac{i}{2} \Gamma^I \Gamma^I \left[ X'^I, X'^I \right] \epsilon - 4 X'^I \Gamma^I \eta .$$

For brevity we have left the six-dimensional Ricci scalar unexpanded, for completeness in terms of four-dimensional objects only this is

$$\hat{R} = R - \frac{1}{2} g^{ij} (\partial_\gamma \partial_- g_{ij} + \frac{1}{2} u^2 g^{kl} \partial_- g_{ik} \partial_- g_{jl} - g^{kl} \partial_- g_{ik} u_m \gamma^m_{ij})$$

$$- u^i (\partial_j g^{jk} \partial_- g_{ki} + g^{jk} \partial_- g_{kj} \gamma^l_{kl} - g^{jk} \partial_- g_{kl} \gamma^l_{kl} - \partial_- \gamma^j_{ij} + \frac{1}{2} \partial_i (g^{jk} \partial_- g_{jk})),$$

(4.8)

Note that in case 2 we could consider the the weaker conditions $du = 0$ and $\partial_- u = 0$. But this implies $u = df$ in which case we can set $u = 0$ by a diffeomorphism $x^- \rightarrow x^- + f$. 

12
with $\gamma^i_{jk}$ the Christoffel symbols of the 4d metric. In the specific case of this metric being independent of $x^+$ this reduces to

$$\hat{R} = R .$$

### 4.3 Case 2: $u = 0$

Here the action is

$$S = \frac{1}{g_{YM}} \int \, dx^4 \sqrt{g} \left( \frac{1}{2} F_i^- F_i^+ - \frac{1}{4} \sigma F_i^+ F_i^+ + \frac{1}{2} G_{ij} F^{ij} - \frac{1}{2} \sqrt{g} \varepsilon^{ijkl} F_{i,j} v_j F_{k,l} - \frac{1}{2} D_i X^i D^i X^i + \frac{1}{2} i\bar{\psi} \Gamma^--\psi + \frac{1}{2} i\bar{\psi} \Gamma^i D_i \psi - \frac{1}{4} (\partial_i v_j + \varepsilon_{ijk} \partial_- e_i j k_2) \bar{\psi} \Gamma^{-ij} \psi \right),$$

since $u$ is now zero $\mathcal{F} = F$. Note also that since $\eta = 0$, we have $\hat{D}_M \epsilon = 0$ and hence $\hat{R} = 0$. This action is invariant under the following transformations

$$\delta X^I = i\bar{\epsilon} \Gamma^I \psi$$
$$\delta A_i = -i\bar{\epsilon} (\Gamma_{+-} v_i + \Gamma_{+} \psi)$$
$$\delta A_- = -i\bar{\epsilon} \Gamma_{+-}$$

$$\delta G_{ij} = i\bar{\epsilon} \Gamma_{ij} \partial_- \psi_++ i\frac{1}{2} (\partial_- v_k - \partial_k \sigma) \varepsilon \Gamma_{ij} \Gamma^{-k} \psi_+ + \frac{1}{4} i (\partial_k v_l - \varepsilon_{kjl} e_i) \varepsilon \Gamma_{ij} \Gamma^{kl} \psi_+ - \frac{1}{2} i\bar{\epsilon} \Gamma_{--} \partial_- \psi_+ + \frac{1}{2} i (\partial_- v_l - \varepsilon_{kjl} e_i) \varepsilon \Gamma_{ij} \Gamma^{kl} \psi_+$$

$$\delta \psi = -F_{i,j} \Gamma^{ij} \epsilon + \frac{1}{4} F_i \Gamma^{+ij} \epsilon + \frac{1}{4} G_{ij} \Gamma^{-ij} \epsilon + \Gamma^i \Gamma^j D_- X^i \epsilon + \Gamma^i \Gamma^j D_+ X^j \epsilon$$

$$+ \frac{i}{2} \Gamma_+ \Gamma^IJ [X^I, X^J] \epsilon .$$

### 5 Flux Terms

In [21] the reduced M5-branes action is coupled to background supergravity fields such as a non-zero M-theory 4-form $\hat{G}_{\mu
u\rho\sigma}.$ The presence of such a flux leads to Myers-like terms in the M5-brane effective action. In addition the fluxes modify the Killing spinor condition to:

$$0 = \hat{D}_\mu \epsilon + \frac{1}{288} \left( \hat{G}_{\nu\lambda\rho\sigma} \hat{\Gamma}^{\nu\lambda\rho\sigma}_\mu + 8 \hat{G}_{\mu\lambda\rho} \hat{\Gamma}^{\nu\lambda\rho}_\mu \right) \epsilon .$$

