Abstract

76 days after the COVID-19 epidemic was contained in Wuhan, the Chinese government carried out a citywide SARS-CoV-2 nucleic acid testing for all the residents from May 14th to June 1st, 2020. Our hospital tested 107,662 residents around Huanan Seafood Market, uncovering a positivity rate of 0.006%.

Keywords: asymptomatic; infectious; COVID-19; Huanan Seafood Market
After three-month nationwide efforts and lockdown of the city of Wuhan for 76 days from January 23rd to April 8th, 2020, the SARS-CoV-2 epidemic in Wuhan was contained. On April 26th, 2020, the number of both hospitalized COVID-19 patients and daily new cases in Wuhan decreased to zero. However, sporadic cases have been reported since May 11th, 2020, more than a month after the lockdown were lifted. One possibility was that patients who were discharged might have positive results for SARS-CoV-2 nucleic acid again[1]. Chinese government decided to carry out a citywide mass nucleic acid testing of SARS-CoV-2 for all of the citizens in Wuhan city. The purpose is not only to understand possible asymptomatic transmission, but also to prepare for resumption of normal life including work and school.

Here we report the results of the mass nucleic acid testing of 107,662 residents living in Jianghan District, where the Huanan Seafood Market was located. The Huanan Seafood Market was the possible point of origin of the COVID-19 pandemic and has been closed since the outbreak of COVID-19. Jianghan District, located in the central area of Wuhan city, has a total population of 683,492. On February 22nd, 2020, there were 7,099 confirmed COVID-19 patients in this District, one of the hardest-hit areas at that time. From May 13th, 2020 to May 26th, 2020, all of the 683,492 residents were tested for SARS-CoV-2 nucleic acid by reverse transcription-polymerase chain reaction (RT-PCR). Among them, 107,662 residents were tested at our hospital, Wuhan Red Cross Hospital. The test was all-inclusive testing for all residents regardless of gender and age. Among them, 51% were male. The median age was 42 years (range, 4-102 years). 10% were under 20 years old and 15% aged from 20 to 29. People who range from age 50-59 accounted for 17%. 23,696 (22%) of them were over 60 years old, including three over 100 years old.

Among the 107,662 residents we tested, six were tested positive for SARS-CoV-2, accounting for 0.006% (equivalent to 60 cases per million). These six patients lived at least
1.5 kilometers away from the Huanan Seafood Market and none of them clustered together (Figure 1). Of the six patients, 5 (83.3%) were male and 4 (66.6%) were over 50 years old. The youngest one was an eighteen-year-old man. They were asymptomatic, with no respiratory symptoms or abnormal CT chest findings. Three of them were diagnosed with COVID-19 in March and were discharged after negative testing and resolution of symptoms in April 2020. These three recovered patients had recurrence of positive SARS-CoV-2 nucleic acid testing without any symptoms (Table 1).

Combining serology antibody testing with RT-PCR results may enhance COVID-19 detection sensitivity and accuracy during the mass testing. As reported, IgM peaks between days 5 and 12, then IgM drops slowly and IgGs reach peak concentrations after day 20[2]. Of the six SARS-CoV-2 nucleic acid positive patients, five had antibody IgM and IgG tests: two were positive for both IgM and IgG antibodies, two were IgG positive only, and one was IgM positive only; the sixth one did not have antibody tests done. The close contacts of the six patients did not have any positive results by either RT-PCR or antibody tests, which was same as other sporadic cases the entire Wuhan city.

At present, the proportion of asymptomatic patients in the whole population of Wuhan city is quite low. As reported on June 2nd, 2020, 9,899,828 people underwent mass SARS-CoV-2 nucleic acid testing in Wuhan from May 14th to June 1st, 300 asymptomatic patients were identified, with a detection rate of 0.003%. 1,174 close contacts were traced and their RT-PCR results were all negative[3]. Both asymptomatic patients and close contacts have been quarantined for medical observation. An important finding is that the positive rate of our study near Huanan Seafood Market was 0.006%, double the rate of 0.003% in the entire Wuhan city. As Huanan seafood market was the possible point of origin of the COVID-19 outbreak in China, it’s understandable that the number of patients in the surrounding area (Jianghan District) was higher than other areas. Overall, 0.006% was still a very low
positivity rate. Therefore, Jianghan District, like the rest of Wuhan city, was not considered a high-risk area.

Such an unprecedented mass testing of nearly 10 million people provides important information for global prevention of SARS-CoV-2. One major goal of testing would be to identify infected people with no symptoms, to understand if they still spread the virus[4]. It’s reassuring that the 1,174 close contacts were all tested negative. Besides, it has been reported that the SARS-CoV-2 viral culture tests of the 300 asymptomatic patients were all negative, implying no infectivity[5]. As recent reports of new cases of Xinfadi Market in Beijing and new imported cases remind continuous caution, everyone needs to be aware of the importance of self-protection. Perhaps the occurrence of sporadically confirmed cases in general populations will be a feature for a long period of time to come. To prevent the “second wave” of COVID-19, wearing face mask and other personal hygiene practice should become a routine in the coming days.
**Author Contributions:** JwL, CW, XZ, LC, XW, XG and NX collected the epidemiological and clinical data and processed statistical data. JwL, CW, XZ and LC drafted the manuscript and share first authorship. NX, JhL and ZL revised the final manuscript. NX is responsible for summarizing all epidemiological and clinical data.

**Conflict of interest:** No author has a potential conflict of interest.

**Funding:** This work was supported by grants 2016YFC1306600 and 2018YFC1314700 from the National Key R&D Program of China, grants 81873782 from the National Natural Science Foundation of China (all to NX). The funding sources plays no role in the study design, data collection and manuscript writing.
