CLONES CONTAINING ALL ALMOST UNARY FUNCTIONS

MICHAEL PINSKER

Abstract. Let $X$ be an infinite set of regular cardinality. We determine all clones on $X$ which contain all almost unary functions. It turns out that independently of the size of $X$, these clones form a countably infinite descending chain. Moreover, all such clones are finitely generated over the unary functions. In particular, we obtain an explicit description of the only maximal clone in this part of the clone lattice. This is especially interesting if $X$ is countably infinite, in which case it is known that such a description cannot be obtained for the second maximal clone over the unary functions.

1. Introduction

1.1. Clones and almost unary functions. Let $X$ be a set and denote by $\mathcal{O}(n)$ the set of all $n$-ary functions on $X$. Then $\mathcal{O} = \bigcup_{n=1}^{\infty} \mathcal{O}(n)$ is the set of all functions on $X$. A clone $\mathcal{C}$ over $X$ is a subset of $\mathcal{O}$ which contains the projections and which is closed under compositions. The set of all clones over $X$ forms a complete lattice $\text{Clone}(X)$ with respect to inclusion. This lattice is a subset of the power set of $\mathcal{O}$. The clone lattice is countably infinite if $X$ has only two elements, but is of size $2^{2^{\aleph_0}}$ for cardinality of $X$ finite and greater than two. For infinite $X$ we have $|\text{Clone}(X)| = 2^{|X|}$.

Let $X$ be of infinite regular cardinality from now on unless otherwise stated. We call a subset $S \subseteq X$ large iff $|S| = |X|$, and small otherwise. If $X$ is itself a regular cardinal, then the small subsets are exactly the bounded subsets of $X$. A function $f(x_1, ..., x_n) \in \mathcal{O}(n)$ is almost unary iff there exists a function $F : X \to \mathcal{P}(X)$ and $1 \leq k \leq n$ such that $F(x)$ is small for all $x \in X$ and such that for all $(x_1, ..., x_n) \in X^n$ we have $f(x_1, ..., x_n) \in F(x_k)$. If we assume $X$ to be a regular cardinal itself, this is equivalent to the existence of

Key words and phrases. clone lattice, maximal clones, polymorphisms, median functions, almost unary functions, regular cardinals.

The author is supported by DOC [Doctoral Scholarship Programme of the Austrian Academy of Sciences]. He is grateful to M. Goldstern for drawing his attention to the subject and for his remarks on the paper, to L. Heindorf for his comments and to the II. Mathematisches Institut at Freie Universität Berlin for their hospitality during his visit.
a function $F \in \mathcal{O}^{(1)}$ and a $1 \leq k \leq n$ such that $f(x_1, ..., x_n) < F(x_k)$ for all $(x_1, ..., x_n) \in X^n$. Because this is much more convenient and does not influence the properties of the clone lattice, we shall assume $X$ to be a regular cardinal throughout this paper. Let $\mathcal{U}$ be the set of all almost unary functions. It is readily verified that $\mathcal{U}$ is a clone (see e.g. [1]). We will determine all clones which contain $\mathcal{U}$; in particular, such clones contain $\mathcal{O}^{(1)}$.

1.2. Maximal clones above $\mathcal{O}^{(1)}$. A clone is called maximal iff it is a dual atom in $\text{Clone}(X)$. For finite $X$, the number of maximal clones is finite and all of them are known (a result due to I. Rosenberg [9], see also [8]). Moreover, the lattice is dually atomic in that case, i.e. every clone is contained in a maximal one. If $X$ is infinite, the situation is rather hopeless as another theorem by I. Rosenberg [10] states that there exist $2^{2^{|X|}}$ maximal clones, see also [5]. In addition, a recent result due to M. Goldstern and S. Shelah [4] shows that if the continuum hypothesis holds, then the clone lattice of a countable base set is not even dually atomic.

However, by Zorn’s lemma, the sublattice of $\text{Clone}(X)$ of functions containing $\mathcal{O}^{(1)}$ is dually atomic since $\mathcal{O}$ is finitely generated over $\mathcal{O}^{(1)}$. G. Gavrilov proved in [2] that for countably infinite $X$ there are only two maximal clones containing all unary functions. M. Goldstern and S. Shelah extended this result to clones on weakly compact cardinals in the article [5], but proved also that on other regular cardinals $X$ satisfying a certain partition relation there are even $2^{2^{|X|}}$ such clones.

There exists exactly one maximal clone above $\mathcal{U}$. So far, this clone has been defined using the following concept: Let $\rho \subseteq X^J$ be a relation on $X$ indexed by $J$ and let $f \in \mathcal{O}^{(n)}$. We say that $f$ preserves $\rho$ iff for all $r^1 = (r^1_i : i \in J), \cdots , r^n = (r^n_i : i \in J)$ in $\rho$ we have $(f(r^1_1, ..., r^n_1) : i \in J) \in \rho$. For a set of relations $\mathcal{R}$ on $X$ we define the set of polymorphisms $\text{Pol}(\mathcal{R})$ of $\mathcal{R}$ to be the set of all functions in $\mathcal{O}$ preserving all $\rho \in \mathcal{R}$. In particular, if $\rho \subseteq X^k$ is a set of $k$-ary functions, then a function $f \in \mathcal{O}^{(n)}$ preserves $\rho$ iff for all functions $g_1, ..., g_n$ in $\rho$ the composite $f(g_1, ..., g_n)$ is a function in $\rho$.

Write

$$T_1 = \mathcal{U}^{(2)} = \{ f \in \mathcal{O}^{(2)} : f \text{ almost unary} \}.$$ 

The following was observed by G. Gavrilov [2] for countable base sets and extended to all regular $X$ by R. Davies and I. Rosenberg [1]. Uniqueness on uncountable regular cardinals is due to M. Goldstern and S. Shelah [5].

Fact 1. Let $X$ have infinite regular cardinality. Then $\text{Pol}(T_1)$ is a maximal clone containing all unary functions. Furthermore, $\text{Pol}(T_1)$ is the only maximal clone containing all almost unary functions.
For $S$ a subset of $X$ we set
\[ \Delta_S = \{(x, y) \in S^2 : y < x\}, \quad \nabla_S = \{(x, y) \in S^2 : x < y\}. \]
We will also write $\Delta$ and $\nabla$ instead of $\Delta_X$ and $\nabla_X$. Now define
\[ T_2 = \{ f \in \mathcal{O}(2) : \forall S \subseteq X (S \text{ large } \rightarrow \text{ neither } f |_{\Delta_S} \text{ nor } f |_{\nabla_S} \text{ are 1-1}) \}. \]
The next result is due to G. Gavrilov [2] for $X$ a countable set and due to M. Goldstern and S. Shelah [5] for $X$ weakly compact.

**Fact 2.** Let $X$ be countably infinite or weakly compact. Then $\text{Pol}(T_2)$ is a maximal clone which contains $\mathcal{O}(1)$. Moreover, $\text{Pol}(T_1), \text{Pol}(T_2)$ are the only maximal clones above $\mathcal{O}(1)$.

The definition of $\text{Pol}(T_2)$ not only looks more complicated than the one of $\text{Pol}(T_1)$. First of all, a result of R. Davies and I. Rosenberg in [1] shows that assuming the continuum hypothesis, $T_2$ is not closed under composition on $X = \mathbb{N}_1$ and so it is unclear what $\text{Pol}(T_2)$ is. Secondly, on countable $X$, if we equip $\mathcal{O}$ with a certain natural topology which we shall specify later, then $T_2$ is a complete $\Pi_1^1$ set in that space and so is $\text{Pol}(T_2)$; in particular, neither $T_2$ nor $\text{Pol}(T_2)$ are countably generated over $\mathcal{O}(1)$ (see [3]). The set $T_1$ on the other hand is generated by a single binary function over $\mathcal{O}(1)$: Let $p$ be any injection from $X^2$ to $X$. For technical reasons we assume that 0 is not in the range of $p$. The next fact is folklore.

**Fact 3.** $\langle \{p\} \cup \mathcal{O}(1) \rangle = \mathcal{O}$.

For a subset $S$ of $X^2$ we write
\[ p_S(x_1, x_2) = \begin{cases} p(x_1, x_2) & , (x_1, x_2) \in S \\ 0 & , \text{otherwise} \end{cases} \]
M. Goldstern observed the following [3]. Since the result has not yet been published, but is important for our investigations, we include a proof here.

