Abstract

Coupled quantum harmonic oscillators, studied by many authors using many different techniques over the decades, are frequently used toy models to study open quantum systems. In this paper, we explicitly study the simplest oscillator model—a pair of initially decoupled quantum harmonic oscillators interacting with a spring-like coupling, where the bath oscillator is initially in a thermal-like state. In particular, we treat the completely positive and trace-preserving map on the system as a quantum channel and study the truncation of the channel by truncating its Kraus set and its output dimension. We thereby derive the truncated transition amplitudes of the corresponding truncated channel. Finally, we give a computable approximation for these truncated transition amplitudes with explicit error bounds and perform a case study of the oscillators in the off-resonant and weakly coupled regime numerically. We demonstrate explicitly that the substantial leakage error can be mitigated via quantum error correction.

1. Introduction

One of the canonical physical models in quantum physics is that of quantum oscillators coupled with harmonic baths. The dynamics of such models and their variations has been extensively studied, using various techniques [1–11]. These techniques include Markovian master equations [12], quantum stochastic processes and quantum Langevin equations [13–15, 1, 16, 17], Kossakowski–Lindblad equations [18, 19], methods in density-functional theory [20], the standard techniques of perturbation theory, among many others [21, 22].

Quantum channels [23] can be used to quantify the dynamics of a quantum system and can be described by truncated transition amplitudes. In this paper, we approximate the truncated
transition amplitudes of a given channel, where the truncation is performed with respect to the quantum channel’s set of Kraus operators and its dimensions. A truncated quantum channel is a trace-decreasing quantum operation and quantifies the partial dynamics acting on the system. Knowledge of the truncated quantum channel has utility—lower bounds on the performance of quantum error correction codes with its knowledge [24–32].

In this paper, we work toward quantifying the approximate dynamics of a pair of initially decoupled quantum harmonic oscillators interacting with a spring-like coupling, where the bath oscillator is initially in a thermal-like state. We work with a truncated subset of the model’s Kraus operators, and thereby approximate its truncated transition amplitudes. We note that the Kraus operators of oscillator-bath models have also been approximated by various authors [6, 33, 34]. Recently, Holevo also gave a formal exact expression for the Choi–Jamiolkowski (CJ) operator for Gaussian channels [35], which describes the dynamics of coupled oscillators. Our contributions in this paper are the explicit upper bounds on the approximation error of the truncated transition amplitudes of two quantum harmonic oscillators coupled via a spring-like interaction, where the approximation is an explicit summation of a finite number of computable terms, and dependent on the size of the input and output dimensions of the truncated channel. Our results can be used to explicitly study this toy model with rigorous error bounds. In particular, we numerically demonstrate and provide lower bounds for the leakage error and show how this leakage error is mitigated via quantum error correction.

The organization of this paper is as follows. In section 2, we introduce the preliminary material needed for this paper. In particular, we review \( L^2(\mathbb{R}) \) Hilbert space, quantum states, quantum channels, Hermite functions and the linear canonical transformations for the quantum harmonic oscillator. In section 3, we give a treatment of the truncated dynamics of two quantum harmonic oscillators interacting with a spring-like coupling and give explicit bounds on the error term induced by approximating the truncated transition amplitudes with a finite sum in theorem 3.1. In section 4, we give bounds on Hermite functions that are needed for the proof of theorem 3.1. Finally, we apply our results explicitly in section 5 in the case where the oscillators are off-resonant and weakly coupled.

2. Preliminaries

In this section, we review the theory of \( L^2(\mathbb{R}) \) Hilbert spaces, quantum states and various representations of quantum channels, Hermite polynomials and functions and coupled harmonic oscillators.

2.1. The \( L^2(\mathbb{R}) \) Hilbert spaces

We refer the reader to [36, 37] for an introduction to separable Hilbert spaces. In this paper, all Hilbert spaces are complex and separable, have countable bases and are typically isomorphic to the set of square integrable functions \( L^2(\mathbb{R}) \) which necessarily have infinite dimensions. For Hilbert spaces \( \mathcal{H} \) and \( \mathcal{K} \), let \( L(\mathcal{H}, \mathcal{K}) \) denote the set of linear operators mapping \( \mathcal{H} \) to \( \mathcal{K} \) and \( L(\mathcal{H}) := L(\mathcal{H}, \mathcal{H}) \). Let \( \mathcal{B}(\mathcal{H}, \mathcal{K}) \) denote the set of bounded operators in \( L(\mathcal{H}, \mathcal{K}) \).

We use Dirac’s ‘ket’ \( |\psi_{\mathcal{H}}\rangle \) to denote a function \( \psi \) in the Hilbert space \( \mathcal{H} \). For Hilbert space \( \mathcal{H} \), let \( \{ |j\rangle_{\mathcal{H}} \} \in \mathbb{N} \) denote its generic orthonormal basis. We also use \( |\psi_{\mathcal{H}}, \varphi_{\mathcal{K}}\rangle \) and \( |\psi_{\mathcal{H}}\rangle |\varphi_{\mathcal{K}}\rangle \) to denote \( |\psi_{\mathcal{H}}\rangle \otimes |\varphi_{\mathcal{K}}\rangle \). We denote the inner product of Hilbert space \( \mathcal{H} \) using the Dirac notation as \( \langle \cdot | \cdot \rangle_{\mathcal{H}} \) which is a sesquilinear form. For functions \( \psi, \varphi \in \mathcal{H} = L^2(\mathbb{R}) \), their inner product in the position basis is \( \langle \psi | \varphi \rangle_{\mathcal{H}} := \int_\mathbb{R} \psi(x)^* \varphi(x) \, dx \). The physicist’s position and momentum operators \( \hat{x}_{\mathcal{H}} \) and \( \hat{p}_{\mathcal{H}} \) are sesquilinear forms that map the tuple \( (|\psi_{\mathcal{H}}\rangle, |\varphi_{\mathcal{H}}\rangle) \) to
trace-1 operators in $\Phi_1(\rho)$ of quantum states on Hilbert space $K$ where $\int J. Phys. A: Math. Theor. 2013$ 205301 Y Ouyang and W H Ng

2.2. Quantum states and channels

We refer the reader to [23] for an introduction to quantum states and channels. Define the set of quantum states on Hilbert space $\mathcal{H}$ to be $\mathcal{D}(\mathcal{H})$, the set of all positive semi-definite and trace-1 operators in $\mathcal{B}(\mathcal{H})$. When $\rho \in \mathcal{D}(\mathcal{H} \otimes K)$, we denote the partial trace of $\rho$ on Hilbert space $\mathcal{H}$ as $\text{tr}_\mathcal{H}(\rho) := (j_{\mathcal{H}}| \rho | j_{\mathcal{H}})$. A quantum channel $\Phi : \mathcal{B}(\mathcal{H}) \rightarrow \mathcal{B}(K)$ is a completely positive and trace-preserving linear map and its non-unique Kraus representation is [38–40]

$$\Phi(\rho) = \sum_{K \in \mathcal{R}} K \rho K^\dagger, \quad \sum_{K \in \mathcal{R}} K^\dagger K = \mathbb{1}_{\mathcal{H}},$$

where $\mathcal{R} \subset \mathcal{B}(K, \mathcal{H})$ is called the Kraus set of $\Phi$. We denote the basis-dependent matrix elements of the Kraus operators by $K_{j,j'}$ so that for all $K \in \mathcal{R}$,

$$K = \sum_{j,j'} K_{j,j'} |j_{\mathcal{H}}⟩⟨j'_{\mathcal{H}}|. $$

We define the transition amplitudes of $\Phi$ with respect to the Kraus set $\mathcal{R}$ to be

$$T^{(a,b)\rightarrow(a',b')}_{\mathcal{R}} := \sum_{K \in \mathcal{R}} K_{b,a} K^*_{a',a'},$$

a sum of the product of two Kraus operators over the entire Kraus set. Now let $\rho \in \mathcal{D}(\mathcal{H})$ and $\Phi(\rho) \in \mathcal{D}(K)$ have the decompositions

$$\rho = \sum_{a,b} \rho_{a,b}|b_{\mathcal{H}}⟩⟨a_{\mathcal{H}}|, \quad \Phi(\rho) = \sum_{a',b'} \rho'_{a',b'}|b'_{\mathcal{H}}⟩⟨a'_{\mathcal{H}}|$$

so that in the Kraus representation,

$$|b'_{\mathcal{K}}⟩⟨a'_{\mathcal{K}}| = |b'_{\mathcal{K}}⟩ \sum_{K \in \mathcal{R}} K \rho K^\dagger |a'_{\mathcal{K}}⟩ = |b'_{\mathcal{K}}⟩ \sum_{K \in \mathcal{R}} \sum_{j,j'} K_{j,j'} |j_{\mathcal{H}}⟩ \sum_{a,b} \rho_{a,b}|b_{\mathcal{H}}⟩⟨a_{\mathcal{H}}| \sum_{k,k'} K^*_{k,k'} |k_{\mathcal{H}}⟩ ⟨k_{\mathcal{H}}|a'_{\mathcal{K}}⟩ = \sum_{K \in \mathcal{R}} \sum_{j,j'} \sum_{a,b} K_{j,j'} K^*_{k,k'} \rho_{a,b} ⟨j_{\mathcal{H}}|b_{\mathcal{H}}⟩ ⟨k_{\mathcal{H}}|a_{\mathcal{H}}⟩ ⟨k'_{\mathcal{K}}|a'_{\mathcal{K}}⟩ = \sum_{a,b \in \mathbb{N}} \left( \sum_{K \in \mathcal{R}} K_{b,a} K^*_{a,a'} \right) \rho_{a,b} = \sum_{a,b \in \mathbb{N}} T^{(a,b)\rightarrow(a',b')}_{\Phi,\mathcal{R}} \rho_{a,b}. \quad (2)$$

