Theoretical Division, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

Based on a microscopic model, we study the interplay between superconductivity and antiferromagnetism in a multi-layered system, where two superconductors are separated by an antiferromagnetic region. Within a self-consistent mean-field theory, this system is solved numerically. We find that the antiferromagnetism in the middle layers profoundly affects the supercurrent flowing across the junction, while the phase difference across the junction influences the development of antiferromagnetism in the middle layers. This study may not only shed new light on material design and material engineering, but also bring important insights to building Josephson-junction-based quantum devices, such as SQUID and superconducting qubit.

I. INTRODUCTION

As a remarkable aspect of high-$T_c$ superconductivity, its unique characteristics may result from the competition between more than one type of order parameter. Historically, the typical antagonistic relationship between superconductivity and magnetism has led researchers to avoid using magnetic elements, such as iron, as potential superconducting (SC) material. However, it is now well accepted that the unconventional superconductivity emerging upon doping is closely related to the antiferromagnetism (AFM) in parent compounds. Recent research theme in high-$T_c$ cuprates centers on how to establish the connection between antiferromagnetic (AF) and $d$-wave SC (DSC) orderings, i.e., whether they compete with each other or coexist microscopically. This issue is a subject of current discussions. Depending on material details, some compounds show the coexistence of DSC and AFM while others exhibit microscopic separation of these two phases. Engineered heterogeneous systems and multi-layered high-$T_c$ cuprates offer a unique setting to study the interplay between DSC and AFM. In these systems, the disorder effect can be minimized significantly with atomically smooth interfaces. Experimentally, no mixing of DSC and AFM was reported in the heterostructure artificially grown by stacking integer number of La$_{1.85}$Sr$_{0.15}$CuO$_4$ and La$_2$CuO$_4$ layers. Meanwhile microscopic evidence for the uniform mixed phase of AFM and DSC in outer CuO$_2$ planes was reported on a Hg-based five-layered cuprate. Theoretically, Demler et al. have studied the proximity effect and Josephson coupling in the SO(5) theory of high-$T_c$ superconductors. Depending on the thickness, the middle antiferromagnetic region could behave like a superconductor, metal or insulator. On the other hand, it was shown in the perturbation theory that the spin exchange coupling in the insulating AF layer can allow the tunneling of Cooper pairs.

In this article, we study microscopically a multi-layered system with two superconductors separated by AF layers. Through self-consistent mean-field theory and numerical diagonalization, we are able to solve the Hamiltonian, which allows us to study the interplay between DSC and AFM in detail. Varying some external parameters, such as the SC phase difference across the system $\varphi_c$ and Coulomb interaction $U$ in the AF layers leads to interesting results about the interplay.

II. MODEL AND SETUP

The model system under consideration is schematically presented in Fig. 1 for which the Hamiltonian can be written as:

$$H = - \sum_{i,j,\sigma} t_{i,j} c^\dagger_{i,\sigma} c_{j,\sigma} + \sum_i U_i (n_{i,\uparrow} - \frac{1}{2}) (n_{i,\downarrow} - \frac{1}{2}) - \frac{1}{2} \sum_{i,j} V_{ij} n_i n_j - \mu \sum_i n_i,$$  

(1)

where $t_{i,j}$ denotes the hopping integral between the nearest neighbor sites. For in-plane ($X$-$Y$ plane) hopping, $t_{i,j} = t$, and for inter-layer ($Z$ direction) hopping, $t_{i,j} = t_{\perp}$. $c_{i,\sigma} (c^\dagger_{i,\sigma})$ is the annihilation (creation) operator of electrons on the $i$th lattice site with spin $\sigma$ ($\sigma = \uparrow, \downarrow$).
The quantity $n_{i,a} = c_{i,a}^\dagger c_{i,a}$ is the number operator on the $i$th lattice site. Both $U_i$ and $V_{ij}$ are positive. $U_i$ indicates the on-site repulsive Coulomb interaction, which is nonzero only in the middle layers, and $V_{ij}$ describes the in-plane nearest neighbor attractive interaction, which is nonzero only in the SC layers. We are going to fix the phase of the SC order parameter in the first (far left) and the last (far right) layer at $\varphi_L$ and $\varphi_R$, respectively, which can be introduced by a gauge flux.