**Fact 4.** $\langle \{p_\Delta\} \cup \mathcal{O}(1) \rangle = \langle T_1 \rangle$.

**Proof.** Set $\mathcal{C} = \langle \{p_\Delta\} \cup \mathcal{O}(1) \rangle$. Since $p_\Delta(x_1, x_2)$ is obviously bounded by the unary function $\gamma(x_1) = \sup\{p_\Delta(x_1, x_2) : x_2 \in X\} + 1 = \sup\{p(x_1, x_2) : x_2 < x_1\} + 1$, where by $\alpha + 1$ we mean the successor of an ordinal $\alpha$, we have $p_\Delta \in T_1$ and hence $\mathcal{C} \subseteq \langle T_1 \rangle$.

To see the other inclusion, note first that the function
\[ q(x_1, x_2) = \begin{cases} p_\Delta(x_1, x_2) & , (x_1, x_2) \in \Delta \\ x_1 & , \text{otherwise} \end{cases} \]
is in $\mathcal{C}$. Indeed, choose $\epsilon \in \mathcal{O}^{(1)}$ strictly increasing such that $p_\Delta(x_1, x_2) < \epsilon(x_1)$ for all $x_1, x_2 \in X$ and consider $t(x_1, x_2) = p_\Delta(\epsilon(x_1), p_\Delta(x_1, x_2))$. On $\Delta$, $t$ is still one-one, and outside $\Delta$, the term is a one-one function of the first component $x_1$. Moreover, the ranges $t[\Delta]$ and $t[X^2 \setminus \Delta]$ are disjoint. Hence, we can write $q = u \circ t$ for some unary $u$. By the same argument we see that for arbitrary unary functions $a, b \in \mathcal{O}^{(1)}$ the function

$$q_{a, b}(x_1, x_2) = \begin{cases} a(p_\Delta(x_1, x_2)) & , (x_1, x_2) \in \Delta \\ b(x_1) & , \text{otherwise} \end{cases}$$

is an element of $\mathcal{C}$.

Now let $f \in T_1$ be given and say $f(x_1, x_2) < \delta(x_1)$ for all $x_1, x_2 \in X$, where $\delta \in \mathcal{O}^{(1)}$ is strictly increasing. Choose $a \in \mathcal{O}^{(1)}$ such that $a(p_\Delta(x_1, x_2)) = f(x_1, x_2) + 1$ for all $(x_1, x_2) \in \Delta$. Then set

$$f_1(x_1, x_2) = q_{a, \delta + 1}(x_1, x_2) = \begin{cases} f(x_1, x_2) + 1 & , (x_1, x_2) \in \Delta \\ \delta(x_1) + 1 & , \text{otherwise} \end{cases}$$

We construct a second function

$$f_2(x_1, x_2) = \begin{cases} 0 & , (x_1, x_2) \in \Delta \\ f(x_1, x_2) + 1 & , \text{otherwise} \end{cases}$$

It is readily verified that $f_2(x_1, x_2) = u(p_\Delta(x_2 + 1, x_1))$ for some unary $u$. Now $f_2(x_1, x_2) < f_1(x_1, x_2)$ and $f_1, f_2 \in \mathcal{C}$. Clearly

$$f(x_1, x_2) = u(p_\Delta(f_1(x_1, x_2), f_2(x_1, x_2)))$$

for some unary $u$. This shows $f \in \mathcal{C}$ and so $\langle T_1 \rangle \subseteq \mathcal{C}$ as $f \in T_1$ was arbitrary.

We shall see that $\text{Pol}(T_1)$ is also finitely generated over $\mathcal{O}^{(1)}$. Moreover, for countable $X$ it is a Borel set in the topology yet to be defined. Our explicit description $\text{Pol}(T_1)$ holds for all infinite $X$ of regular cardinality, but is interesting only if there are not too many other maximal clones containing $\mathcal{O}^{(1)}$. By Fact 2 this is at least the case for $X$ countably infinite or weakly compact.

1.3. **Notation.** For a set of functions $\mathcal{F}$ we shall denote the smallest clone containing $\mathcal{F}$ by $\langle \mathcal{F} \rangle$. By $\mathcal{F}^{(n)}$ we refer to the set of $n$-ary functions in $\mathcal{F}$.

We call the projections which every clone contains $\pi^n_i$ where $n \geq 1$ and $1 \leq i \leq n$. If $f \in \mathcal{O}^{(n)}$ is an $n$-ary function, it sends $n$-tuples of elements of $X$ to $X$ and we write $(x_1, ..., x_n)$ for these tuples unless otherwise stated as in $f(x, y, z)$; this is the only place where we do not stick to set-theoretical notation (according to which we would have to write $(x_0, ..., x_{n-1})$). The set
\{1, ..., n\} of indices of \(n\)-tuples will play an important role and we write \(N\) for it. We denote the set-theoretical complement of a subset \(A \subseteq N\) in \(N\) by \(-A\). We identify the set \(X^n\) of \(n\)-tuples with the set of functions from \(N\) to \(X\), so that if \(A \subseteq N\) and \(a : A \rightarrow X\) and \(b : -A \rightarrow X\) are partial functions, then \(a \cup b\) is an \(n\)-tuple. Sometimes, if the arity of \(f \in \mathcal{O}\) has not yet been given a name, we refer to that arity by \(n_f\).

If \(a \in X^n\) is an \(n\)-tuple and \(1 \leq k \leq n\) we write \(\langle a \rangle_k^n\) or only \(a_k\) for the \(k\)-th component of \(a\). For \(c \in X\) and \(J\) an index set we write \(c^J\) for the \(J\)-tuple with constant value \(c\). The order relation \(\leq\) on \(X\) induces the pointwise partial order on the set of \(J\)-tuples of elements of \(X\) for any index set \(J\): For \(x, y \in X^J\) we write \(x \leq y\) iff \(x_j \leq y_j\) for all \(j \in J\). Consequently we also denote the induced pointwise partial order of \(\mathcal{O}(n)\) by \(\leq\), so that for \(f, g \in \mathcal{O}(n)\) we have \(f \leq g\) iff \(f(x) \leq g(x)\) for all \(x \in X^n\). Whenever we state that a function \(f \in \mathcal{O}(n)\) is monotone, we mean it is monotone with respect to \(\leq\): \(f(x) \leq f(y)\) whenever \(x \leq y\). We denote the power set of \(X\) by \(\mathcal{P}(X)\). The element \(0 \in X\) is the smallest element of \(X\).

2. Properties of clones above \(\mathcal{U}\) and the clone \(Pol(T_1)\)

2.1. What \(\langle T_1 \rangle\) is. We start by proving that the almost unary clone \(\mathcal{U}\) is a so-called binary clone, that is, it is generated by its binary part. Thus, when investigating \([\mathcal{U}, Pol(T_1)]\), we are in fact dealing with an interval of the form \([\langle C(2) \rangle, Pol(\langle C(2) \rangle)]\) for \(C\) a clone.

**Lemma 5.** The binary almost unary functions generate all almost unary functions. That is, \(\langle T_1 \rangle = \mathcal{U}\).

**Proof.** Trivially, \(\langle T_1 \rangle \subseteq \mathcal{U}\). Now we prove by induction that \(\mathcal{U}^{(n)} \subseteq \langle T_1 \rangle\) for all \(n \geq 1\). This is obvious for \(n = 1, 2\). Assume we have \(\mathcal{U}^{(k)} \subseteq \langle T_1 \rangle\) for all \(k < n\) and take any function \(f \in \mathcal{U}^{(n)}\). Say without loss of generality that \(f(x_1, ..., x_n) \leq \gamma(x_1)\) for some \(\gamma \in \mathcal{O}(1)\). We will use the function \(p_\Delta \in T_1\) to code two variables into one and then use the induction hypothesis. Define

\[
g_i(x_1, ..., x_{n-2}, z) = \begin{cases} f(x_1, ..., x_{n-2}, (p_\Delta^{-1}(z))^2, (p_\Delta^{-1}(z))^2) & , z \in p_\Delta[X^2] \setminus \{0\} \\ x_1 & , \text{otherwise} \end{cases}
\]

The function is an element of \(\mathcal{U}^{(n-1)}\) as it is bounded by \(\max(x_1, \gamma(x_1))\). Intuitively, \(g_i\) does the following: If \(z \neq 0\) and in the range of \(p_\Delta\), then \(g_i\) imagines a pair \((x_{n-1}, x_n)\) to be coded into \(z\) via \(p_\Delta\). It reconstructs the pair \((x_{n-1}, x_n)\) and calculates \(f(x_1, ..., x_n)\). If \(z = 0\) or not in the range of \(p_\Delta\), then \(g\) knows there is no information in \(z\); it simply forgets about the tuple
In order to use the defined notions more freely, we define the empty set to be empty.