Hence, $T^{(a,b)\rightarrow(a',b')}_{\Phi,\mathcal{R}}$ quantifies the transition amplitudes of $⟨b_{\mathcal{H}}|\rho|a_{\mathcal{H}}⟩$ to $⟨b'_{\mathcal{H}}|\Phi(\rho)|a'_{\mathcal{H}}⟩$. For the purpose of quantum information processing, it may not be necessary to work with the full Kraus set $\mathcal{R}$. In this paper, we instead restrict our attention to the truncated Kraus set $\Omega$, which is some appropriately chosen subset of the full Kraus set. This truncation procedure approximates the channel well if the truncated Kraus set comprises the ‘typical’ Kraus effects. For the purpose of quantum error correction, partial knowledge of the channel is already of great utility and recovery channels can be constructed based on this partial information to give lower bounds on the entanglement fidelity of specifically chosen quantum codes. Hence in this paper, the truncated transition amplitudes $T^{(a,b)\rightarrow(a',b')}_{\Omega}$ play a central role in quantifying the truncated dynamics of the channel $\Phi$. 

3
2.3. Hermite polynomials and functions

For \( n \in \mathbb{N} \), define the Hermite polynomials \( H_n(x) \) and the Hermite functions \( \psi_n(x) \) to be

\[
H_n(x) := (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2}, \quad \psi_n(x) := \frac{e^{-\frac{1}{2}x^2} H_n(x)}{\sqrt{2^n n! \sqrt{\pi}}}. \tag{3}
\]

For example, \( H_0(x) = 1 \) and \( H_1(x) = 2x \). The reader can refer to [41] for the properties of the Hermite polynomials and functions. For \( c > 0 \), also define the rescaled Hermite function to be

\[
\psi_{n,c}(x) = \langle \tilde{x}_T | \psi_{n,c,T} \rangle := \sqrt{c} \psi_n(cx). \tag{4}
\]

As stated by Watson [42], Mehler’s formula applies in the case when \( |z| < 1 \) and \( z \) is real, i.e.

\[
\sum_{n=0}^{\infty} e^{\sqrt{\pi n}(x-y)} \psi_n(x) \psi_n(y) = \frac{1}{\sqrt{\pi \left(1 - z^2\right)}} \exp \left[ \frac{4xyz - (x^2 + y^2)(1 + z^2)}{2(1 - z^2)} \right]. \tag{5}
\]

Mehler’s formula also holds for all complex numbers \( |z| < 1 \), with the series converging uniformly and absolutely [43, theorem 23.1]).

2.4. A pair of harmonic oscillators and their linear canonical transformations

2.4.1. The classical model. We refer the reader to [44] for an introduction to the quantum harmonic oscillator. Define the classical Hamiltonian of a classical harmonic oscillator with mass \( m \), resonant frequency \( \omega \), position coordinate \( x \) and momentum coordinate \( p \) to be

\[
H_{m,\omega,x,p} := \frac{p^2}{2m} + \frac{1}{2} m\omega^2 x^2. \tag{6}
\]

The model we study has the classical Hamiltonian

\[
H = H_{m_1,\omega_1,x_1,p_1} + H_{m_2,\omega_2,x_2,p_2} + H_{\text{int}}, \tag{7}
\]

where \( H_{\text{int}} := \frac{1}{2} k(x-y)^2 \) is the classical Hamiltonian representing the spring-like interaction between the oscillators where \( k \geq 0 \). The spring-like interaction \( H_{\text{int}} \) introduces quadratic terms \( \frac{kx^2}{2} \) and \( \frac{kx^2}{2} \) into \( H \), effectively renormalizing the oscillator frequencies from \( \omega_{x, \omega} \) and \( \omega_{y, \omega} \) to \( \omega_x := \sqrt{\omega_{x, \omega}^2 + \frac{k}{m_1}} \) and \( \omega_y := \sqrt{\omega_{y, \omega}^2 + \frac{k}{m_2}} \), respectively. Hence, when \( H_{\text{int}} := -kxy \),

\[
H = H_{m_1,\omega_1,x_1,p_1} + H_{m_2,\omega_2,x_2,p_2} + H_{\text{int}}. \tag{7}
\]

In an experimental setup, it may be impossible to turn off the interaction between the two oscillators. Then, the physically measured oscillator frequencies correspond to the renormalized frequencies. Therefore, we work with the renormalized representation of the model Hamiltonian given by (7).

2.4.2. The quantized model. Define the Hamiltonian of a quantum harmonic oscillator with associated Hilbert space \( \mathcal{H} \), mass \( M > 0 \), resonant frequency \( \omega > 0 \), position operator \( \hat{x}_T \) and momentum operator \( \hat{p}_T \) to be

\[
H_{M,\omega,\hat{x}_T,\hat{p}_T} := \frac{\hat{p}_T^2}{2M} + \frac{1}{2} M\omega^2 \hat{x}_T^2. \tag{8}
\]

The set of rescaled Hermite functions \( \{ |\psi_n,\sqrt{\pi} \rangle \}_n \in \mathbb{N} \) is the set of energy eigenfunctions of the Hamiltonian \( H_{(M,\omega,\hat{x}_T,\hat{p}_T)} \). Let the Hilbert space of the first and second oscillators be
\(X\) and \(Y\), respectively, both isomorphic to \(L^2(\mathbb{R})\). Define \(\hat{x} := \hat{x}_X \otimes 1_Y, \hat{y} := 1_X \otimes \hat{y}_Y, \hat{p}_x := \hat{p}_X \otimes 1_Y\) and \(\hat{p}_y := 1_X \otimes \hat{p}_Y\). Then, the quantized model Hamiltonian (7) is

\[
H = H_{m,o_0;\hat{x}_X,\hat{x}_Y} \otimes 1_Y + 1_X \otimes X H_{m_o,o_Y;\hat{y}_{X},\hat{p}_Y} + H_{\text{int}}
\]

where \(H_{\text{int}} := -k \hat{x} \hat{y}\) is the quantized interaction.

The coupled quantum harmonic oscillators can be decoupled by a linear canonical transformation of the oscillator positions and momenta [45]. Define the rotation matrix, the rotation angle and the rescaled mass by

\[
R := \begin{pmatrix}
\cos \theta & \sin \theta \\
-\sin \theta & \cos \theta
\end{pmatrix}, \quad \theta := \frac{1}{2} \tan^{-1} \left( \frac{2k/m}{\omega_x^2 - \omega_y^2} \right), \quad m := \sqrt{m_x m_y},
\]

respectively. The use of straightforward trigonometry then gives

\[
cos \theta = \frac{1}{\sqrt{2}} \left( 1 + \frac{1}{\sqrt{1 + \frac{4k^2/m^2}{(\omega_x^2 - \omega_y^2)}}} \right)^{1/2}, \quad \sin \theta = \frac{1}{\sqrt{2}} \left( 1 - \frac{1}{\sqrt{1 + \frac{4k^2/m^2}{(\omega_x^2 - \omega_y^2)}}} \right)^{1/2},
\]

where

\[
\frac{4k^2/m^2}{(\omega_x^2 - \omega_y^2)} = 4 \left( \frac{m_x m_y}{k} \left( \omega_{x,0} - \omega_{y,0} \right) + m_x - m_y \right) \sqrt{m_x m_y}.
\]