We need to find fluxes that are compatible with the condition $\partial_+ \epsilon = 0$. In particular applying the condition $\partial_+ \epsilon = 0$ to (5.1) for the choice $\mu = +$ leads to a purely algebraic constraint. For simplicity we will restrict our attention here to cases where this constraint is trivial: i.e. $\hat{D}_+ \epsilon = 0$ and there is no contribution in (5.1) from the fluxes for $\mu = +$. Non-trivial cases arise in case 1 and require a cancellation between $\hat{D}_+ \epsilon$ and the fluxes or

---

3The authors of [21] use a $USp(4)$ notation where the flux terms are denoted by $S^{mn}$ and $T_{ab}^{mn}$ with $m, n = 1, 2, 3, 4$ and $a, b = 0, 1, 2, 3, 4, 5$. 

---

13
twisting (and perhaps including additional restrictions on $\epsilon$). These are better addressed on a case-by-case basis rather than our general discussion. Thus we restrict to case 2 ($u = 0$), where $\hat{D}_+\epsilon = \partial_+\epsilon = 0$ and we only consider constant fluxes of the form

$$\hat{G}_{\mu\nu\lambda} = C_{\mu\nu\lambda},$$

(5.2)

with $\mu, \nu, \lambda \neq +, -$. In particular we find the possibilities $C_{IJK}, C_{IJk}, C_{Ijk}$ and $C_{ijk}$. These are expected to lead to additional terms in the M5-brane effective action of the form:

$$S' \sim \frac{1}{g_{YM}^2} \text{tr} \int d^4x d^4\sqrt{g} \left( C^{IJK} X^I \Gamma_{+} X^J \Gamma_{L} + C^{ij} X^I F_{ij} \right) + C^{ijk} \left( A_i \partial_j A_k + \frac{2i}{3} A_i A_j A_k \right) - \frac{1}{2} m_{IJ}^2 X^I X^J + \frac{i}{2} \bar{\psi} m \psi, \quad (5.3)$$

where $m$ and $m_{IJ}$ are mass terms which are linear in the fluxes. Starting with a general ansatz we find the only the following corrections to the action can be made supersymmetric:

$$S' = \frac{1}{g_{YM}^2} \text{tr} \int d^4x d^4\sqrt{g} \left( \frac{1}{6} C^{ij} X^I F_{ij} + \frac{i}{144} \bar{\psi} \left( -\Gamma_+ C^{IJK} \Gamma_{-} C^{IJK} + 3 \Gamma_+ C^{ijk} \Gamma_{-} C^{ijk} \right) \psi \right). \quad (5.4)$$

Along with this there additional terms in the supersymmetry transformations: $\delta \rightarrow \delta + \delta'$ with

$$\delta' \psi = -\frac{1}{12} C^{JKL} \Gamma_{+} C^{JKL} \Gamma_{+} X^I \epsilon - \frac{1}{6} C^{JKL} \Gamma_{+} X^I \Gamma_{+} \epsilon$$

$$+ \frac{1}{3} C^{ijk} \Gamma_{+} \Gamma_{+} \Gamma_{+} \epsilon + \frac{1}{4} C^{ijk} \Gamma_{+} \Gamma_{+} X^I \epsilon$$

$$\delta' G_{ij} = -\frac{7i}{144} \bar{\psi} \Gamma_{+} \Gamma_{+} C^{IJK} \Gamma_{+} \epsilon + \frac{i}{12} (C^{I} + \ast C^{I})_{ij} \bar{\psi} \Gamma_{-} \Gamma_{+} \epsilon$$

$$- \frac{5i}{24} \bar{\psi} \Gamma_{-} \Gamma_{+} C^{Ikl} \Gamma_{kl} \Gamma_{ij} \epsilon - \frac{i}{48} \bar{\psi} \Gamma_{-} \Gamma_{+} C^{Ikl} \Gamma_{kl} \Gamma_{ij} \epsilon,$$