**Definition 7.**

The function $g_2$ does exactly the same as $g_1$ but assumes the pair $(x_{n-1}, x_n)$ to be coded into $z$ in wrong order, namely as $(x_n, x_{n-1})$, plus it cares for the diagonal. Now consider $h(x_1, \ldots, x_n) = g_2(g_1(x_1, \ldots, x_{n-2}, p\Delta(x_{n-1}, x_n)), x_2, \ldots, x_{n-2}, p\Delta'(x_n, x_{n-1})).$

All functions which occur in $h$ are almost unary with at most $n - 1$ variables. We claim that $h = f$. Indeed, if $x_{n-1} < x_n$, then $p\Delta(x_{n-1}, x_n) \neq 0$ and $g_1$ yields $f$. But $p\Delta'(x_n, x_{n-1}) = 0$ and so $g_2$ returns $g_1 = f$. If on the other hand $x_n \leq x_{n-1}$, then $p\Delta(x_{n-1}, x_n) = 0$ and $g_1 = x_1$, whereas $p\Delta'(x_n, x_{n-1}) \neq 0$, which implies $g_2 = f(g_1, x_2, \ldots, x_n) = f(x_1, \ldots, x_n).$ \hfill \Box

The following lemma will be crucial for our investigation of clones containing $T_1$.

**Corollary 6.** Let $\mathcal{C}$ be a clone containing $T_1$. Then $\mathcal{C}$ is downward closed, that is, if $f \in \mathcal{C}$, then also $g \in \mathcal{C}$ for all $g \leq f$.

**Proof.** If $f \in \mathcal{C}(n)$ and $g \in \mathcal{C}(n)$ with $g \leq f$ are given, define $h_g(x_1, \ldots, x_{n+1}) = \min(g(x_1, \ldots, x_n), x_{n+1})$. Then $h_g \leq x_{n+1}$ and consequently, $h_g \in \langle T_1 \rangle \subseteq \mathcal{C}$. Now $g = h_g(x_1, \ldots, x_n, f(x_1, \ldots, x_n)) \in \mathcal{C}$. \hfill \Box

2.2. **Wildness of functions.** We have seen in the last section that the interval $[\mathcal{U}, \mathcal{O}]$ is about growth of functions as all clones in that interval are downward closed. But mind we are not talking about how rapidly functions are growing in the sense of polynomial growth, exponential growth and so forth since we are considering clones modulo $\mathcal{O}(1)$ (and so we can make functions as steep as we like); the growth of a function will be determined by which of its variables are responsible for the function to obtain many values. The following definition is due to M. Goldstern and S. Shelah \[5]. Recall that $N = \{1, \ldots, n\}$.

**Definition 7.** Let $f \in \mathcal{O}(n)$. We call a set $\emptyset \neq A \subseteq N$ $f$-strong iff for all $a \in X^A$ the set $\{f(a \cup x) : x \in X^{-A}\}$ is small. $A$ is $f$-weak iff it is not $f$-strong. In order to use the defined notions more freely, we define the empty set to be $f$-strong iff $f$ has small range.
Thus, a set of indices of variables of $f$ is strong iff $f$ is bounded whenever those variables are. For example, a function is almost unary iff it has a one-element strong set. Here, we shall rather think in terms of the complements of weak sets.

**Definition 8.** Let $f \in O(n)$ and let $A \subseteq N$ and $a \in X^{-A}$. We say $A$ is $(f, a)$-wild iff the set $\{f(a \cup x) : x \in X^A\}$ is large. The set $A$ is called $f$-wild iff there exists $a \in X^{-A}$ such that $A$ is $(f, a)$-wild. We say that $A$ is $f$-insane iff $A$ is $(f, a)$-wild for all $a \in X^{-A}$. The set $N$ itself we call $f$-wild and $f$-insane iff $f$ is unbounded.

Observe that if $A \subseteq B \subseteq N$ and $A$ is $f$-wild, then $B$ is $f$-wild as well. Obviously, $A \subseteq N$ is $f$-wild iff $-A$ is $f$-weak. It is useful to state the following trivial criterion for a function to be almost unary.

**Lemma 9.** Let $n \geq 2$ and $f \in O^{(n)}$. $f$ is almost unary iff there exists a subset of $N$ with $n - 1$ elements which is not $f$-wild.

**Proof.** If $f$ is almost unary, then there is a one-element $f$-strong subset of $N$ and the complement of that set is not $f$-wild. If on the other hand there exists $k \in N$ such that $N \setminus \{k\}$ is not $f$-wild, then $\{k\}$ is $f$-strong and so $f$ is almost unary. □

We will require the following fact from [5].

**Fact 10.** If $f \in \text{Pol}(T_1)^{(n)}$ and $A_1, A_2 \subseteq N$ are $f$-wild, then $A_1 \cap A_2 \neq \emptyset$.

We observe that the converse of this statement holds as well.

**Lemma 11.** Let $f \in O^{(n)}$ be any $n$-ary function. If all pairs of $f$-wild subsets of $N$ have a nonempty intersection, then $f \in \text{Pol}(T_1)$.

**Proof.** Let $g_1, \ldots, g_n \in T_1$ be given and set $A_1 = \{k \in N : \exists \gamma \in O^{(1)} \ (g_k(x_1, x_2) \leq \gamma(x_1))\}$ and $A_2 = -A_1$. Since $A_1 \cap A_2 = \emptyset$ either $A_1$ or $A_2$ cannot be $f$-wild. Thus $f(g_1, \ldots, g_n)$ is bounded by a unary function of $x_2$ in the first case and by a unary function of $x_1$ in the second case. □

The equivalence yields a first description of $\text{Pol}(T_1)$ with an interesting consequence.

**Theorem 12.** A function $f \in O^{(n)}$ is an element of $\text{Pol}(T_1)$ iff all pairs of $f$-wild subsets of $N$ have a nonempty intersection.

We show now that for countable $X$, this description implies that $\text{Pol}(T_1)$ is a Borel set with respect to the natural topology on $O$. We do not explain
the basic notions of descriptive set theory. The reader not familiar with these notions is advised to either skip this part and proceed directly to the next section or to consult [6].

Equip $X = \omega$ with the discrete topology. Then the product space $\mathcal{N} = \omega^\omega = \mathcal{O}^{(1)}$ is the so-called Baire space. It is obvious that $\mathcal{O}^{(n)} = \omega^{\omega^n}$ is homeomorphic to $\mathcal{N}$. Thus, $\mathcal{O} = \bigcup_{n=1}^{\infty} \mathcal{O}^{(n)}$ is the sum of $\omega$ copies of $\mathcal{N}$.

**Theorem 13.** Let $X$ be countably infinite. Then $\text{Pol}(T_1)$ is a Borel set in $\mathcal{O}$.

**Proof.** By the preceding theorem, 

$$\text{Pol}(T_1)^{(n)} = \{ f \in \mathcal{O}^{(n)} : \forall A, B \subseteq N (A, B \text{ f-wild} \rightarrow A \cap B \neq \emptyset) \}$$

There are no (only finite) quantifiers in this definition except for those which might occur in the predicate of wildness. Now

$$A \subseteq N \text{ f-wild} \iff \exists a \in X^{-A} \forall k \in X \exists b \in X^A (f(a \cup b) > k)$$

All quantifiers range over countable sets so that $\text{Pol}(T_1)$ is $\Sigma^0_3$. □

The preceding theorem shows that $\text{Pol}(T_2)$ is much more complicated than $\text{Pol}(T_1)$, as M. Goldstern observed the following [3].