Note that the rotation angle quantifies the strength of the coupling in the sense that \(\cos \theta \approx 1\) and \(\sin \theta \approx 0\) when the coupling constant \(k\) is small and the oscillators are off-resonant. Define the normalization parameter \(\mu := \sqrt{\frac{m_x m_y}{m}}\). Then, we choose the transformed position and momenta operators to be given by

\[
(\hat{u}, \hat{v}) := R(\mu^{-1} \hat{x}, \mu \hat{y}), \quad (\hat{p}_u, \hat{p}_v) := R(\mu \hat{p}_x, \mu^{-1} \hat{p}_y),
\]

where \((x_1, x_2, \ldots)\) denotes a column vector. The quantized Hamiltonian is

\[
H = H_{m_o;\hat{u},\hat{p}_u} + H_{m_o;\hat{v},\hat{p}_v},
\]

where

\[
\omega_u = \sqrt{\left( \frac{\omega_x}{\omega_u} \right)^2 \cdot \frac{\cos^2 \theta}{\sin^2 \theta} - \frac{k}{m} \sin(2\theta)}, \quad \omega_v = \sqrt{\left( \frac{\omega_y}{\omega_v} \right)^2 \cdot \frac{\sin^2 \theta}{\cos^2 \theta} + \frac{k}{m} \sin(2\theta)}.
\]

Note that the frequencies \(\omega_u\) and \(\omega_v\) are real as long as the original oscillator frequencies \(\omega_{x,0}\) and \(\omega_{y,0}\) before renormalization are also real because the renormalized frequencies \(\omega_u\) and \(\omega_v\) increase as the coupling strength \(k\) increases.

The linear canonical transformation that decouples the pair of harmonic oscillators is not unique. We chose the transformation that gives the same mass \(m\) for the decoupled oscillators, so that the only parameters different between them are the frequencies \(\omega_u\) and \(\omega_v\). Since the transformation we have performed is canonical, \([\hat{u}, \hat{v}] = [\hat{p}_u, \hat{p}_v] = [\hat{u}, \hat{p}_v] = [\hat{v}, \hat{p}_u] = 0\), \([\hat{u}, \hat{p}_u] = i\hbar\) and \([\hat{v}, \hat{p}_v] = i\hbar\). Hence, there exist Hilbert spaces \(U, V\) isomorphic to \(L^2(\mathbb{R})\) such that \(X \otimes Y = U \otimes V, \hat{u} = \hat{u}_U \otimes 1_V, \hat{v} = 1_U \otimes \hat{v}_Y, \hat{p}_u = \hat{p}_U \otimes 1_V\) and \(\hat{p}_v = 1_U \otimes \hat{p}_Y\).

Let \(c_u := \sqrt{\frac{m}{m_u}}\) and \(c_v := \sqrt{\frac{m}{m_v}}\), \(c_x := \sqrt{\frac{m_u}{m}}\) and \(c_y := \sqrt{\frac{m_v}{m}}\). Then, the set of eigenstates of the uncoupled Hamiltonians \(H_{m_o;\hat{u},\hat{p}_u} + H_{m_o;\hat{v},\hat{p}_v}\) and the full Hamiltonian \(H\) are \(\{ |\psi_{\varphi, c_u, U, \psi_{x, c_x, U}}\rangle \}_{x \in \mathbb{N}}\) and \(\{ |\psi_{\varphi, c_v, V, \psi_{y, c_y, V}}\rangle \}_{y \in \mathbb{N}}\), respectively.

5
3. Truncated dynamics of the interacting system

This section highlights the main results of our paper. We provide a computable approximation to our physical model’s truncated channel with corresponding error bounds that are simple to describe.

3.1. The general model

The Hilbert space of our model has the general form $H = \mathcal{X} \otimes \mathcal{Y}$, where $\mathcal{X}$ and $\mathcal{Y}$ are separable Hilbert spaces of the system and the environment, respectively. Our model’s Hamiltonian is

$H = H_s \otimes \mathbb{1}_Y + \mathbb{1}_X \otimes H_e + H_{int}$

where $H_s$, $H_e$, and $H_{int}$ are (typically unbounded) Hermitian operators in the sets $L(H)$, $L(X)$, $L(Y)$ and $L(\mathcal{H})$, respectively. The Hamiltonians $H_s$ and $H_e$ describe the bare dynamics on $\mathcal{X}$ and $\mathcal{Y}$, respectively, and $H_{int}$ describes the system–bath interaction.

Let the initial state of the entire model be $\rho_{in} := \rho_0 \otimes \sigma_y$, where $\rho_0 \in \mathbb{D}(\mathcal{X})$ and the bath state is $\sigma_y = \sum_{n \in \mathbb{N}} p_n |\ell_y\rangle \langle \ell_y| \in \mathbb{D}(\mathcal{Y})$. Let $\Phi_t$ be the unitary operator $U_t \in \mathbb{B}(\mathcal{H})$. Then, the time-evolved state of system $\mathcal{X}$ at time $t$ is

$\rho_t := \Phi_t(\rho_0) = \text{tr}_Y U_t \rho_{in} U_t^\dagger$

$= \sum_{j, j', \ell, \ell' \in \mathbb{N}} \langle j_y | U_j | j'_y \rangle \langle j'_y | \rho_0 \otimes p_\ell |\ell_y\rangle \langle \ell_y | j'_y \rangle \langle j'_y | U_j^\dagger | j_y \rangle$

$= \sum_{\ell, \ell' \in \mathbb{N}} \langle \ell_y | U_\ell | \ell_y \rangle p_\ell \rho_0 (|\ell_y\rangle \langle \ell_y|)$

(14)

Using (1), a feasible Kraus set and transition amplitudes for $\Phi_t$ are

$K_{\ell} := \{ \sqrt{p_\ell} |\ell_y\rangle \langle \ell_y| : \ell, \ell' \in \mathbb{N} \}$

(15)

$T_{K_{\ell}}(a \mapsto a') = \sum_{\ell, \ell' \in \mathbb{N}} p_\ell b_\ell \langle \ell_y | U_\ell | a \rangle \langle a | \ell_y \rangle (|a\rangle \langle a|)_{\ell, \ell'}$

(16)

The transition amplitudes (16) of the full quantum channel may be impossible to evaluate because of the infinite summation that is required. In view of this, we can instead evaluate the truncated transition amplitudes by truncating the infinite summation. These truncated transition amplitudes are the transition amplitudes of the truncated quantum channel.

3.2. Coupled harmonic oscillators

The approximate dynamics of coupled harmonic oscillators is still actively studied [46, 47]. In our paper, we use the model as described in section 2.4.2. Let $z_a := e^{-i \omega_a t}$ and $z_b := e^{-i \omega_b t}$. For $j \in \mathbb{N}$, define $|j_\ell \rangle := \ket{\psi_{j, \ell, a}, \chi_{\ell, b}}$, $|j_\ell \rangle := \ket{\psi_{j, \ell, a}, \chi_{\ell, b}}$, $|j_\ell \rangle := \ket{\psi_{j, \ell, a}, \chi_{\ell, b}}$ and $|j_\ell \rangle := \ket{\psi_{j, \ell, a}, \chi_{\ell, b}}$. Then, the unitary operator $U_t$ has the spectral decomposition

$U_t = \sum_{\kappa, \ell \in \mathbb{N}} \sqrt{z_{a, \ell} z_{b, \ell}} |\ell_\kappa, \chi_\ell \rangle \langle \kappa_\ell, \chi_\ell |$

(17)

Let $r = \exp(-\frac{\hbar \omega}{k_B T}) \in [0, 1)$, where $k_B$ is the Boltzmann constant and $0 \leq T < \infty$ is the effective temperature of the bath. The state of the bath with a Boltzmannian distribution is

$\sigma_y = \sum_{\ell \in \mathbb{N}} p_\ell r^\ell (1 - r) |\ell \rangle \langle \ell|$

(18)

Thus, $p_\ell = r^\ell (1 - r)$ in equations (15) and (16).
3.2.1. Kraus operators and transition amplitudes. Using (15), the matrix elements of our Kraus operator \( K \in \mathcal{K} \) indexed by \( \ell, \ell' \in \mathbb{N} \) are

\[
\langle j| K | j' \rangle = \sqrt{p_{\ell}} \langle j'| \U_{\ell} | j \rangle = \sqrt{p_{\ell}'} \langle j'| \U_{\ell'} | j \rangle = \sqrt{p_{\ell}''} \langle j'| \U_{\ell''} | j \rangle.
\]