(5.5)

and furthermore the Killing spinor equation is also modified to

$$\hat{D}_{+} \epsilon = \frac{1}{72} C^{IJK} \Gamma_{+} \Gamma_{+} \Gamma_{+} \epsilon - \frac{1}{6} C^{i} C^{k} \Gamma_{+} \Gamma_{+} \epsilon - \frac{1}{24} C^{ijk} \Gamma_{+} \Gamma_{+} \epsilon$$

$$\hat{D}_{-} \epsilon = \frac{1}{72} C^{IJK} \Gamma_{+} \Gamma_{+} \Gamma_{+} \epsilon + \frac{1}{36} C^{IJK} \Gamma_{+} \Gamma_{+} \epsilon + \frac{1}{24} C^{ijk} \Gamma_{+} \Gamma_{+} \epsilon + \frac{1}{12} C^{ijk} \Gamma_{+} \Gamma_{+} \epsilon$$

$$\hat{D}_{+} \epsilon = 0, \quad (5.6)$$

which is in agreement with the eleven-dimensional supergravity Killing spinor equation (5.1).

At first glance our result is somewhat surprising: we find no supersymmetric corrections possible for fluxes of the form $C^{ijk}$ or $C^{IJK}$, no Myers-type flux term for $C^{IJK}$ and no bosonic mass terms at all. One way to see this strange behaviour is to note that the
null theory can be obtained from a non-Lorentzian rescaling of familiar five-dimensional Yang-Mills theory [24]. Here one makes the rescaling of space and time according to

\[ x^i \rightarrow \zeta^{-1/2} x^i, \quad x^0 \rightarrow \zeta^{-1} x^0, \tag{5.7} \]

and the matter fields by

\[ X^I \rightarrow \zeta X^I, \quad \psi_+ \rightarrow \zeta^{3/2} \psi_+, \quad \psi_- \rightarrow \zeta \psi_-, \tag{5.8} \]

and then takes the limit \( \zeta \rightarrow 0 \), this is equivalent to [23]. One then makes the identification \( x^- = x^0 \) (but note that \( \Gamma_- = (\Gamma_0 - \Gamma_5)/\sqrt{2} \)). The scaling of the supersymmetry parameter \( \epsilon \) is fixed by requiring the fields scale the same way as their supersymmetry variations, this leads to [24]

\[ \epsilon_+ \rightarrow \epsilon_+, \quad \epsilon_- \rightarrow \zeta^{-1/2} \epsilon_- . \tag{5.9} \]

Let us now consider the form of \( S' \) that would arise from a spacelike reduction of the M5-brane in a non-vanishing supergravity flux (e.g. as in [21]):

\[
S_{\text{SYM}}' \sim \frac{1}{g_{\text{YM}}^2} \text{tr} \int d^5x \sqrt{g} \left( C^{IJK} X^I [X^J, X^K] + C^{IJM} X^I D_M X^J + C^{IMN} X^I F_{MN} \right.
\]
\[ + C^{MNP} \left( A_M \partial_N A_P - \frac{2i}{3} A_M A_N A_P \right) - \frac{1}{2} m_{IJ}^2 X^I X^J + i \bar{\psi} m \psi \right) , \tag{5.10} \]

where again \( m_{IJ} \) and \( m \) are linear in the fluxes. Examining the Killing spinor equation (5.1) one sees that we must scale the fluxes according to

\[ C_{\mu \nu \lambda} \rightarrow \zeta^{-1} C_{\mu \nu \lambda} , \tag{5.11} \]

otherwise we encounter divergences or the fluxes are scaled away. As a result, the deformed action scales as, schematically,

\[
S_{\text{SYM}}' \sim \frac{1}{g_{\text{YM}}^2} \text{tr} \int dx^- d^4x \sqrt{g} \left( \zeta^{1/2} C^{IJK} X^I [X^J, X^K] + C^{Iij} X^I F_{ij} \right.
\]
\[ + \zeta^{1/2} C^{Ji} X^I D_i X^J + \zeta^{-1/2} C^{ijk} \left( A_i \partial_j A_k - \frac{2i}{3} A_i A_j A_k \right) \]
\[ + i \bar{\psi}_- C_{\mu \nu \lambda} \Gamma^{\mu \nu \lambda} \psi_+ + i \zeta \bar{\psi}_+ C_{\mu \nu \lambda} \Gamma^{\mu \nu \lambda} \psi_- - \zeta C^{I\nu \lambda} C_{\nu \lambda} X^I X^J \right) , \tag{5.12} \]