When there is no inter-layer coupling, $t_\perp = 0$, the system is decomposed into individual two-dimensional (2D) systems. It is known that in a 2D SC layer, the system is decomposed into individual two-dimensional (2D) systems. It is known that in a 2D SC layer, the on-site repulsive interaction $U$ describes the nearest neighbor inter-plane hopping, $\xi_{Q,n}$, $n$, $m$, and $t$, $\perp$ $(\alpha)$ is equal to $\delta_{n,m+1} + \delta_{n,m-1}$ describes the nearest neighbor inter-plane hopping, $\xi_{Q,n}$ is equal to $\delta_{n,m}$. The on-site repulsive interaction $U$ leads to a nonzero energy gap $\Delta$ with $d$-wave symmetry, and in a 2D AF layer the on-site repulsive interaction $U_i$ leads to a nonzero $(\pi, \pi)$ spin density wave (SDW) order.

\[
\sum_m \begin{bmatrix}
\xi_{kn} \delta_{nm} + t_{nm} & -\frac{U}{2} M_n \delta_{nm} & \Delta_{kn} \delta_{nm} \\
-\frac{U}{2} M_n \delta_{nm} & \xi_{k+Q,n} \delta_{nm} + t_{nm} & \Delta_{kn} \delta_{nm} \\
0 & -\frac{U}{2} M_n \delta_{nm} & \xi_{k+Q,n} \delta_{nm} - t_{nm} \\
\end{bmatrix} \begin{bmatrix}
0 \\
\frac{\Delta_{k+Q,n} \delta_{nm}}{\Delta_{kn} \delta_{nm}} \\
-\frac{\Delta_{k+Q,n} \delta_{nm}}{\Delta_{kn} \delta_{nm}} \\
\end{bmatrix}
= E_{\alpha} \begin{bmatrix}
u_{k,m,u}^\alpha \\
\nu_{k+Q,n,\uparrow}^\alpha \\
\nu_{k+Q,n,\downarrow}^\alpha \\
\end{bmatrix},
\]

where $m$ and $n$ label the layer number; $\vec{k}$ and $\vec{k} + \vec{Q}$ with $\vec{Q} = (\pi, \pi)$ denote the wave vectors in the first Brillouin zone of the X-Y plane, $t_{nm} = t_\perp (\delta_{n,m+1} + \delta_{n,m-1})$ describes the nearest neighbor inter-plane hopping, $\xi_{kn} = -2t(\cos k_x + \cos k_y) - \mu$ is the normal metal dispersion relation, $\mu$ is the chemical potential, the variables $U_n$ is equal to $U$ in the AF layers and zero otherwise while $V_n$ is equal to $V$ in the SC layers and zero otherwise. The superconducting pairing potential $\Delta_{kn} = V_n \Psi_n(\cos k_x - \cos k_y)/2$, where $\Psi_n$ is the superconducting pairing wavefunction. Obviously, the superconducting pairing potential, which is the SC order parameter has the same phase as that of the superconducting pairing wavefunction. $M_n = \langle n_n, \uparrow \rangle - \langle n_{n-1}, \downarrow \rangle$ describes the SDW in the $n$-th layer. The average electron number $\langle n_{n,\uparrow} \rangle$, $\langle n_{n,\downarrow} \rangle$ and the SC pairing wavefunction $\Psi_n$ can be determined self-consistently through iteration over the following relation:

\[
\Psi_n = \frac{2}{N} \sum_{k,\alpha} \frac{(\cos k_x - \cos k_y)}{2} g(u, v) \tanh \frac{\beta E_{\alpha}}{2},
\]

\[
\langle n_{n,\uparrow} \rangle = \frac{1}{N} \sum_{k,\alpha} \left| \nu_{k,n,\uparrow}^\alpha + \nu_{k+Q,n,\uparrow}^\alpha \right|^2 f(E_{\alpha}),
\]

\[
\langle n_{n,\downarrow} \rangle = \frac{1}{N} \sum_{k,\alpha} \left| \nu_{k,n,\downarrow}^\alpha + \nu_{k+Q,n,\downarrow}^\alpha \right|^2 f(-E_{\alpha}),
\]