**Fact 14.** Let $X$ be countably infinite. Then $\text{Pol}(T_2)$ is a $\Pi^1_1$-complete set in $\mathcal{O}$.

2.3. **What wildness means.** We wish to compare the wildness of functions. Write $S_N$ for the set of all permutations on $N$.

**Definition 15.** For $f, g \in \mathcal{O}^{(n)}$ we say that $f$ is as wild as $g$ and write $f \sim_W g$ iff there exists a permutation $\pi \in S_N$ such that $A$ is $f$-wild if and only if $\pi[A]$ is $g$-wild for all $A \subseteq N$. Moreover, $g$ is at least as wild as $f$ ($f \leq_W g$) iff there is a permutation $\pi \in S_N$ such that for all $f$-wild subsets $A \subseteq N$ the image $\pi[A]$ of $A$ under $\pi$ is $g$-wild.

**Lemma 16.** $\sim_W$ is an equivalence relation and $\leq_W$ a quasiorder extending $\leq$ on the set of $n$-ary functions $\mathcal{O}^{(n)}$.

**Proof.** We leave the verification of this to the reader. □

**Lemma 17.** Let $f, g \in \mathcal{O}^{(n)}$. Then $f \sim_W g$ iff $f \leq_W g$ and $g \leq_W f$.

**Proof.** It is clear that $f \leq_W g$ (and $g \leq_W f$) if $f \sim_W g$. Now assume $f \leq_W g$ and $g \leq_W f$. Then there are $\pi_1, \pi_2 \in S_N$ which take $f$-wild and $g$-wild subsets of $N$ to $g$-wild and $f$-wild sets, respectively.

Set $\pi = \pi_2 \circ \pi_1$. Then $A$ is $f$-wild iff $\pi[A]$ is $f$-wild for any subset $A$ of $N$: If $A$ is $f$-wild, then $\pi_1[A]$ is $g$-wild, then $\pi_2[\pi_1[A]] = \pi[A]$ is $f$-wild. If on the
other hand \( \pi[A] \) is \( f \)-wild, then take \( k \geq 1 \) such that \( \pi^k = id_N \) and observe that \( \pi^{k-1} \circ \pi[A] = \pi^k[A] = A \) is \( f \)-wild.

Now we see that \( A \) is \( f \)-wild iff \( \pi_1[A] \) is \( g \)-wild for all \( A \subseteq N \): If \( \pi_1[A] \) is \( g \)-wild, then so is \( \pi_2 \circ \pi_1[A] = \pi[A] \) and so is \( A \) by the preceding observation. Hence, the permutation \( \pi_1 \) shows that \( f \sim_W g \).

\[ \tag*{\Box} \]

**Corollary 18.** Let \( n \geq 1 \). Then \( \leq_W/\sim_W \) is a partial order on the \( \sim_W \)-equivalence classes of \( \mathcal{O}^{(n)} \).

**Notation 19.** Let \( f \in \mathcal{O}^{(n)} \). By \( \langle f \rangle_{T_1} \) we mean \( \langle \{ f \} \cup T_1 \rangle \) from now on. \( \langle f \rangle_{T_1} \) is the smallest clone containing \( f \) as well as all almost unary functions.

We are aiming for the following theorem which tells us why we invented wildness.

**Theorem 20.** Let \( f, g \in \mathcal{O}^{(n)} \). If \( f \leq_W g \), then \( f \in \langle g \rangle_{T_1} \). In words, if \( g \) is at least as wild as \( f \), then it generates \( f \) modulo \( T_1 \).

**Corollary 21.** Let \( f, g \in \mathcal{O}^{(n)} \). If \( f \sim_W g \), then \( \langle f \rangle_{T_1} = \langle g \rangle_{T_1} \).

We split the proof of Theorem 20 into a sequence of lemmas. In the next lemma we see that it does not matter which \( a \in X^{-A} \) makes a set \( A \subseteq N \) wild.

**Lemma 22.** Let \( g \in \mathcal{O}^{(n)} \). Then there exists \( g' \in \langle g \rangle^{(n)}_{T_1} \) such that for all \( A \subseteq N \) the following holds: If \( A \) is \( g \)-wild, then \( A \) is \( (g',0^{-A}) \)-wild.

**Proof.** Fix for all \( g \)-wild \( A \subseteq N \) a tuple \( a_A \in X^{-A} \) such that \( \{ g(x \cup a_A) : x \in X^A \} \) is large. For an \( n \)-tuple \( (x_1, ..., x_n) \) write \( P = P(x_1, ..., x_n) = \{ l \in N : x_l \neq 0 \} \) for the set of indices of positive components in the tuple. Define for \( 1 \leq i \leq n \) functions

\[
\gamma_i(x_1, ..., x_n) = \begin{cases} x_i & \text{if } x_i \neq 0 \lor P(x_1, ..., x_n) \text{ not } g \text{-wild} \\ (a_P)_i & \text{otherwise} \end{cases}
\]

In words, if the set \( P \) of indices of positive components in \( (x_1, ..., x_n) \) is a wild set, then the \( \gamma_i \) leave those positive components alone and send the zero components to the respective values making \( P \) wild. Otherwise, they act just like projections. It is obvious that \( \gamma_i \) is almost unary, \( 1 \leq i \leq n \). Set \( g' = g(\gamma_1, ..., \gamma_n) \in \langle g \rangle_{T_1} \). To prove that \( g' \) has the desired property, let \( A \subseteq N \) be \( g \)-wild. Choose any minimal \( g \)-wild \( A' \subseteq A \). Then by the definition of wildness the set \( \{ g(x \cup a_A) : x \in X^{A'} \} \) is large. Take a large \( B \subseteq X^{A'} \) such that the sequence \( (g(x \cup a_A) : x \in B) \) is one-one. Select further a large \( C \subseteq B \) such that each component in the sequence of tuples \( (x : x \in C) \) is either
constant or injective and such that 0 does not occur in any of the injective components (it is a simple combinatorial fact that this is possible). If one of the components were constant, then \( A' \) would not be minimal \( g \)-wild; hence, all components are injective. Now we have

\[
|X| = |\{g(x \cup a_A') : x \in C\}|
\]

\[
= |\{g'(x \cup 0^{-A'}) : x \in C\}| \leq |\{g'(x \cup 0^{-A}) : x \in X^A\}|
\]

and so \( A \) is \((g',0^{-A})\)-wild. \( \square \)

We prove that we can assume functions to be monotone.

**Lemma 23.** Let \( g \in \sigma^{(n)} \). Then there exists \( g'' \in (g)_{T_1}^{(n)} \) such that \( g \leq g'' \) and \( g'' \) is monotone with respect to the pointwise order \( \leq \).

**Proof.** We will define a mapping \( \gamma \) from \( X^n \) to \( X^n \) such that \( \gamma_i = \pi_i^n \circ \gamma \) is almost unary for \( 1 \leq i \leq n \) and such that \( g'' = g \circ \gamma \) has the desired property.

We fix for every \( g \)-wild \( A \subseteq N \) a sequence \((\alpha^A_\xi)_{\xi \in X}\) of elements of \( X^n \) so that all components of \( \alpha^A_\xi \) which lie not in \( A \) are constant and so that \((g(\alpha^A_\xi))_{\xi \in X}\) is monotone and unbounded.

Let \( x \in X^n \). The order type of \( x \) is the unique \( n \)-tuple \((j_1, ..., j_n)\) of indices in \( N \) such that \( \{j_1, ..., j_n\} = \{1, ..., n\} \) and such that \( x_{j_i} \leq ... \leq x_{j_n} \) and such that \( j_k < j_{k+1} \) whenever \( x_{j_k} = x_{j_{k+1}} \). Let \( 1 \leq k \leq n \) be the largest element with the property that the set \( \{j_k, ..., j_n\} \) is \( g \)-wild. We call the set \( \{j_k, ..., j_n\} \) the pushing set \( Push(x) \) and \( \{j_1, ..., j_{k-1}\} \) the holding set of \( x \) with respect to \( g \).