Thus in the limit \( \zeta \rightarrow 0 \) the only terms in \( S' \) that survive are precisely those in (5.4). The only exception is the Chern-Simons-like term which diverges, and therefore is not consistent with taking the limit.

### 6 Conclusions and Comments

In this paper we have performed a general reduction of the M5-brane along a null Killing direction. We then extended the result to a non-abelian theory. The result is a class of
supersymmetric gauge theories in 4+1 dimensions but without Lorentz invariance. We also explored the effect of coupling of background supergravity fluxes to the M5-brane and twistings of the normal bundle.

The results presented above include and generalise earlier results. In particular simply setting \( u = v = \sigma = 0 \) and \( g_{ij} = \delta_{ij} \) recovers the flat space case [3], and setting \( u_i = \frac{1}{2} \Omega_{ij} x^j \) recovers the metric and action of of [4].

An interesting feature of this construction is how the information of \( H \) is encoded in a consistent way into the Lagrangian. Our isometry creates a natural split in the field; \( H_{ij} = F_{ij}, H_{i-} = F_i, \) and \( H_{ij} = G_{ij} \). \( H \) is self-dual and closed, which is problematic for a Lagrangian. But here we find \( F \) is closed but with no self-duality constraint off-shell, whereas \( G \) satisfies a self-duality constraint but is not closed. On-shell the self-duality of \( G \) enforces anti-self-duality condition on \( F \) as it’s equation of motion. In effect we have introduced a Lagrange multiplier, but without adding any new unphysical fields to our Lagrangian; \( H \) provides its own Lagrange multiplier. It would be interesting to explore how this construction ties in with the six-dimensional lagrangian approach of [25–27].

In case 2 \( G_{ij} \) imposes the constraint \( F = - \star F \) and therefore the dynamics is restricted to the space of anti-self-dual gauge fields on the four-dimensional submanifold. Such field configurations are then solved for by the ADHM construction in terms of moduli. The remaining part of the action leads to one-dimensional motion on the instanton moduli space [9, 24]. This is in keeping with the various DLCQ proposals such as [11, 12]. In case 1 \( G_{ij} \) imposes the constraint \( F = - \star F \) but here there are time-derivative terms and hence there is no simple reduction to motion on a moduli space.

The general form for the action includes an \( F \wedge F \wedge v \) term which we can think of as a mixed Chern-Simons term between diffeomorphisms and gauge transformations. In particular for case 1 this term vanishes but in in case 2 we have \( u = 0 \) and so \( F_{ij} = F_{ij} \). In this case if we let \( v(5) = v_i dx^i + \sigma dx^- \) then the metric admits a diffeomorphism \( v(5) \rightarrow v(5) + d(5) \omega \) where \( \omega \) depends on \( x^i \) and \( x^- \). We can rewrite the terms involving \( F \) as

\[
\mathcal{L}_F = \frac{1}{2} \text{tr}(F_+ \wedge \star F_+) - \frac{1}{8} \sigma \text{tr}((F - \star F) \wedge \star (F - \star F)) + \frac{1}{2} \text{tr}(F \wedge G) + \mathcal{L}_{cs},
\]

where

\[
\mathcal{L}_{cs} = -\frac{1}{4} \text{tr}(F_{(5)} \wedge F_{(5)}) \wedge v_{(5)},
\]

and \( F_{(5)} = F + F_+ \wedge dx^- \). Thus under a diffeomorphism \( v(5) \rightarrow v(5) + d(5) \omega \) the Lagrangian shifts by a total derivative. Alternatively we can write