The goal is now to find an expression for the truncated transition amplitudes for small values of \( a, b, a' \) and \( b' \). We first give an expression for the transition amplitude with respect to the full Kraus set \( \mathcal{K} \), which is

\[
T_{a,b}^{(a',b')} = \sum_{\ell, \ell' \in \mathbb{N}} r^\ell (1 - r) \langle \ell' | b | \ell \rangle \langle \ell | a' | \ell' \rangle \langle \ell' | a | \ell \rangle.
\]

The matrix elements in the expression above can be simplified by expressing them in the \( x \) and \( y \) coordinates of the original oscillators. In particular, the expression above becomes an integral of the product of rescaled Hermite functions. To simplify the notation, let \( u_{x,y} := \frac{c_u}{\sqrt{\ell_u}} \cos \theta + \frac{c_v}{\sqrt{\ell_v}} \sin \theta \) and \( v_{x,y} := \frac{c_u}{\sqrt{\ell_u}} (-\frac{1}{\ell_u} \sin \theta + \frac{c_v}{\ell_v} \cos \theta \) denote the coordinates of the decoupled oscillators in the basis of the original oscillators. By making appropriate substitutions, we have that

\[
u_{x,y} = \frac{m_u \omega_u}{m_v \omega_v} \cos \theta + \frac{m_v \omega_v}{m_u \omega_u} \sin \theta \]

\[
u_{x,y} = - \frac{m_u \omega_u}{m_v \omega_v} \cos \theta + \frac{m_v \omega_v}{m_u \omega_u} \sin \theta. \tag{21}
\]

The summation indices in the transition amplitude corresponding to the full Kraus set \( \mathcal{K} \) in (20) are \( \ell \) and \( \ell' \), respectively. In this paper, we choose our truncated Kraus set to be \( \Omega_{\ell_u, \ell_v} \), where only the summation over \( \ell' \) is truncated.

By applying Mehler’s formula (5) on the variable \( \ell \), the expression for the truncated transition amplitude is

\[
T_{\ell_u, \ell_v}^{(a',b')} = \sum_{\ell \in \ell_u} \sum_{\kappa, \chi, \chi' \in \ell'} \sum_{\kappa', \chi'} \sum_{\chi } \sum_{\kappa} \sum_{\chi' } f[a, b, a', b'; \ell, \kappa, \chi, \chi', \chi', \chi'] \frac{\omega_u \omega_v}{\omega_u \omega_v} \sqrt{\frac{1 - r}{\pi (1 + r)}}.
\]

where the path-dependent and time-independent transition amplitudes

\[
f[a, b, a', b'; \ell, \kappa, \chi, \chi', \chi, \chi'] := \int_{x,y \in \mathbb{R}^2} \text{d}x \text{d}y \exp \left[ - \frac{1 + r^2}{2(1 + r^2)} \left( y_3^2 - 4ry_3y_4 + y_4^2 \right) \right]
\]

\[
\times (\psi_{\ell} (x_1) \psi_{\ell} (x_2) \psi_{\ell} (x_3) \psi_{\ell} (x_4))(\psi_{\ell'} (y_1) \psi_{\ell'} (y_2))
\]

\[
\times \psi_{\ell'} (u_{x,y_1}) \psi_{\ell'} (u_{x,y_2}) \psi_{\ell'} (u_{x,y_3}) \psi_{\ell'} (u_{x,y_4})
\]

\[
\times \psi_{\ell} (v_{y_1}, y_1) \psi_{\ell} (v_{y_2}, y_2) \psi_{\ell} (v_{y_3}, y_3) \psi_{\ell} (v_{y_4}, y_4), \tag{22}
\]

where \( x = (x_1, x_2, x_3, x_4) \) and \( y = (y_1, y_2, y_3, y_4) \) are the rescaled position coordinates of the system and environment oscillators, respectively. The integral \( f \) can be more easily evaluated if we express it as a product of three integrals in the sense that

\[
f[a, b, a', b'; \ell, \kappa, \chi, \chi', \chi, \chi'] = J_{\ell, \kappa, \chi, \chi'} J_{b, a, \kappa, \chi, \chi', \chi}, \tag{24}
\]
where the integrals are

\[ I_{a,c',x',y'} := \int_{\mathbb{R}^2} \Theta_{x,y}(a'; c') \psi_{c'}(u_{x,y}) \psi_{y'}(v_{x,y}) \, dx \, dy \]  

(25)

\[ J_{b,a,x,y,z}(b, a; r) \psi_{k}(u_{w,z}) \psi_{x'}(v_{w,z}) \psi_{y'}(v_{w,z}) \, dw \, dx \, dz, \]  

and the kernels are

\[ \Theta_{x,y}(i; j) := \psi_i(x) \psi_j(y) \]  

(27)

\[ \Theta_{w,x,y,z}(i; j; r) := \psi_i(w) \psi_j(y) \exp \left[ -\frac{1 + r^2}{2(1 - r^2)} (y^2 - \frac{4r}{1 + r^2}yz + z^2) \right]. \]  

(28)

Now our truncated transition amplitude is still a sum over an infinite number of integrals, and hence we intend to approximate it by the finite sum

\[ A_{L,N,t}^{(a,b) \rightarrow (a',b')} = \sum_{L  \leq L} \sum_{k' \leq N} \int_{\mathbb{R}^2} \Theta_{x,y}(a'; c') \psi_{c'}(u_{x,y}) \psi_{y'}(v_{x,y}) \frac{\omega_{a,b}}{\omega_{a',b'}} \sqrt{\frac{1 - r}{\pi(1 + r)}} \]  

(29)

for some positive integer \( N \). In theorem 3.1, we prove that the absolute value of the error term by approximating the truncated transition amplitude (22) with (29) vanishes as \( N \) becomes large while \( a, b, a', b' \) and \( L \) remain small. The proof of our theorem uses mainly the Cauchy–Schwarz inequality, and lemmas 4.3 and 4.4. The intuition behind our technical lemmas is an elementary consequence of the behavior of order-

|Schwarz inequality, and lemmas4.3 and 4.4. The intuition behind our technical lemmas is an

|truncated transition amplitude defined in (22) that has an approximation \( A_{L,N,t}^{(a,b) \rightarrow (a',b')} \) given by (29). Then for all integers \( 0 \leq a, b, a', b' \leq D, \)

Theorem 3.1. Let \( m_i, m_j, \omega_x, \omega_y, t > 0, k \geq 0 \) and \( 0 \leq r < 1 \) be real numbers, and \( D, L \)

and \( N \) be positive integers. Let \( C \) be a constant that depends on \( m_i, m_j, \omega_x, \omega_y \) and \( k \) (see (34)), and \( A, A, B, B \) be constants that depend on \( D \) and \( L \) (see (35)). Let \( T_{L,N,t}^{(a,b) \rightarrow (a',b')} \) be the truncated transition amplitude defined in (22) that has an approximation \( A_{L,N,t}^{(a,b) \rightarrow (a',b')} \) given by (29). Then for all integers \( 0 \leq a, b, a', b' \leq D, \)

Remark 3.2. Observe that when \( C \) is a very large number, the upper bound of the above theorem is dominated by the expression

\[ \frac{4A^2B}{81(N - \frac{1}{2})^6} \left( \frac{\omega_y \omega_a}{\omega_x \omega_b} \sqrt{\frac{1 - r}{\pi(1 + r)}} (L + 1) \right) \leq \frac{14.7103(L + 1)^{\frac{1}{2}}}{(N - \frac{1}{2})^6} \left( \frac{\omega_y \omega_a}{\omega_x \omega_b} \sqrt{\frac{1 - r}{\pi(1 + r)}} \right) \]  

as \( N \) becomes large (and \( \bar{n}_l \) is defined as \( \max_{0 \leq l \leq \ell} \| \psi_l \|_1 \)).

8
Remark 3.3. If the parity of $a + b$ differs from that of $a' + b'$, the approximate truncated amplitude is necessarily identically zero for all positive integers $L$ and $N$. This is a result of a simple parity counting argument after noting that the I-type integrals (25) and J-type integrals (26) are zero whenever the parity of the sum of their indices is odd. Hence, the parity is conserved with regard to our physical model.