We define by transfinite recursion

\[
\gamma : \quad X^n \to X^n
\]

\[
x \to \alpha^\text{Push}(x)_{\lambda(x)}
\]

where

\[
\lambda(x) = \min\{\xi : g(\alpha^\text{Push}(x)_\xi) \geq \sup(\{g''(y) : y \leq x\} \cup \{g(x)\})\}.
\]

This looks worse than it is: We simply map \( x \) to the first element of the sequence \((\alpha^\text{Push}(x))_{\xi \in X}\) such that all values of \( g'' \) already defined as well as \( g(x) \) are topped. By definition, \( g'' = g \circ \gamma \) is monotone and \( g \leq g'' \). It only remains to prove that all \( \gamma_i, 1 \leq i \leq n \), are almost unary to see that \( g'' \in (g)_{T_1} \).

Suppose not, and say that \( \gamma_k \) is not almost unary for some \( 1 \leq k \leq n \). Then there exists a value \( c \in X \) and a sequence of \( n \)-tuples \((\beta_\xi)_{\xi \in X}\) with constant value \( c \) in the \( k \)-th component such that \((\gamma_k(\beta_\xi))_{\xi \in X}\) is unbounded. Since there exist only finitely many order types of \( n \)-tuples, we can assume that all \( \beta_\xi \) have the same order type \((j_1, ..., j_n)\); say without loss of generality
$(j_1, \ldots, j_n) = (1, \ldots, n)$. Then all $\beta_\xi$ have the same pushing set $\text{Push}(\beta)$ of indices. If $k$ was an element of the holding set of the tuples $\beta_\xi$, then $(\gamma_k(\beta_\xi) : \xi \in X)$ would be constant so that $k$ must be in $\text{Push}(\beta)$. Clearly, $(\lambda(\beta_\xi))_{\xi \in X}$ has to be unbounded as otherwise $(\gamma_k(\beta_\xi))_{\xi \in X}$ would be bounded. Since by definition the value of $\lambda$ increases only when it is necessary to keep $g \leq g''$, the set $\{g(y) : \exists \xi \in X(y \leq \beta_\xi)\}$ is unbounded. But because of the order type of the $\beta_\xi$, whenever $i \leq k$, then we have $(\beta_\xi)_i \leq c$ for all $\xi \in X$ so that the components of the $\beta_\xi$ with index in the set $\{1, \ldots, k\}$ are bounded. Thus, $\{k + 1, \ldots, n\}$ is $g$-wild, contradicting the fact that $k$ is in the pushing set $\text{Push}(\beta)$.

$\square$

In a next step we shall see that modulo $T_1$, wildness is insanity.

**Lemma 24.** Let $g \in \mathcal{O}^{(n)}$. Then there exists $g'' \in \langle g \rangle_{T_1}^{(n)}$ such that $g''$ is monotone and for all $A \subseteq N$ the following holds: If $A$ is $g$-wild, then $A$ is $g''$-insane.

*Proof.* Let $g' \in \langle g \rangle_{T_1}^{(n)}$ be provided by Lemma 22 and make a monotone $g''$ out of it with the help of the preceding lemma. We claim that $g''$ already has both desired properties. To prove this, consider an arbitrary $g$-wild $A \subseteq N$. By construction of $g'$, $A$ is $(g', 0^{-A})$-wild and so it is also $(g'', 0^{-A})$-wild as $g' \leq g''$. But $0^{-A} \leq a$ for all $a \in X^{-A}$; hence the fact that $g''$ is monotone implies that $A$ is $(g, a)$-wild for all $a \in X^{-A}$ which means exactly that $A$ is $g''$-insane. $\square$

**Lemma 25.** Let $f, g \in \mathcal{O}^{(n)}$. If $f \leq_W g$, then there exists $h \in \langle g \rangle_{T_1}^{(n)}$ such that $f \leq h$.

*Proof.* Without loss of generality, we assume that the permutation $\pi \in S_N$ taking $f$-wild subsets of $N$ to $g$-wild sets is the identity on $N$. We take $g'' \in \langle g \rangle_{T_1}$ according to the preceding lemma. We wish to define $\gamma \in \mathcal{O}^{(1)}$ with $f \leq \gamma \circ g''$. For $x \in X$ write $U_x = g''^{-1}([x])$ for the preimage of $x$ under $g''$. Now set

$$\gamma(x) = \begin{cases} \sup\{f(y) : y \in U_x\} & U_x \neq \emptyset \\ 0 & \text{otherwise} \end{cases}$$

We claim that $\gamma$ is well-defined, that is, the supremum in its definition always exists in $X$. For suppose there is an $x \in X$ such that the set $\{f(y) : y \in U_x\}$ is unbounded. Choose a large subset $B \subseteq U_x$ making the sequence $(f(y) : y \in B)$ one-one. Take further a large $C \subseteq B$ so that all components in the sequence $(y : y \in C)$ are either one-one or constant. Set $A = \{i \in N : (y_i : i \in$
$C$) is injective}. Obviously, $A$ is $f$-wild; therefore it is $g''$-insane. Since $g''$ is also monotone, the set $\{g''(y) : y \in C\}$ is large, contradicting the fact that $g''$ is constant on $U_x$. Thus, $\gamma$ is well-defined and clearly $f \leq h \in \langle g \rangle_{T_1}$ where $h = \gamma \circ g''$. \hfill $\square$

**Proof of Theorem 20.** The assertion is an immediate consequence of the preceding lemma and the fact that all clones above $\mathcal{U}$ are downward closed. \hfill $\square$

**Remark 26.** Unfortunately, the converse does not hold: If $f, g \in \mathcal{O}(n)$ and $f \in \langle g \rangle_{T_1}$ then it need not be true that $f \leq_W g$. We will see an example at the end of the section.

### 2.4. $\text{med}_3$ and $T_1$ generate $\text{Pol}(T_1)$.

**Definition 27.** For all $n \geq 1$ and all $1 \leq k \leq n$ we define a function

$$m^n_k(x_1, ..., x_n) = x_{j_k} \quad \text{if} \quad x_{j_1} \leq ... \leq x_{j_n}.$$  

For example, $m^n_n$ is the maximum function $\max_n$ and $m^n_1$ the minimum function $\min_n$ in $n$ variables. Note that $\min_n \in \text{Pol}(T_1)$ (it is even almost unary) but $\max_n \notin \text{Pol}(T_1)$ (and hence $\langle \max_n \rangle_{T_1} = \mathcal{O}$). If $n$ is an odd number then we call $m^n_{n+1}$ the $n$-th median function and denote this function by $\text{med}_n$.

For fixed odd $n$ it is easily verified (check the wild sets and apply Theorem 12) that $\text{med}_n$ it is the largest of the $m^n_k$ which still lies in $\text{Pol}(T_1)$: $m^n_k \in \text{Pol}(T_1)$ iff $k \leq \frac{n+1}{2}$. It is for this reason that we are interested in the median functions on our quest for a nice generating system of $\text{Pol}(T_1)$. As a consequence of the following fact from [7] it does not matter which of the median functions we consider.

**Fact 28.** Let $k, n \geq 3$ be odd natural numbers. Then $\text{med}_k \in \langle \{\text{med}_n\} \rangle_{n}$.

In other words, a clone contains either no median function or all median functions.

The following lemma states that within the restrictions of functions of $\text{Pol}(T_1)$ (Fact 10), we can construct functions of arbitrary wildness with the median.

**Lemma 29.** Let $n \geq 1$ and let $\mathcal{A} = \{A_1, ..., A_k\} \subseteq \mathcal{P}(N)$ be a set of subsets of $N$ with the property that $A_i \cap A_j \neq \emptyset$ for all $1 \leq i, j \leq k$. Then there exists monotone $t_{\mathcal{A}} \in \langle \{\text{med}_3\} \rangle_{n}$ such that all members of $\mathcal{A}$ are $t_{\mathcal{A}}$-insane.