where $N = N_x \times N_y$ is the sites number in a 2D plane. $\vec{k}$ samples half of the first Brillouin zone. $g(u, v) = u_{k,n,\uparrow}^\alpha v_{k+Q,n,\uparrow}^\alpha + u_{k+Q,n,\uparrow}^\alpha v_{k,n,\uparrow}^\alpha$, and $f(E) = 1/(1+e^{\beta E})$ is the Fermi distribution. Through this simplification, the multi-layered system is then solved numerically. We are especially interested in the interplay between the DSC and the AFM, which is characterized by the SDW $M_n$ and the SC pairing wavefunction $\Psi_n$. We will focus on zero temperature $T = 0$. The size of X-Y plane is $N_x = N_y = 40$. The total layer number is $N_z = 22$. The two middle layers are AF layers ($U_n = U, V_n = 0$, for $n = 11, 12$), and the rest are SC layers ($U_n = 0, V_n = V$, for $n = 1, 2, \ldots, 10$, and $n = 13, \ldots, 22$). For simplicity, we choose $t = 1, t_\perp = 0.1, V = 1.5$, and $\mu = 0$. We will vary the control parameters, such as $U$ and $\delta \varphi = \varphi_L - \varphi_R$, to study the competition between DSC and AFM. When the phase difference $\delta \varphi$ is introduced, there is a current flowing across the system and its expression is given by:

\[
I = \frac{2t_\parallel e}{N} \sum_{k,\alpha} \text{Im} \left[ \left| \nu_{k,n,\uparrow}^\alpha \nu_{k+Q,n,\uparrow}^\alpha + \nu_{k+Q,n,\uparrow}^\alpha \nu_{k,n,\uparrow}^\alpha \right| f_+ \right. \\
\left. + \left| \nu_{k,n,\downarrow}^\alpha \nu_{k+Q,n,\downarrow}^\alpha + \nu_{k+Q,n,\downarrow}^\alpha \nu_{k,n,\downarrow}^\alpha \right| f_- \right],
\]

where $f_\pm = f(\pm E_\alpha)$.

### III. INFLUENCE OF ANTI-FERROMAGNETISM ON SUPERCONDUCTIVITY

In the model introduced above, the change of the Coulomb interaction $U$ in the middle layers
can drive a metal-Mott insulator phase transition at a certain value $U_c$. Correspondingly, the multilayered system changes from a superconductor/normal metal/superconductor (SNS) weak link\textsuperscript{16} to a superconductor/insulator/superconductor (SIS) Josephson junction\textsuperscript{12}. The studies of SNS and SIS junctions with static potential barrier have been well documented\textsuperscript{16–18}. Here we start from a microscopic model and drive the middle layers to change from one electronic state into another by tuning the on-site Coulomb interaction $U$. We are interested in how the SC pairing wavefunction and the current across the junction change with the Coulomb interaction $U$. We plot the current as a function of the phase difference $\delta \phi$ in Fig. 2. It can be seen that below a threshold value of $U_c \approx 0.8$, the current is a piecewise periodic function. In each periodic region, it varies linearly with $\delta \phi$. This agrees with the result obtained in Ref.\textsuperscript{16} for a junction with a normal metal. We also find that when the Coulomb interaction is larger than $U_c$, the current as a function of $\delta \phi$ changes gradually with the increase of $U$. When $U$ is in the range $0.8 < U < 1.5$, the current shows a shape intermediate between a piecewise linear function and a sinusoidal function. Similar results have been observed in Refs.\textsuperscript{2,13,16} when one varies the temperature or the thickness of the middle layers instead of the the Coulomb interaction $U$. When $U \approx 2.0$, the current is well approximated by a sinusoidal function of $\delta \phi$ (see Fig. 2), which is a typical feature of the dc Josephson junction (JJ) current\textsuperscript{17}. The magnitude of current decreases rapidly with the increase of $U$.

In order to have a better understanding of the influence of AFM on DSC, we plot the absolute value and the phase of the current across the junction as a function of the phase difference $\delta \phi$ of two superconductors for different $U$. Here $V = 1.5$, $t_{\perp} = 0.1$, $N_x = N_y = 40$, $N_z = 22$. Up panel: $U = 0$, 0.1, 0.2, 1.5, and $\delta \phi = 0 \sim \pi$. Down panel: $U = 2.0$ and $\delta \phi = 0 \sim 2\pi$.

![Figure 2: Current across the junction as a function of the phase difference $\delta \phi$.](image)

**FIG. 2:** Current across the junction as a function of the phase difference $\delta \phi$ of two superconductors for different $U$. Here $V = 1.5$, $t_{\perp} = 0.1$, $N_x = N_y = 40$, $N_z = 22$. Up panel: $U = 0$, 0.1, 0.2, 1.5, and $\delta \phi = 0 \sim \pi$. Down panel: $U = 2.0$ and $\delta \phi = 0 \sim 2\pi$.

When one continues to increase $U$, the middle layers becomes more opaque and the superconducting pairing wavefunction is completely suppressed in this region. As a result, the tunneling of Cooper pairs will be completely quenched, and the two comprising superconductors become decoupled.