Remark 3.4. The bounds of theorem 3.1 can be substantially tightened using information pertaining to the I-type integrals (25), which are substantially simpler to evaluate than the J-type integrals (26). Using bounds for the J-type integrals (37), we have that for integer $N'$ greater than $N$,

$$
|T_{(a,b)\rightarrow(a',b')} - A_{L,N,t}^{(a,b)\rightarrow(a',b')}| \leq \sum_{0 \leq \ell \leq L} \sum_{N < \kappa, \kappa' \leq N'} |I_{a,a',\ell',\ell}| I_{b,b',\kappa,\kappa'} B(k \kappa' \chi \chi')^{-5/2}
$$

$$
+ \left| T_{(a,b)\rightarrow(a',b')} - A_{L,N',t}^{(a,b)\rightarrow(a',b')} \right|, \tag{31}
$$

Figure 1. The area inside the square corresponds to the region $A_1$ (where $|\psi(ax + by)| \leq 1.74 a^{-5/4}$) and the area outside the circle corresponds to the region $A_2$ (where all Hermite functions decay exponentially).
Proof of theorem 3.1. Our goal is to obtain upper bounds on each of the integrals $I$ and $J$ defined in (25) and (26). Applying the Cauchy–Schwarz inequality on $|I_{\alpha,\ell',\kappa',\chi'}|$ gives

$$|I_{\alpha,\ell',\kappa',\chi'}| \leq \sqrt{\int_{\mathbb{R}^2} |\Theta_{\alpha,\ell'}(\alpha'; \ell')| \psi_{\alpha}(u_{\psi})^2 \, dx \, dy} \sqrt{\int_{\mathbb{R}^2} |\Theta_{\alpha,\ell'}(\alpha'; \ell')| \psi_{\chi'}(u_{\chi'})^2 \, dx \, dy}. \quad (32)$$

We similarly use the Cauchy–Schwarz inequality to obtain an upper bound of the absolute value of (26), which is

$$|J_{b,a,\kappa,\chi',\kappa',\chi}| \leq \sqrt{\int_{\mathbb{R}^2} |\Theta_{b,a,\kappa,\chi',\kappa',\chi}(b, a; r)| \psi_{\kappa}(u_{\psi})^2 \psi_{\chi'}(u_{\chi'})^2 \, dx \, dy} \times \sqrt{\int_{\mathbb{R}^2} |\Theta_{b,a,\kappa,\chi',\kappa',\chi}(b, a; r)| \psi_{\chi}(u_{\psi})^2 \psi_{\chi'}(u_{\chi'})^2 \, dx \, dy}. \quad (33)$$

For the purpose of using lemmas 4.3 and 4.4, define the constants

$$c_1 = \min \left\{ \frac{m_{\alpha,\omega}}{m_{\alpha,\omega}} \cos \theta, \frac{m_{\alpha,\omega}}{m_{\alpha,\omega}} \sin \theta \right\}, \quad c_2 = \min \left\{ \frac{m_{\alpha,\omega}}{m_{\alpha,\omega}} \sin \theta, \frac{m_{\alpha,\omega}}{m_{\alpha,\omega}} \cos \theta \right\}, \quad C = \min \{1/(4c_1^2), 1/(4c_2^2)\} \quad (34)$$

and

$$A = 1.74 \left( \max_{0 \leq j \leq D} \|\psi_j\|_1 \right) \left( \max\left\{ \Theta_{\psi_j}\right\} \right), \quad \tilde{A} = (4.74) (2 e^{-\frac{1}{2}}) \sqrt{D!D!L!L!}$$

$$B = 57.6 \left( \max_{0 \leq j \leq D} \|\psi_j\|_1 \right)^2, \quad \tilde{B} = (39.6) (2 e^{-1}) D!D!.$$

Noting that $\sin \theta$ and $\cos \theta$ are non-negative by definition (see (11)), and using the definitions of $c_1$, $c_2$ and $C$ with lemma 4.3, we have that

$$|I_{\alpha,\ell',\kappa',\chi'}| \leq A(\chi')^{-5/2} + \tilde{A} e^{-\chi C} \sqrt{A(\kappa')^{-5/2} + \tilde{A} e^{-\kappa C}} \quad (36)$$

and we have a similar upper bound of $|I_{\psi,\psi'|\chi'|\chi}|$. Using lemma 4.4, we have that

$$|J_{b,a,\kappa,\chi',\kappa',\chi}| \leq B(\kappa'\chi')^{-5/2} \tilde{B} e^{-\kappa'\chi'C} B(\kappa'\chi')^{-5/2} \tilde{B} e^{-\kappa'\chi'C}. \quad (37)$$

By expanding out the terms of the products of the upper bounds given by (36) and (37), our upper bound on the absolute value of (24)

$$|f(\alpha, b, \alpha', b'; \ell', \kappa, \kappa', \chi, \chi')| \leq W_\kappa W_\chi W_\chi$$

where

$$W_{\kappa,\kappa'} := \frac{A^2 B}{\kappa^3 (\kappa')^3} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} e^{-\kappa' C} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} e^{-\kappa C} \frac{A^2 \tilde{B}}{\kappa^{5/2} (\kappa')^{5/2}} e^{-\kappa C} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} e^{-\kappa+\kappa' C}$$

$$+ \frac{A\tilde{A} B}{\kappa^{5/2} (\kappa')^{5/2}} e^{-(\kappa+\kappa') C} + \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} e^{-(\kappa+\kappa') C} + \frac{A\tilde{A} B}{\kappa^3 (\kappa')^3} e^{-(\kappa+\kappa') C}$$

By the subadditivity of the square root function, we have that
with exponentially decaying terms and the terms:

\[
\sqrt{W_{\kappa, \kappa'}} \leq \frac{\sqrt{A^2 B}}{\kappa^{5/2} (\kappa')^{5/2}} + \frac{\sqrt{\kappa \kappa'}}{\kappa^{5/2} (\kappa')^{5/2}} e^{-x(C/2)} + \frac{\sqrt{AAB}}{\kappa^{5/2} (\kappa')^{5/2}} e^{-(\kappa+x)C/2} \\
+ \frac{\sqrt{A^2 B}}{\kappa^{5/4} (\kappa')^{5/4}} e^{-(\kappa+x)C/2} + \frac{\sqrt{\kappa \kappa'}}{\kappa^{5/4} (\kappa')^{5/4}} e^{-(\kappa+2\kappa')C/2} \\
+ \frac{\sqrt{AAB}}{\kappa^{5/4} (\kappa')^{5/4}} e^{-(2\kappa+x')C/2} + \frac{\sqrt{A^2 B}}{\kappa^{5/4} (\kappa')^{5/4}} e^{-(\kappa+x')C}.
\]

The summation of the above expression over \(\kappa\) and \(\kappa'\) can be seen as an inner product of vectors with exponentially decaying terms and polynomially decaying terms, respectively. We hence apply Hölder’s inequality for sequence spaces on the summation of the above expression over \(\kappa\) and \(\kappa'\). We thereby obtain an upper bound of the sum in terms of the 1-norm of the vector with exponentially decaying terms and the \(\infty\)-norm of the vector with polynomially decaying terms:

\[
\sum_{\kappa, \kappa' \geq \nu} \sqrt{W_{\kappa, \kappa'}} \leq \sqrt{\kappa^2 B} \left( \sum_{X \geq \nu} X^{-5/2} \right)^2 + \frac{2\sqrt{AAB}}{N^{5/2}} \left( \sum_{X \geq \nu} X^{-5/2} \right) \frac{e^{-NC} (\kappa')^{5/2}}{(1-e^{-C})^2} \\
+ \frac{\sqrt{A^2 B}}{N^{5/2}} \frac{e^{-NC} (\kappa')^{5/2}}{(1-e^{-C})^2} + \frac{\sqrt{\kappa \kappa'}}{N^{5/2}} \frac{e^{-3NC} (\kappa')^{5/2}}{(1-e^{-C})^2} + \frac{\sqrt{A^2 B}}{N^{5/2}} \frac{e^{-NC}}{(1-e^{-C})^2}.
\]

Now the integral \(\int_{-\nu}^{\infty} x^{-5/2} dx\) is an upper bound of the sum \(\sum_{X \geq \nu} X^{-5/2}\) by the convexity of the integrand. Hence, \(\sum_{X \geq \nu} X^{-5/2} \leq \frac{2}{9} (N - \frac{1}{2})^{-3/2}\), and we can substitute this bound into our upper bound of the square of \(\sum_{\kappa, \kappa' \geq \nu} W_{\kappa, \kappa'}\) summed over the index \(0 \leq \ell' \leq L\) to obtain the result.

**4. Bounds on Hermite functions**

This section provides the main technical lemmas that are used to obtain error bounds on our approximation to our truncated transition amplitudes. The main technical tools that we use in this section are Alzer’s sharp bounds on the gamma function \([48]\) and bounds on Dominici’s asymptotic approximation of Hermite functions with error estimates by Kerman et al \([49]\).

**Lemma 4.1.** For all positive integers \(n\) and reals \(x \in [-\sqrt{n}, \sqrt{n}]\), we have \(|\psi_n(x)| < 1.74n^{-5/4}\).