**Proof.** We prove this by induction over the size $k$ of $\mathcal{A}$. If $\mathcal{A}$ is empty there is nothing to show. If $k = 1$, we can set $t_{\mathcal{A}} = \pi^n_i$, where $i$ is an
arbitrary element of $A_1$. Then $A_1$ is obviously $t_{\mathcal{A}}$-insane. If $k = 2$, then define $t_{\mathcal{A}} = \pi_i^n$, where $i \in A_1 \cap A_2$ is arbitrary. Clearly, both $A_1$ and $A_2$ are $t_{\mathcal{A}}$-insane. Finally, assume $k \geq 3$. By induction hypothesis, there exist monotone terms $t_{\mathcal{B}}, t_{\mathcal{C}}, t_{\mathcal{D}} \in \langle\{\text{med}_3\}\rangle^{(n)}$ for the sets $\mathcal{B} = \{A_1, \ldots, A_{k-1}\}$, $\mathcal{C} = \{A_1, \ldots, A_{k-2}, A_k\}$ and $\mathcal{D} = \{A_{k-1}, A_k\}$ such that all sets in $\mathcal{B}$ (and $\mathcal{C}, \mathcal{D}$ respectively) are $t_{\mathcal{B}}$-insane ($t_{\mathcal{C}}$-insane, $t_{\mathcal{D}}$-insane). Set

$$t_{\mathcal{A}} = \text{med}_3(t_{\mathcal{B}}, t_{\mathcal{C}}, t_{\mathcal{D}}).$$

Then each $A_i$ is insane for two of the three terms in med$_3$. Thus, if we fix the variables outside $A_i$ to arbitrary values, then at least two of the three subterms in med$_3$ are still unbounded and so is $t_{\mathcal{A}}$ by the monotonicity of its subterms. Hence, every $A_i$ is $t_{\mathcal{A}}$-insane, $1 \leq i \leq k$. Obviously $t_{\mathcal{A}}$ is monotone. □

**Lemma 30.** Let $f \in \text{Pol}(T_1)^{(n)}$. Then there exists $t_f \in \langle\{\text{med}_3\}\rangle$ such that $f \leq_W t_f$.

**Proof.** Write $\mathcal{A} = \{A_1, \ldots, A_k\}$ for the set of $f$-wild subsets of $N$. By Fact 10, $A_i \cap A_j \neq \emptyset$ for all $1 \leq i, j \leq k$. Apply the preceding lemma to $\mathcal{A}$. □

**Theorem 31.** $\text{Pol}(T_1) = \langle\text{med}_3\rangle_{T_1}$.

**Proof.** It is clear that $\text{Pol}(T_1) \supseteq \langle\text{med}_3\rangle_{T_1}$. On the other hand we have just seen that if $f \in \text{Pol}(T_1)$, then there exists $t_f \in \langle\{\text{med}_3\}\rangle$ such that $f \leq_W t_f$, whence $f \in \langle\text{med}_3\rangle_{T_1}$. □

**Corollary 32.** $\text{Pol}(T_1)$ is the $\leq$-downward closure of the clone generated by med$_3$ and the unary functions $\mathcal{O}^{(1)}$.

**Proof.** Given $f \in \text{Pol}(T_1)$, by Lemma 30 there exists $t_f \in \langle\{\text{med}_3\}\rangle$ such that $f \leq_W t_f$. By Lemma 25, $t_f$ is monotone and each $t_f$-wild set is in fact even $t_{\mathcal{A}}$-insane. Now one follows the proof of Lemma 25 to obtain $\gamma \in \mathcal{O}^{(1)}$ such that $f \leq \gamma \circ t_f$. □

**Corollary 33.** $\text{Pol}(T_1) = \langle\{\text{med}_3, p_\Delta\} \cup \mathcal{O}^{(1)}\rangle$. In particular, $\text{Pol}(T_1)$ is finitely generated over the unary functions.

**Proof.** Remember that $\langle\{p_\Delta\} \cup \mathcal{O}^{(1)}\rangle = \langle T_1 \rangle$ (Fact 4) and apply Theorem 31. □

Now we can give the example promised in Remark 26. Set

$$g(x_1, \ldots, x_4) = \text{med}_3(x_1, x_2, x_3)$$

and

$$f(x_1, \ldots, x_4) = \text{med}_5(x_1, x_1, x_2, x_3, x_4).$$
It is obvious that \( \langle g \rangle_{T_1} = \langle \text{med}_3 \rangle_{T_1} = \text{Pol}(T_1) \). Next observe that \( \langle f \rangle_{T_1} \subseteq \langle \text{med}_5 \rangle_{T_1} = \text{Pol}(T_1) \) and that \( f(x_1, x_2, x_3, x_3) = \text{med}_3 \) which implies \( \text{Pol}(T_1) = \langle \text{med}_3 \rangle_{T_1} \subseteq \langle f \rangle_{T_1} \). Thus, \( \langle g \rangle_{T_1} = \langle f \rangle_{T_1} \). Consider on the other hand the 2-element wild sets of the two functions: Exactly \( \{1, 2\}, \{1, 3\} \) and \( \{2, 3\} \) are \( g \)-wild, and \( \{1, 2\}, \{1, 3\} \) are the wild sets of two elements for \( f \). Now the intersection of first group is empty, whereas the one of the second group is not; so there is no permutation of the set \( \{1, 2, 3, 4\} \) which takes the first group to the second or the other way. Hence, neither \( f \leq_W g \) nor \( g \leq_W f \).

3. The interval \([\mathcal{U}, \mathcal{E}]\)

3.1. A chain in the interval. Now we shall show that the open interval \((\langle T_1 \rangle, \text{Pol}(T_1))\) is not empty by exhibiting a countably infinite descending chain therein with intersection \( \mathcal{U} \).

**Notation 34.** For a natural number \( n \geq 2 \), we write \( \mathcal{M}_n = \langle \{m_2^n\} \cup T_1 \rangle \).

Observe that since \( m_2^2 = \text{max}_2 \notin \text{Pol}(T_1) \), Fact 1 implies that \( \mathcal{M}_2 = \mathcal{E} \). Moreover, \( m_3^2 = \text{med}_3 \) and hence, \( \mathcal{M}_3 = \text{Pol}(T_1) \).

**Lemma 35.** Let \( n \geq 2 \). Then \( \mathcal{M}_n^{(k)} = \mathcal{U}^{(k)} \) for all \( 1 \leq k < n \). That is, all functions in \( \mathcal{M}_n \) of arity less than \( n \) are almost unary.

**Proof.** Given \( n, k \) we show by induction over terms that if \( t \in \mathcal{M}_n^{(k)} \), then \( t \) is almost unary. To start the induction we note that the only \( k \)-ary functions in the generating set of \( \mathcal{M}_n \) are almost unary. Now assume \( t = f(t_1, t_2) \), where \( f \in T_1 \) and \( t_1, t_2 \in \mathcal{M}_n^{(k)} \). By induction hypothesis, \( t_1 \) and \( t_2 \) are almost unary and so is \( t \) as the almost unary functions are closed under composition. Finally, say \( t = m_2^n(t_1, \ldots, t_n) \), where the \( t_i \) are almost unary \( k \)-ary functions, \( 1 \leq i \leq n \). Since \( k < n \), there exist \( i, j \in N \) with \( i \neq j \), \( l \in \{1, \ldots, k\} \), and \( \gamma, \delta \in \mathcal{O}^{(1)} \) such that \( t_i \leq \gamma(x_l) \) and \( t_j \leq \delta(x_l) \). Then, \( t \leq \max(\gamma, \delta)(x_l) \) and so \( t \) is almost unary as well. \( \square \)

**Corollary 36.** If \( n \geq 2 \), then \( m_2^n \notin \mathcal{M}_{n+1} \). Consequently, \( \mathcal{M}_n \notin \mathcal{M}_{n+1} \).

**Lemma 37.** If \( n \geq 2 \), then \( m_2^{n+1} \in \mathcal{M}_n \). Consequently, \( \mathcal{M}_{n+1} \subseteq \mathcal{M}_n \).

**Proof.** Set \[ f(x_1, \ldots, x_{n+1}) = m_2^n(x_1, \ldots, x_n) \in \mathcal{M}_n. \]

Then every \( n \)-element subset of \( \{1, \ldots, n+1\} \) is \( f \)-wild. Hence, \( m_2^{n+1} \leq_W f \) and so \( m_2^{n+1} \in \langle f \rangle_{T_1} \subseteq \mathcal{M}_n \). \( \square \)
Theorem 38. The sequence \((\mathcal{M}_n)_{n \geq 2}\) forms a countably infinite descending chain:

\[
\mathcal{G} = \mathcal{M}_2 \supsetneq \mathcal{M}_3 = \text{Pol}(T_1) \supsetneq \mathcal{M}_4 \supsetneq \ldots \supsetneq \mathcal{M}_n \supsetneq \mathcal{M}_{n+1} \supsetneq \ldots
\]

Moreover,

\[
\bigcap_{n \geq 2} \mathcal{M}_n = \mathcal{U}.
\]

Proof. The first statement follows from Corollary 36 and Lemma 37. The second statement a direct consequence of Lemma 35. \(\square\)

3.2. Finally, this is the interval. We will now prove that there are no more clones in the interval \([\mathcal{U}, \mathcal{G}]\) than the ones we already exhibited. We first state a technical lemma.