\[
\mathcal{L}_{cs} = \frac{1}{4} \text{tr} \left( A_{(5)} \wedge dA_{(5)} - \frac{2i}{3} A_{(5)} \wedge A_{(5)} \wedge A_{(5)} \right) \wedge dv_{(5)},
\]

in which case the gauge symmetry is only preserved up to a boundary term. We cannot write this term in a way which makes explicit both of these invariances simultaneously. Thus we see that \( \mathcal{L}_{cs} \) mixes a five-dimensional diffeomorphism with the \( U(1) \) part of the gauge symmetry.
We hope that the results will be of use in studying the $(2,0)$ and related theories reduced on non-trivial manifolds through DLCQ-type constructions\cite{11,12}. For example one could consider theories of class $\mathcal{S}$\cite{19} obtained by reduction of M5-branes on a Riemann surface $\Sigma$. Our results here should allow for a systematic construction in terms of motion on the moduli space of instantons on $\mathbb{R}^2 \times \Sigma$, i.e. Hitchin systems, coupled to scalars, fermions and possible additional data associated with singularities of $\Sigma$.

Appendix A: Conventions

In this paper our conventions we use $\mu, \nu = 0, 1, 2, \ldots, 10$ and consider an M5-brane with worldvolume coordinates $x^M$, $M = 0, 1, 2, \ldots, 5$. However we also introduce light cone coordinates

$$x^+ = \frac{1}{\sqrt{2}}(x^0 + x^5), \quad x^- = \frac{1}{\sqrt{2}}(x^0 - x^5), \quad x^i, \ i = 1, 2, 3, 4.$$ \hspace{1cm} (6.4)

We will use hats to denote six-dimensional geometrical quantities.

Fermions are be dealt with by using Gamma matrices that satisfy a flat Clifford algebra in eleven dimensions (again with light cone Minkowski metric). All other Gamma matrices appearing in our work are derived from this basis as outlined below. Underlined indices refer to the tangent space.

| Notation | Definition | Description | Indices |
|----------|------------|-------------|---------|
| $\Gamma^\mu$ | $\{\Gamma^\mu, \Gamma^\nu\} = 2\eta^{\mu\nu}$ | Matrices of Spin(1,10) | $\mu \in \{0, \ldots, 10\}$ |
| $\Gamma^M$ | $\{\Gamma^M, \Gamma^N\} = 2\eta^{MN}$ | On the brane | $M \in \{+, -, 1, \ldots, 4\}$ |
| $\Gamma^I$ | $\{\Gamma^I, \Gamma^J\} = 2\delta^{IJ}$ | Off the brane | $I \in \{6, \ldots, 10\}$ |
| $\hat{\Gamma}^M$ | $\hat{\epsilon}^M\hat{\epsilon}^M \Gamma^M$ | 6d curved index Gamma matrices | $M \in \{+, -, 1, \ldots, 4\}$ |
| $\Gamma^i$ | $\epsilon^i \Gamma^i$ | 4d curved index Gamma matrices | $i \in \{1, \ldots, 4\}$ |
To avoid the confusion of whether or not $\Gamma^\pm$ means $\Gamma^\text{plus}$ or $\Gamma^\text{plus minus}$, we will only use
\[
\Gamma^+ = \frac{\Gamma^0 + \Gamma^5}{\sqrt{2}}, \quad \Gamma^- = \frac{\Gamma^0 - \Gamma^5}{\sqrt{2}},
\]
\[
\Gamma_+ = \frac{\Gamma_0 + \Gamma_5}{\sqrt{2}}, \quad \Gamma_- = \frac{\Gamma_0 - \Gamma_5}{\sqrt{2}}.
\]
(6.5)
The relations
\[\hat{\Gamma}^+ = \Gamma^+ - \sigma \Gamma^- - v_i \Gamma^i, \quad \hat{\Gamma}^- = \Gamma^- - u_i \Gamma^i \quad \hat{\Gamma}^i = \Gamma^i\]
\[
\hat{\Gamma}_+ = \Gamma_+, \quad \hat{\Gamma}_- = \sigma \Gamma_+ + \Gamma_-, \quad \hat{\Gamma}_i = (v_i + \sigma u_i) \Gamma^+ + u_i \Gamma^- + \Gamma^i,
\]
will be repeatedly used.