**Proof.** This proof combines Alzer’s sharp bounds on the gamma function \([48]\) with uniform bounds on the envelope of the Hermite functions in the oscillatory region by Kerman et al \([49]\). Using Kerman et al’s result (see equations (2.1) and (1.4) in \([49]\)), for \(x \in [-\sqrt{n}, \sqrt{n}]\), we have

\[
|\psi_n(x)| \leq 2^{-3/4} \sqrt{35} \sqrt{n! \pi^{-1/2} n^{-2}} \left( \frac{n}{\sin \frac{x}{2}} \right)^{n/2} n^{-1}.
\]

Alzer’s sharp bounds for the gamma function are that for all \(n > 0\),

\[
1 < \frac{\Gamma(n+1)}{\sqrt{2\pi n \left( \frac{x}{2} \right)^n} \left( n \sinh \frac{x}{2} \right)^{n/2}} < 1 + \frac{1}{1620 n^3}.
\]
Note that for real $n \geq 1$, we have $1 \leq (n \sinh \frac{1}{n})^{n/2} < 1.085$. Hence, we have that for positive integers $n$,

$$\frac{\sqrt{n}}{\Gamma(n+1)} \frac{n^{n/2}}{\sqrt{\Gamma(n+1)}} < 0.9308(2^{n/2})n^{-1/4}.$$ 

Hence, Kerman et al’s upper bound on the envelope of the Hermite function for $x \in [-\sqrt{n}, \sqrt{n}]$ and $n \geq 1$ becomes

$$|\psi_n(x)| \leq 2^{-3/4}\sqrt{35}\frac{\pi^{-1/4}2^{-n/2}}{\sqrt{2}} \frac{\sqrt{n+1}}{\Gamma(n+1)} n^{-1} < 1.74n^{-5/4}. \quad \square$$

The next lemma provides a rather coarse upper bound on the absolute value of the Hermite function, with maximum utility in the monotonic region of the Hermite function.

**Lemma 4.2.** For all reals $|x| > 1$ and integers $n \geq 0$, we have $|\psi_n(x)| \leq 2^n \frac{n!n!}{\sqrt{\pi}} e^{-x^2/4}$.

**Proof.** Using the Maclaurin decomposition of the Hermite polynomial $H_n(x)$ [50], we obtain

$$|\psi_n(x)| \leq n! n(2x)^n \frac{e^{-x^2/2}}{\sqrt{2\pi n}} = \frac{2^n n!}{\sqrt{\pi}} n|x|^n e^{-x^2/2}.$$ 

It is easy to verify that $\sup_{x \in \mathbb{R}} \{n! n |x|^n e^{-x^2/4}\} = (\frac{2n}{e})^{n/2}$. Hence, when $|x| > 1$,

$$|\psi_n(x)| \leq 2^n \frac{n!n!}{\sqrt{\pi}} e^{-x^2/4}.$$ 

Lemma 4.3 provides upper bounds on the 1-norm of the product of Hermite functions in terms of the order of the Hermite functions and is crucial in obtaining upper bounds on our error estimates.

**Lemma 4.3.** For real numbers $a, b \neq 0$, let $c = \min(|a|, |b|)$. Let $j, k, n \in \mathbb{N}$ and $n \geq 1$. Then,

$$\int_{\mathbb{R}^2} \psi_n(ax + by)^2 |\psi_j(x)\psi_k(y)| \, dx \, dy \leq \frac{(1.74^2) \|\psi_j\|_1 \|\psi_k\|_1}{n^{5/2}} + (4.74)2^{j+k} \sqrt{\frac{1}{\sqrt{2}}^2} e^{-n/(8c^2)}.$$ 

**Proof.** We split the region over which the integral is performed into two overlapping regions $A_1$ and $A_2$ (see figure 1), where

$$A_1 = \{(x, y) : |ax| + |by| \leq \sqrt{n}\}$$

and

$$A_2 = \left\{(x, y) : x^2 + y^2 > \frac{\sqrt{n}}{2c}\right\}.$$ 

Then, using the Charlier–Cramér bound [50], which states that $\sup_{n \geq 1} |\psi_n(x)| \leq 1.086435 \frac{1}{\sqrt{2}} n^{3/2}$, and the uniform upper bound of the envelope of the Hermite polynomial in the oscillatory region as stated in lemma 4.1, we obtain

$$\int_{\mathbb{R}^2} \psi_n(ax + by)^2 |\psi_j(x)\psi_k(y)| \, dx \, dy \leq \int_{A_1} \frac{1.74^2}{n^{5/2}} |\psi_j(x)\psi_k(y)| \, dx \, dy + \int_{A_2} \frac{1.086435^2}{\sqrt{\pi}} |\psi_j(x)\psi_k(y)| \, dx \, dy.$$
The integral of $|\psi_j(x)\psi_k(y)|$ over the region $A_1$ is at most
\[
\frac{(1.74^2)\|\psi_j\|\|\psi_k\|}{n^{5/2}}.
\]

Using the exponential upper bound of lemma 4.2, the integral over the annulus region $A_2$ is at most
\[
\frac{1.086435^2}{\sqrt{\pi}} 2^{j+k} \frac{j!k!j^k}{e^{j+k}\pi} \int_{A_2} e^{-(r^2+y^2)/4} \, dx \, dy \\
\leq \frac{1.086435^2}{\sqrt{\pi}} 2^{j+k} \frac{j!k!j^k}{e^{j+k}\pi} 2\pi \int_{r>\sqrt{\frac{2}{\pi}}} r \, e^{-r^2/4} \, dr \\
= 1.086435^2 2^{j+k+1} \frac{j!k!j^k}{e^{j+k}} \left(2e^{-n(8\pi^2)}\right).
\]

Combining the upper bounds for regions $A_1$ and $A_2$ then gives the result.

The following lemma is needed to obtain upper bounds on the absolute value of $|j_{b,a,k,x',t',b',r',r}|$ and is similar to the preceding lemma.

**Lemma 4.4.** Let $0 \neq a, b \in \mathbb{R}, c = \min(|a|, |b|)$ and $j, k, n, n' \in \mathbb{N}$ where $n, n' \geq 1$. Then,
\[
\int_{\mathbb{R}^2} \psi_n(x) \psi_n(y) \int_{\mathbb{R}^2} \psi_n(x+by) \psi_n(ay+bx) \Theta_{w,x,y,z}(j,k;r) \, dx \, dy \\
\leq \frac{57.6\|\psi_n\|\|\psi_n\|}{(nn')^{5/2}} + (39.6)2^{j+k} \frac{j!k!j^k}{e^{j+k}} e^{-(n+n')/(8\pi^2)}.
\]

**Proof.** We split the region over which the integral is performed into two overlapping regions $A_1$ and $A_2$ (just as in the proof of lemma 4.3), where
\[
A_1 = \{(w,x,y,z) : |aw| + |by| \leq \sqrt{n}, |ax| + |bz| \leq \sqrt{n} \}
\]
and
\[
A_2 = \left\{(w,x,y,z) : w^2 + y^2 > \sqrt{n}/\sqrt{2c}, x^2 + z^2 > \sqrt{n}/\sqrt{2c} \right\}.
\]

Then using the Charlier–Cramér bound, and lemmas 4.1 and 4.2, we obtain
\[
\int_{\mathbb{R}^2} \psi_n(x) \psi_n(y) \int_{\mathbb{R}^2} \psi_n(x+by) \psi_n(ay+bx) \Theta_{w,x,y,z}(j,k;r) \, dx \, dy \\
\leq \int_{A_1} \frac{1.74^4}{(nn')^{5/2}} \|\Theta_{w,x,y,z}(j,k;r)\| \, dx \, dy \, dz \\
+ \int_{A_2} \frac{1.086435^4}{\pi} \|\Theta_{w,x,y,z}(j,k;r)\| \, dx \, dy \, dz.
\]

Now observe that we can express the kernel $\Theta_{w,x,y,z}(j,k;r)$ as
\[
\Theta_{w,x,y,z}(j,k;r) = e^{-\frac{1}{2}(y^2+z^2)} \exp \left[ -\frac{r}{1-r^2} (y-z)^2 \right] \psi_j(w) \psi_k(x),
\]
and hence the absolute value of our kernel has an upper bound that factorizes in the sense that
\[
|\Theta_{w,x,y,z}(j,k;r)| \leq e^{-\frac{1}{2}(y^2+z^2)} |\psi_j(w)| |\psi_k(x)|.
\]

Hence, the integral over the region $A_1$ is at most
\[
\frac{1.74^4(2\pi)\|\psi_j\|\|\psi_k\|}{(nn')^{5/2}}.
\]
The upper bound on the kernel also allows us to find that the integral over the region $A_2$ is at most

$$\frac{1.086435^4}{\pi} \frac{1}{2\pi} \int_{\mathbb{R}^2} e^{-\left(w^2+x^2\right)/4} \int_{\mathbb{R}^2} e^{-\left(y^2+z^2\right)/4} dw \, dx \, dz$$

$$\leq \frac{1.086435^4}{\pi^{3/2}} \frac{1}{2\pi} \int_{\mathbb{R}^2} e^{-\left(r_1^2+r_2^2\right)/4} \int_{\mathbb{R}^2} e^{-\left(r_1^2+r_2^2\right)/4} dr_1 \, dr_2$$

$$\leq \frac{1.086435^4(2\pi)^2}{\pi^{3/2}} \int_{\mathbb{R}^2} e^{-\left(r_1^2+r_2^2\right)/4} \int_{\mathbb{R}^2} e^{-\left(r_1^2+r_2^2\right)/4} dr_1 \, dr_2$$

$$\leq (39.6)^{2j+k} \int_{\mathbb{R}^2} e^{-\left(r_1^2+r_2^2\right)/4} dr_1 \, dr_2$$

Combining our upper bounds on the integrals in the regions $A_1$ and $A_2$ thereby gives the result.