Lemma 39. Let \(f \in \mathcal{O}^{(n)}\) be a monotone function such that all \(f\)-wild subsets of \(N\) are \(f\)-insane. Define for \(i, j \in N\) with \(i \neq j\) functions

\[
f^{(i,j)}(x_1, \ldots, x_n) = f(x_1, \ldots, x_{i-1}, x_j, x_{i+1}, \ldots, x_n)
\]

which replace the \(i\)-th by the \(j\)-th component and calculate \(f\). Then the following implications hold for all \(f\)-wild \(A \subseteq N\) and all \(i, j \in N\) with \(i \neq j\):

(i) If \(i \notin A\), then \(A\) is \(f^{(i,j)}\)-insane.

(ii) If \(j \in A\), then \(A\) is \(f^{(i,j)}\)-insane.

Proof. We have to show that if we fix the variables outside \(A\) to constant values, then \(f^{(i,j)}\) is still unbounded; because \(f\) is monotone, we can assume all values are fixed to 0. Fix a sequence \((\alpha_\xi : \xi \in X)\) of elements of \(X^n\) such that all components outside \(A\) are zero for all tuples of the sequence and such that \((f(\alpha_\xi) : \xi \in X)\) is unbounded. Define a sequence of \(n\)-tuples \((\beta_\xi : \xi \in X)\) by

\[
(\beta_\xi)^n_k = \begin{cases} 0, & k \notin A \\ \xi, & \text{otherwise} \end{cases}
\]

For each \(\xi \in X\) there exist a \(\lambda \in X\) such that \(\alpha_\xi \leq \beta_\lambda\). Then \(f(\alpha_\xi) \leq f(\beta_\lambda)\). In either of the cases (i) or (ii), \(f(\beta_\lambda) \leq f^{(i,j)}(\beta_\lambda)\). Thus, \((f^{(i,j)}(\beta_\xi) : \xi \in X)\) is unbounded. \(\square\)

Lemma 40. Let \(f \in \mathcal{O}^{(n)}\) not almost unary. Then there exists \(n_0 \geq 2\) such that \((f)_{T_1} = \langle m_2^{n_0} \rangle_{T_1}\).

Proof. We shall prove this by induction over the arity \(n\) of \(f\). If \(n = 1\), there are no not almost unary functions so there is nothing to show. Now assume our assertion holds for all \(1 \leq k < n\). We distinguish two cases:
First, consider \( f \) such that all \( f \)-wild subsets of \( N \) have size at least \( n - 1 \). Then \( f \sim_W m^n_2 \) and so \( \langle f \rangle_{T_1} = \langle m^n_2 \rangle_{T_1} \).

Now assume there exists an \( f \)-wild subset of \( N \) of size \( n - 2 \), say without loss of generality that \( \{2, \ldots, n-1\} \) is such a set. By Lemma 24 and Theorem 20 there exists a monotone \( \hat{f} \) with \( \langle f \rangle_{T_1} = \langle \hat{f} \rangle_{T_1} \) and with the property that all \( f \)-wild subsets of \( N \) are \( \hat{f} \)-insane. Since we could replace \( f \) by \( \hat{f} \), we assume that \( f \) is monotone and that all \( f \)-wild sets are \( f \)-insane.

Consider the \( f^{(i,j)} \) as defined in the preceding lemma. Formally, these functions are still \( n \)-ary, but in fact they depend only on \( n - 1 \) variables. Thus, all of the \( f^{(i,j)} \) which are not almost unary satisfy the induction hypothesis.

Set \( n_0 = \min \{ k : \exists i, j \in N \langle f^{(i,j)} \rangle_{T_1} = \langle m^k_2 \rangle_{T_1} \} \).

The minimum is well-defined: Because \( \{2, \ldots, n-1\} \) is \( f \)-insane, \( f^{(n,1)} \) is not almost unary so that it generates the same clone as some \( m^n_2 \) modulo \( T_1 \); thus, the set is not empty. Clearly, \( m^n_{2n} \in \langle f \rangle_{T_1} \). We show that \( m^n_{2n} \) is strong enough to generate \( f \). Since \( \mathcal{M}_n \subseteq \mathcal{M}_{n_0} \) for all \( n \geq n_0 \) we have \( f^{(i,j)} \in \langle m^n_{2n} \rangle_{T_1} \) for all \( i, j \in N \) with \( i \neq j \). Now define

\[
t(x_1, \ldots, x_n) = f^{(n,1)}(x_1, f^{(1,2)}, f^{(1,3)}, \ldots, f^{(1,n-1)}) \in \langle m^n_{2n} \rangle_{T_1}.
\]

We claim that \( f \leq_W t \). Indeed, let \( A \subseteq N \) be \( f \)-wild and whence \( f \)-insane by our assumption.

If \( 1 \notin A \), then \( A \) is \( f^{(1,j)} \)-insane for all \( 2 \leq j \leq n - 1 \) by the preceding lemma. So \( A \) is insane for all components in the definition of \( t \) except the first one. Hence, because \( f \) is monotone, \( A \) must be \( t \)-insane as otherwise \( f^{(n,1)} \) would be almost unary.

If \( 1 \in A \), then by the preceding lemma \( A \) is still \( f^{(1,j)} \)-insane whenever \( j \in A \). Thus, increasing the components with index in \( A \) increases the first component in \( t \) plus all subterms \( f^{(1,j)} \) with \( j \in A \); but by the definition of \( f^{(n,1)} \), that is the same as increasing the variables \( A \cup \{n\} \supseteq A \) in \( f \). Whence, \( A \) is \( t \)-insane.

This proves \( f \leq_W t \) and thus \( f \in \langle m^n_{2n} \rangle_{T_1} \).

So here it is, the interval and the end of our quest.

**Theorem 41.** Let \( \mathcal{C} \supseteq \mathcal{W} \) be a clone. Then there exists \( n \geq 2 \) such that \( \mathcal{C} = \mathcal{M}_n \).

**Proof.** Set

\[
n_{\mathcal{C}} = \min \{ n \geq 2 : \mathcal{M}_n \subseteq \mathcal{C} \}.
\]

Since \( \mathcal{C} \) contains a function which is not almost unary, the preceding lemma implies that the set over which we take the minimum is nonempty. Obviously,
$\mathcal{M}_{\emptyset} \subseteq \mathcal{C}$. Now let $f$ be an arbitrary function in $\mathcal{C}$ which is not almost unary. Then by the preceding lemma, there exists $n_0$ such that $\langle m_2^{n_0} \rangle_{T_1} = \langle f \rangle_{T_1}$. Clearly, $n_0 \geq n_\emptyset$ so that $f \in \mathcal{M}_{n_\emptyset} \subseteq \mathcal{M}_{\emptyset}$.

We state a lemma describing how the $k$-ary parts of the $\mathcal{M}_n$ for arbitrary $k$ relate to each other.

Lemma 42. Let $m > n \geq 2$ and $k \geq 2$. If $k \geq n$ (that is, if $\mathcal{M}_n^{(k)}$ is nontrivial), then $\mathcal{M}_n^{(k)} \supseteq \mathcal{M}_m^{(k)}$.

Proof. We know that $\mathcal{M}_n^{(k)} \supseteq \mathcal{M}_m^{(k)}$. To see the inequality of the two sets, observe that

$$f(x_1, \ldots, x_k) = m_2^n(x_1, \ldots, x_n)$$

is an element of $\mathcal{M}_n^{(k)}$ but definitely not one of $\mathcal{M}_m^{(k)}$.