The subscript ± on spinors labels their eigenvalue under $\Gamma_{05}$, e.g.:
\[\Gamma_{05} \epsilon_\pm = \pm \epsilon_\pm.
\]
(6.7)
In addition we always have that $\Gamma_{012345} \epsilon = \epsilon$ and $\Gamma_{012345} \psi = -\psi$. This has the crucial consequence of giving certain spinor bilinears definite duality under the 4d Hodge star. Consider the following spinor bilinear
\[\bar{\epsilon} \Gamma_{ij} \psi.
\]
(6.8)
Since $\Gamma_{012345} \psi = -\psi$, it follows that
\[\Gamma_{12} \psi = \Gamma_{34} \Gamma_{05} \psi,
\]
(6.9)
or in general
\[\Gamma_{ij} \psi = \frac{1}{2} \epsilon_{ijkl} \Gamma^{kl} \Gamma_{05} \psi.
\]
(6.10)
From this its easy to see that $\Gamma_{ij} \psi^+$ is self-dual, while $\Gamma_{ij} \psi^-$ is anti-self-dual under the four-dimensional Hodge star. Since $\epsilon$ has the opposite chirality under $\Gamma_{012345}$, these are reversed: $\Gamma_{ij} \epsilon^+$ is anti-self-dual, $\Gamma_{ij} \epsilon^-$ is self-dual.

**Appendix B: The Background**

The vielbein (and inverse) for the metric are given by $\hat{e}^M_N \hat{\eta}_MN = \hat{g}_{MN}$, with $\hat{\eta}_MN$ the light-cone Minkowski metric in six dimensions. This results in
\[
\hat{e}^M_M = \begin{pmatrix}
1 & \sigma & v_i + \sigma u_i \\
0 & 1 & u_i \\
0 & 0 & e^i_i
\end{pmatrix}, \quad \hat{e}^M_M = \begin{pmatrix}
1 & -\sigma & -v_i \\
0 & 1 & -u_i \\
0 & 0 & e_i^i
\end{pmatrix},
\]
(6.11)
with $e^i_j$ being the vielbein for the four-dimensional metric $g_{ij}$. Where $u^i$ and $v^i$ are defined to have their index raised by $g_{ij}$, such that dot products are defined also with $g_{ij}$. We also note that
\[
\hat{g} = \det(\hat{g}_{MN}) = \det(e^M_N)^2 \det(\hat{\eta}_{MN}) = -\det(g_{ij}) .
\] (6.12)

Adding the fermions requires knowledge of the spin connection terms, the non zero terms of which are
\[
\begin{align*}
\hat{\omega}_{+i} &= \frac{1}{2} \partial_+ u_i \\
\hat{\omega}_{+ij} &= \partial_+ [u_j] \\
\hat{\omega}_{-i} &= \frac{1}{2} \partial_- u_i \\
\hat{\omega}_{-i} &= -\partial_- \sigma + u_i \partial_- \sigma + 2 \sigma \partial_- u_i + \partial_- v_i \\
\hat{\omega}_{-ij} &= \partial_- [v_j + 2 \sigma u_j] + u_i [\partial_- v_j] - v_i [\partial_- u_j] - \epsilon^i [\partial_- e_{ij}] \\
\hat{\omega}_{i+} &= -\frac{1}{2} \partial_- u_i \\
\hat{\omega}_{i+j} &= \partial_+ [u_i] \\
\hat{\omega}_{-j} &= \partial_- [v_j + 2 \sigma u_j] + 2 u_i \partial_- \sigma + \partial_- (u_i (v_j + \sigma u_j)) - \frac{1}{2} \partial_- g_{ij} \\
\hat{\omega}_{ijk} &= \omega_{ijk} + \partial_j (u_i (v_k + \sigma u_k)) - \partial_k (u_i (v_j + \sigma u_j)) + \partial_i (u_j v_k) + 2 (v_j + \sigma u_j) \partial_i u_i \\
\end{align*}
\] (6.13)

where $\omega_{ijk}$ is the four-dimensional spin connection for $D_i$, the Levi-Civita connection for $g_{ij}$ on our euclidean submanifold.