5. A case study: off-resonant weakly coupled oscillators

In this section, we perform a case study of the dynamics of our physical model when the oscillators are off-resonant and weakly coupled. In agreement with the standard results of perturbation theory, we find negligible amplitude damping in the truncated dynamics of our system. Moreover, we show that the leakage error is the dominant error process and can be mitigated via quantum error correction.

5.1. Parameters of the physical model and the truncated channel

The amount of truncation in our truncated channel $\mathcal{N}$ is quantified by the parameter $L = 2$ and the order of our approximation to the truncated channel is quantified by the parameter $N = 6$ (see (29) for the definition of the truncated transition amplitudes). We restrict the analysis of our truncated channels to a four-level system by setting the parameter $D = 3$.

Table 1 shows the parameters used for our physical model. We use SI units. The output parameters are numerically computed using floating point numbers with 1024 bits of precision and are shown up to ten decimal places. For our choice of parameters, the positive constants $A\bar{A}B, \bar{A}B^2, A\bar{A}B, \bar{A}^2B \leq 10^{-288}$ and are negligible, and hence remark 3.2 holds.

| Input parameters | Output parameters | Other parameters and bounds |
|------------------|-------------------|---------------------------|
| $m_i$ 10^{-6} (kg) | $\omega_x$ 1000 499 875 062 4610 (Hz) | $\|\psi_0\|$ $\leq$ 1.882 792 527 553 4299 |
| $m_v$ 2 x 10^{-6} (kg) | $\omega_y$ 10 000 024 999 968 7501 (Hz) | $\|\psi_1\|$ $\leq$ 2.124 503 864 054 394 |
| $\omega_{x,0}$ 10^6 (Hz) | $\omega_y$ 1001 004 543 833 2595 (Hz) | $\|\psi_2\|$ $\leq$ 2.285 324 224 284 738 |
| $\omega_{y,0}$ 10^7 (Hz) | $\omega_y$ 10 000 025 000 177 9494 (Hz) | $\|\psi_3\|$ $\leq$ 2.410 237 758 997 186 |
| $k$ 100 (kg s^{-2}) | $u_1$ 10 000 025 000 177 9494 | $v_1$ -0.000 045 1621 |
| $r$ 0 | $u_2$ 0.000 003 1958 | $v_2$ 1.000 000 000 |

Table 1.
5.2. Approximate dynamics of the truncated channel

We numerically evaluate approximate truncated transition amplitudes \( A_{a,b}^{t} \) corresponding to the transitions within the lowest energy levels of the system. The evaluation of each such approximate truncated transition amplitude \( A_{a,b}^{t} \) is a sum of 7203 terms for our choice of \( L = 2 \) and \( N = 6 \). We obtain the corresponding error bounds of our approximation from remark 3.4 with \( N' = 15 \). The error of each of our approximate truncated transition amplitudes is at most 0.00084—a negligible amount. We plot the magnitudes of the non-negligible truncated transition amplitudes in figure 2.

Numerically, we find that the non-negligible terms of \( A_{a,b}^{t} \) have values of 0 \( \leq a, b \leq 1 \) and 0 \( \leq a', b' \leq 3 \) that satisfy the relation

\[
\frac{a' - a}{2}, \frac{b' - b}{2} \in \mathbb{Z}.
\] (38)

The above relation holds for two reasons. First, the conservation of the parity of all truncated transition amplitudes as stated in remark 3.3 implies that the parity of \( a + b \) equals the parity of \( a' + b' \). Second, the other negligible transitions are in agreement with the results of using perturbation theory on off-resonant and weakly coupled harmonic oscillators. Also note that the negligible damping from the first excited state to the ground state of our truncated channel suggests that the coupled oscillator model is inconsistent with the phenomenon of amplitude damping [23] even at zero temperature.

The CJ operator of the finite input and output dimension channel \( \Phi \) with the Kraus set \( \mathcal{K} \) is the linear operator

\[
\chi_{\Phi} := \sum_{K} |K\rangle \langle K| = \sum_{j,f} \left( \sum_{K \in \mathcal{K}} \sum_{K' \in \mathcal{K}} K_{j,K}^{*} K'_{f,K} |j_{K'}, f_{K}\rangle \langle k_{K}, k'_{K}| \right),
\] (39)

where the linear map \( |\cdot\rangle : L(H, K) \to K \otimes H \) is a stacking isomorphism such that

\[
\left| \sum_{i,j} a_{i,j} |i_{K}\rangle \langle j_{K'}| \right| := \sum_{i,j} a_{i,j} |i_{K}\rangle |j_{K'}|. \]

We now construct a quantum operation \( \mathcal{A} \) to approximate the truncated channel \( \mathcal{N} \). Abbreviating our approximate truncated transition amplitudes as \( A_{a,b}^{t} := A_{a,b}^{t} \), our
approximation to the CJ operator of our truncated channel is

\[
\chi := \begin{pmatrix}
A_{0000} & A_{0002} & A_{0101} & A_{0103} \\
A_{0020} & A_{0022} & A_{0202} & A_{0204} \\
A_{1010} & A_{1012} & A_{1111} & A_{1113} \\
A_{1030} & A_{1032} & A_{1131} & A_{1133}
\end{pmatrix}
\]

(40)

where the bases labeled by the rows and columns are \(|0, 0\rangle, |2, 0\rangle, |1, 1\rangle, |3, 1\rangle\) and \(|0, 0\rangle, |2, 0\rangle, |1, 1\rangle, |3, 1\rangle\), respectively. The first and second entries of our bras and kets correspond to the output and input Hilbert spaces of the truncated map, respectively. We plot the absolute values of some of these non-negligible matrix elements in figure 2.

Let \(\chi\) have the spectral decomposition \(\chi = \sum_{i=1}^{\infty} \lambda_i |\lambda_i\rangle \langle \lambda_i|\), where \(|\lambda_i\rangle \langle \lambda_i|\) are orthogonal projectors and the eigenvalues \(\lambda_i\) are in a non-increasing order. For \(\lambda_i \geq 0\), let \(A_i\) be the image of the inverse map of the linear operator \(|\cdot\rangle\rangle\) acting on \(\sqrt{\lambda_i}|\lambda_i\rangle\). Numerically diagonalizing the matrix \(\chi\) shows that it has only one dominant eigenvalue. Hence, we use the quantum operation \(A(\nu) := A_1 \nu A_1^\dagger\) to approximate the truncated channel \(\mathcal{N}\), where \(A_1 = \sqrt{\lambda_1}(k_0|0\rangle \langle 0| + k_2|2\rangle \langle 0| + k_3|1\rangle \langle 1| + k_4|3\rangle \langle 1|)\) and \(|\lambda_1\rangle = |0, 0\rangle + k_2|2, 0\rangle + k_3|1, 1\rangle + k_4|3, 1\rangle\). Observe that for \(i, j \in \{0, 1, 2, 3\}\), we have

\[
A(|i\rangle \langle j|) = \lambda_i (k_i|i\rangle + k_{i+2}|i+2\rangle)(k_j^*|j\rangle + k_{j+2}^*|j+2\rangle).
\]

(41)

5.2.1. Leakage error. The leakage error, a dominant process of our model, occurs when low-energy states transition into higher energy states within the quantum system. We derive lower bounds on the minimum amount of qubit leakage in our system, when the quantum channel is \(\Phi_t\) with the Kraus set \(\mathcal{K}_t\) given by (15). For qubit leakage to occur, it suffices to have the strict inequality

\[
\text{Leakage}(\Phi_t, \rho) := \sum_{i=2}^{\infty} \langle i|\Phi_t(\rho)|i\rangle > 0,
\]

(42)

for some density operator \(\rho\) supported on the span of \(|0, 0\rangle\) and \(|1, 1\rangle\). The above expression quantifies the amount of leakage from the qubit state space of our system.