Corollary 43. Let $k \geq 2$. Then

$$\mathcal{M}_2^{(k)} \supseteq \mathcal{M}_3^{(k)} \supseteq \ldots \supseteq \mathcal{M}_k^{(k)} \supseteq \mathcal{M}_{k+1}^{(k)} = \mathcal{U}^{(k)}$$

Consequently, there are $k$ different $k$-ary parts of clones of the interval $[\mathcal{U}, \emptyset]$ for each $k$.

In general, if $\mathcal{C}$ is a clone, then

$$\text{Pol}(\mathcal{C}^{(1)}) \supseteq \text{Pol}(\mathcal{C}^{(2)}) \supseteq \ldots \supseteq \text{Pol}(\mathcal{C}^{(n)}) \supseteq \ldots$$

Moreover,

$$\text{Pol}(\mathcal{C}^{(n)})^{(n)} = \mathcal{C}^{(n)} \quad \text{and} \quad \bigcap_{n \geq 1} \text{Pol}(\mathcal{C}^{(n)}) = \mathcal{C}.$$
3.3. The $m^n_k$ in the chain. As an example, we will show where the clones generated by the $m^n_k$ (as in Definition 27) and $T_1$ can be found in the chain.

**Notation 45.** For $1 \leq k \leq n$ we set $\mathcal{M}^k_n = \langle m^n_k \rangle_{T_1}$.

Note that if $k = 1$, then $\mathcal{M}^k_n = \mathcal{U}$, and if $k > \frac{n+1}{2}$, then $\mathcal{M}^k_n = \mathcal{O}$. Observe also that $\mathcal{M}^n_n = \mathcal{M}^2_n$ for all $n \geq 2$.

**Notation 46.** For a positive rational number $q$ we write
\[ [q] = \max\{n \in \mathbb{N} : n \leq q \} \]
and
\[ \lfloor q \rfloor = \min\{n \in \mathbb{N} : q \leq n \} \]
The remainder of the division $\frac{n}{k}$ we denote by the symbol $R(\frac{n}{k})$.

**Lemma 47.** Let $2 \leq k \leq \frac{n+1}{2}$ and let $t \in \mathcal{M}^k_n$ not almost unary. Then all $t$-wild subsets of $N_t$ have size at least $n-k-1$.

**Proof.** Our proof will be by induction over terms. If $t = m^n_k$, then all $t$-wild subsets of $N$ have at least $n-k+1$ elements in accordance with our assertion. For the induction step, assume $t = f(t_1, t_2)$, where $f \in T_1$, say $f(x_1, x_2) \leq \gamma(x_1)$ for some $\gamma \in \mathcal{O}(1)$. Then $t$ inherits the asserted property from $t_1$. Finally we consider the case where $t = m^n_k(t_1, \ldots, t_n)$. Suppose towards contradiction there exists $A \subseteq N_t$ t-wild with $|A| < \frac{n}{k-1} - 1$. There have to be at least $n-k+1$ terms $t_j$ for which $A$ is $t_j$-wild so that $A$ can be $t$-wild. By induction hypothesis, these $n-k+1$ terms are almost unary and bounded by a unary function of a variable with index in $A$. From the bound on the size of $A$ we conclude that there must be an index in $A$ so that at least
\[ \left\lfloor \frac{n-k+1}{|A|} \right\rfloor > \left\lfloor \frac{n-k+1}{\frac{n}{k-1} - 1} \right\rfloor = k-1 \]
of the terms $t_j$ are bounded by an unary function of the same variable. But if $k$ of the $t_j$ have the same one-element strong set, then $t$ is bounded by a unary function of this variable as well in contradiction to the assumption that $t$ is not almost unary. \hfill \Box

**Corollary 48.** Let $2 \leq k \leq \frac{n+1}{2}$. Then $\mathcal{M}_{\lfloor \frac{n}{k} \rfloor - 1} \nsubseteq \mathcal{M}^k_n$.

**Proof.** With the preceding lemma it is enough to observe that $m^n_{\frac{n}{k}} \in \mathcal{M}_{\lfloor \frac{n}{k} \rfloor - 1}$ has a wild set of size $\left\lfloor \frac{n}{k-1} \right\rfloor - 2$. \hfill \Box

So we identify now the $\mathcal{M}_j$ which $\mathcal{M}^j_n$ is equal to.

**Lemma 49.** Let $2 \leq k \leq n$. Then $\mathcal{M}_{\lfloor \frac{n}{k} \rfloor} \subseteq \mathcal{M}^k_n$.  

Proof. It suffices to show that \( m^n \) generates \( m^k \). But this is easy:
\[
m^k \left( x_1, \ldots, x_1, x_2, \ldots, x_2, \ldots, x_{\lceil \frac{n}{k-1} \rceil}, \ldots, x_{\lceil \frac{n}{k-1} \rceil} \right),
\]
where \( x_j \) occurs \( k-1 \) times if \( 1 \leq j \leq \lfloor \frac{n}{k-1} \rfloor \) and \( R(\frac{n}{k-1}) < k-1 \) times if \( j = \lfloor \frac{n}{k-1} \rfloor + 1 \). For if we evaluate the function for a \( \lceil \frac{n}{k-1} \rceil \)-tuple with \( x_j \leq \ldots \leq x_{j+\frac{n}{k-1}-1} \), then \( x_j \) occurs at most \( k-1 \) times in the tuple, but \( x_j \) together with \( x_{j+1} \) occur more than \( k \) times; thus, the \( k \)-th smallest element in the tuple is \( x_{j+1} \) and \( m \) returns \( x_{j+1} \). □

Theorem 50. \( \mathcal{M}^k_n = \mathcal{M}_{\frac{n}{k-1}} \) for all \( 2 \leq k \leq n \).

Proof. By Theorem 41, \( \mathcal{M}^k_n \) has to be somewhere in the chain \( (\mathcal{M}_n)_{n \geq 2} \). Because of Corollary 48 and Lemma 49 the assertion follows. □

3.4. Further on the chain. We conclude by giving one simple guideline for where to search the clone \( \langle f \rangle \) in the chain for arbitrary \( f \in \mathcal{O} \).

Lemma 51. Let \( 2 \leq k \leq n \) and let \( f \in \mathcal{O}^{(n)} \) be a not almost unary function which has a \( k \)-element \( f \)-wild subset of \( N \). Then \( \mathcal{M}_{k+1} \subseteq \langle f \rangle_{T_1} \).

Proof. We can assume that \( \{1, \ldots, k\} \) and all \( A \subseteq N \) with \( |A| = n-1 \) are \( f \)-insane and that \( f \) is monotone. Define
\[
g(x_1, \ldots, x_{k+1}) = f(x_1, \ldots, x_k, x_{k+1}, \ldots, x_{k+1}) \in \langle f \rangle_{T_1}.
\]
Let \( A \subseteq \{1, \ldots, k+1\} \) with \( |A| = k \) be given. If \( A = \{1, \ldots, k\} \) then \( A \) is \( f \)-wild and so it is \( g \)-wild. Otherwise \( A \) contains \( k+1 \) and so it affects \( n-1 \) components in the definition of \( g \). Therefore \( A \) is \( g \)-wild by Lemma 49. Hence, \( m^{k+1} \leq \mathcal{M}_{k+1} \subseteq \langle g \rangle_{T_1} \subseteq \langle f \rangle_{T_1} \). □

Remark 52. Certainly it is not true that if the smallest wild set of a function \( f \in \mathcal{O} \) has \( k \) elements, then \( \mathcal{M}_{k+1} = \langle f \rangle_{T_1} \). The \( m^n \) are an example.

Corollary 53. Let \( f \in Pol(T_1) \) not almost unary and such that there exists a \( 2 \)-element \( f \)-wild subset of \( N \). Then \( \langle f \rangle_{T_1} = Pol(T_1) \).

3.5. A nice picture. If \( X \) is countably infinite or weakly compact, we can draw the situation we ran into like this.
\[
\text{Pol}(T_1) = \langle T_1 \rangle, \quad \text{Pol}(T_2) = \langle T_2 \rangle
\]

\[
\mathcal{O} = \mathcal{M}_2
\]

\[
\mathcal{O}(1)
\]

\[
\mathcal{J} = \{\langle T_1 \rangle, \ldots, \mathcal{M}_3, \mathcal{M}_2\}
\]