We also would like to mention that when the middle layers are in the normal metallic state, the current across the junction is a mesoscopic effect\textsuperscript{20}. The current is proportional to the phase gradient of the SC pairing wavefunction. That is, when one increases the number of SC layers, the current will decrease and finally vanish. However, when the middle layer is in the AF state, the whole system becomes a JJ. The current of a JJ is no longer a mesoscopic effect. It is completely determined by the phase difference of the SC pairing wavefunction on both ends of the system. Therefore, it will not decrease with the increase of the number of the SC layers. In this sense we say that AFM insulator layers enhance supercurrent.

**IV. INFLUENCE OF SUPERCONDUCTIVITY ON ANTIFERROMAGNETISM**

In the above discussion, we find the profound influence of the Coulomb interaction $U$ (and hence AFM) of the middle layers on the DSC. We now study the back-action of DSC on AFM. We will fix the phase difference $\delta \phi$ at different values, and see if the SDW in the middle layers
changes with $\delta \phi$. We plot in Fig. 3 the SDW as a function of $U$ for various values of $\delta \phi$. Clearly, the SDW in the middle layers is influenced by $\delta \phi$ in certain range of $U$. When $\delta \phi = \pi$, the critical value $U_c$, after which the SDW develops, is much smaller than in the case of $\delta \phi = 0$, though the current is zero in both cases. This is very similar to the result in Ref. 13 that the middle AF layers have profound influence on the DSC. A metal-Mott insulator phase transition makes the multi-layered system. It is revealed that the SDW critical point $U_c$ will in-crease by $\delta \phi = \pi$ rather than a criticality as obtained for $\delta \phi = 0$. For $\delta \phi \in (0, \pi)$, the SDW critical point $U_c$ is less than that for $\delta \phi = 0$. This result is in agreement with that in Ref. 13.

In order to have a better understanding of the influence of the DSC on the AFM in the middle layers, we plot in Fig. 3 the local density of state (LDOS), as given by

$$\rho_{n,\uparrow}(E) = \frac{1}{N} \sum_{k,\alpha} |u_{k,n,\uparrow}(E) + v_{k+\mathbf{Q},n,\downarrow}(E)|^2 \left[ \frac{\partial f(\omega)}{\partial \omega} \right] (5a)$$

$$\rho_{n,\downarrow}(E) = \frac{1}{N} \sum_{k,\alpha} |v_{k,n,\downarrow}(E) + v_{k+\mathbf{Q},n,\uparrow}(E)|^2 \left[ \frac{\partial f(\omega')}{\partial \omega'} \right] (5b)$$

where $\omega = E - E_n$ and $\omega' = E + E_n$. From Fig. 3 we can see a sharp intensity decay of LDOS at $E_F$ when $\delta \phi = 0$. When $\delta \phi = \pi$, the LDOS exhibits a peak structure at $E_F$. Since the development of the SDW is also determined by the normal-state DOS at low energies, it explains the different SDW critical behavior between the cases with $\delta \phi = \pi$ and $\delta \phi = 0$.

V. CONCLUSION AND DISCUSSION

We have studied the interplay between the DSC and AFM in a multi-layered system. It is revealed that the AF layers have profound influence on the DSC. A metal-Mott insulator phase transition makes the multi-layer system change from a SNS to a SIS junction. We have also established the connection between the profile of the SC phase distribution and the current-phase dependence.
We find that when the barrier of the middle layers is not high enough (metal or semiconductor regime), the middle layers cannot maintain a step-function-like phase of two superconductors on two sides. Accordingly, the current across the junction will deviate from a sinusoidal function of the phase difference. When the barrier of the middle layer is high (deep insulator regime), as predicted by Josephson\textsuperscript{17}, the phase across the junction is a step function, and the current is a sinusoidal function of the phase difference. Meanwhile, the phase difference across the system will dramatically influence the development of SDW in the middle layers. The results from our simulations may shed new light on material engineering. The DSC and AFM can coexist in a single layer, but they also compete with each other. Another important insight from the present study is the microscopic model of JJ. JJ has been widely used in a lot of quantum devices, such as in SQUID for ultra-sensitive magnetic field measurement and superconducting qubit\textsuperscript{22} for quantum computing. Our study provides a microscopic theory for JJ, hence has possible applications in building adaptive JJ based devices by engineering the middle layers of the JJ. Finally, with the development of experimental techniques, it is now possible to synthesize heterogeneous systems with layer by layer at atomic scale\textsuperscript{22}. We expect that our results can be experimentally verified, as some experiments on engineered material have been reported\textsuperscript{11,12,22}.