We proceed to obtain a strictly positive lower bound on \(\text{Leakage}(\Phi_t, \rho)\). If \(\Phi_t = \mathcal{N} + \mathcal{M}\) for some completely positive maps \(\mathcal{N}\) and \(\mathcal{M}\), then the complete positivity of \(\mathcal{N}\) and \(\mathcal{M}\) implies that \(\text{Leakage}(\Phi_t, \rho) \geq \text{Leakage}(\mathcal{N}, \rho)\). Hence, it suffices to obtain a lower bound for \(\text{Leakage}(\mathcal{N}, \rho)\). For our application, \(\mathcal{N}\) is our truncated channel.

Assume that the initial state of the system is \(\rho = \frac{1}{2}(|0, 0\rangle \langle 0, 0| + |1, 1\rangle \langle 1, 1|)\), the maximally mixed state in the qubit space. Then, the leakage of the truncated channel \(\mathcal{N}\) is at least

\[
\frac{1}{2}\left(\mathcal{L}_t^{(0,0)\rightarrow(2,2)} + \mathcal{L}_t^{(1,1)\rightarrow(3,3)}\right).
\]

Thus, we have that \(\text{Leakage}(\mathcal{N}, \rho) \geq \frac{1}{2}\left(|A_{L,N,t}^{(0,0)\rightarrow(2,2)}| + |A_{L,N,t}^{(1,1)\rightarrow(3,3)}|\right) - \epsilon\), where \(\epsilon\) is given as the upper bound in theorem 3.1. In view of the data given in figure 2, the amount of qubit leakage can actually be quite substantial. In particular, when \(t = 5 \times 10^{-6}\), the amount of leakage of \(\Phi_t\) is at least 0.4, which is substantially larger than 0.

The large amount of leakage from our qubit state highlights the importance of accounting for transitions of low-energy states into excited states in oscillator systems, and also the problem of using the lowest two energy eigenstates as a basis to encode our qubit.

\footnote{The matrix \(\chi\) is symmetric and hence has real eigenvalues.}
5.2.2. Quantum error correction versus no quantum error correction. We consider a universe with four harmonic oscillators $X_1, X_2, Y_1$ and $Y_2$. We identify the oscillators $X_1$ and $X_2$ as $x$-type oscillators and the oscillators $Y_1$ and $Y_2$ as $y$-type oscillators, with their parameters given by Table 1. Assume that there are only $X_1$–$Y_1$ couplings and $X_2$–$Y_2$ couplings in our universe. Suppose that a maximally entangled two-qubit state is initialized in the $X_1$ and $X_2$ oscillators supported on their two lowest energy levels. We assume that the oscillators $Y_1$ and $Y_2$ are initialized in the ground state. We obtain a lower bound on the fidelity of the time-evolved states when instantaneous, identical and independent recovery operations are performed on oscillators $X_1$ and $X_2$. Denoting our truncated channel and recovery channel on a single system oscillator by $N$ and $\mathcal{R}$, respectively, our lower bound on the output fidelity is

$$f_R = \langle \Phi | (\mathcal{R} \otimes \mathcal{R}) \circ (N_1 \otimes N_2) | \Phi \rangle,$$

(43)

where $|\Phi\rangle = (|0\rangle_1, 0\rangle_2 + |1\rangle_1, 1\rangle_2)/\sqrt{2}$. We now proceed to obtain a lower bound on the entanglement fidelity of our time-evolved maximally entangled state, with and without recovery. The maximally entangled state on two qubits written as a density matrix is

$$|\Phi\rangle\langle\Phi| = \frac{1}{2} \sum_{i,j \in \{0,1\}} |i, i\rangle\langle j, j|.$$

(44)

By linearity, the action of our truncated channels on the maximally entangled state gives

$$(N_1 \otimes N_2)|\Phi\rangle = \frac{1}{2} \sum_{i,j \in \{0,1\}} N_i(i\rangle\langle j|) \otimes N_j(i\rangle\langle j|).$$

(45)

Let us denote the error of the truncated transition amplitude of $A_{ij}^{x,y}$ to be $\epsilon_{ij}^{x,y}$ so that

$$(N_1 \otimes N_2)|\Phi\rangle = \frac{1}{2} \sum_{i,j \in \{0,1\}} (A_{ij} + \epsilon_{ij}^{x,y})(A_{ij} + \epsilon_{ij}^{y,x})|i, i\rangle\langle j, j|.$$

(46)

If we perform no recovery operation, $\mathcal{R}$ is just the identity map $\mathcal{I}$, and we have

$$f_T = \langle \Phi | (N_1 \otimes N_2) | \Phi \rangle.$$

(47)

Dropping the labels on the Hilbert spaces of our bras and kets, we can use (46) to find that

$$f_T = \frac{1}{2} \langle (0, 0) + (1, 1) | (N_1 \otimes N_2) | (0, 0) + (1, 1) \rangle$$

$$= \frac{1}{4} \sum_{i,j \in \{0,1\}} (A_{ij} + \epsilon_{ij}^{x,y})(A_{ij} + \epsilon_{ij}^{y,x})|i, i\rangle\langle j, j|$$

$$\geq \frac{1}{4} (\Lambda_{0000}^2 + \Lambda_{1111}^2 + \Lambda_{0010}^2 + \Lambda_{1001}^2 - 8\epsilon^2 + \epsilon^2)$$

(48)

where $\epsilon \leq 0.00084$. Note that $\Lambda_{0010}^2 + \Lambda_{1001}^2$ can be negative.

The Barnum–Knill recovery operator $\mathcal{R}^{BK}$ [25] and the Tyson–Beny–Oreshkov quadratic recovery operator [29, 30] are near-optimal recovery operators defined with respect to a quantum operation $A$ and a state $\rho$, and are equivalent when $A$ has only one Kraus operator.
For our application, we study the Barnum–Knill recovery, with \( \rho = (|0\rangle\langle 0| + |1\rangle\langle 1|)/2 \) and quantum operation \( \mathcal{A} \) approximating the truncated channel \( \mathcal{N} \). Our choice of \( \rho \) shows that our quantum information is encoded in the trivial quantum code (no encoding). For our application, the Barnum–Knill recovery operator, which is also a quantum operation, is defined as

\[
\mathcal{R}_{\text{BK}}(\nu) = A_1^+ A_1^{-1/2} + \nu (A_1^+ A_1^{-1/2}) + A_1
\]

where \( (A_1^+ A_1^{-1/2}) \) is the square root of the pseudo-inverse of the operator \( A_1^+ A_1^{-1} \). When we use the Barnum–Knill recovery operation \( \mathcal{R}_{\text{BK}} \), the fidelity of recovery is

\[
f_{\text{BK}} = \langle \Phi_1 | (\mathcal{R}_{\text{BK}} \otimes \mathcal{R}_{\text{BK}}) \circ (\mathcal{N} \otimes \mathcal{N})) | \Phi_1 \rangle \geq \frac{2}{4} (\lambda_2^2 + |\lambda_3| + |\lambda_4| + 2\epsilon^2).
\]

We plot lower bounds of the fidelity with and without Barnum–Knill recovery in figure 3 and demonstrate that a fidelity of more than 60% is still possible in spite of the leakage error and the use of truncated quantum channels in our analysis.

6. Discussions

The system we consider is described by a quantum harmonic oscillator coupled through a spring-like interaction to another initially decoupled harmonic oscillator. We provide approximations to the truncated transition amplitudes of such a system. The converging error bound of such approximations is our main result. Properties of the integrals of products of Hermite functions lie at the heart of the proof. It is also worth noting that any ensemble of harmonic oscillators with spring-like coupling can be analyzed similarly.

We also show numerically that in agreement with the intuition from perturbation theory, when the oscillators are off-resonant and weakly coupled, amplitude damping is a negligible physical process. We also use our truncated channel representation to show that the qubit leakage can be a dominant physical process, and how Barnum–Knill recovery can help protect a maximally entangled state stored in two oscillators each coupled independently to distinct zero-temperature harmonic baths, in the paradigm of off-resonant and weak coupling between the system and a zero-temperature bath.
Acknowledgment

We would like to thank Si-Hui Tan and the referees for helpful suggestions.
