ON THE KOHANOV AND KNOT FLOER HOMOLOGIES OF QUASI-ALTERNATING LINKS

CIPRIAN MANOLESCU AND PETER OZSVÁTH

Abstract. Quasi-alternating links are a natural generalization of alternating links. In this paper, we show that quasi-alternating links are “homologically thin” for both Khovanov homology and knot Floer homology. In particular, their bigraded homology groups are determined by the signature of the link, together with the Euler characteristic of the respective homology (i.e., the Jones or the Alexander polynomial). The proofs use the exact triangles relating the homology of a link with the homologies of its two resolutions at a crossing.

1. Introduction

In recent years, two homological invariants for oriented links $L \subset S^3$ have been studied extensively: Khovanov homology and knot Floer homology. Our purpose here is to calculate these invariants for the class of quasi-alternating links introduced in [19], which generalize alternating links.

The first link invariant we will consider in this paper is Khovanov’s reduced homology ([5], [6]). This invariant takes the form of a bigraded vector space over $\mathbb{Z}/2\mathbb{Z}$, denoted $\tilde{\text{Kh}}_{i,j}(L)$, whose Euler characteristic is the Jones polynomial in the following sense:

$$\sum_{i \in \mathbb{Z}, j \in \mathbb{Z} + \frac{l}{2}} (-1)^i q^j \text{rank} \tilde{\text{Kh}}_{i,j}(L) = V_L(q),$$

where $l$ is the number of components of $L$. The indices $i$ and $j$ are called the homological and the Jones grading, respectively. (In our convention $j$ is actually half the integral grading $j$ from [5].) The indices appear as superscripts because Khovanov’s theory is conventionally defined to be a cohomology theory. It is also useful to consider a third grading $\delta$, described by the relation $\delta = j - i$.

Khovanov’s original definition gives a theory whose Euler characteristic is the Jones polynomial multiplied by the factor $q^{1/2} + q^{-1/2}$; for the reduced theory, the Euler characteristic is the usual Jones polynomial, i.e., normalized so that it takes the value 1 on the unknot, cf. [6]. Note that $\tilde{\text{Kh}}$ can be also be defined with integer coefficients, but then it depends on the choice of a component of the link. Nevertheless, $\tilde{\text{Kh}}$ is a link invariant over $\mathbb{Z}/2\mathbb{Z}$; see [19, Section 5] or [29, Section 3].

The other homological link invariant that we consider in this paper is knot Floer homology. This theory was independently introduced by Szabó and the second author in [15], and by Rasmussen [27]. In its simplest form, it is a bigraded Abelian group $\widehat{HF}K_i(L, j)$ whose content is as follows:

CM was supported by a Clay Research Fellowship.
PSO was supported by NSF grant numbers DMS-0505811 and FRG-0244663.
Euler characteristic is (up to a factor) the Alexander-Conway polynomial $\Delta_L(q)$:

$$\sum_{j \in \mathbb{Z}, i \in \mathbb{Z}+\mathbb{Z}} (-1)^{i+j+\frac{l-1}{2}} q^{i+j} \text{rank} \hat{HFK}_i(L, j) = (q^{-1/2} - q^{1/2})^{l-1} \cdot \Delta_L(q).$$

Knot Floer homology was originally defined using pseudo-holomorphic curves, but there are now also several combinatorial formulations available, cf. [10], [11], [30], [24]. The two gradings $i$ and $j$ are called the Maslov and Alexander gradings respectively; we also set $\delta = j - i$ as above. Knot Floer homology detects the genus of a knot [17], as well as whether a knot is fibered [25]. There exists also an improvement, called link Floer homology ([22], [23]), which detects the Thurston norm of the link complement, but that theory will not be discussed in this paper. Also, even though $\hat{HFK}$ can be defined with integer coefficients, in this paper we will only consider it with coefficients in the field $\mathbb{F} = \mathbb{Z}/2\mathbb{Z}$.

For many classes of links (including most knots with small crossing number), the Khovanov and knot Floer homologies over $R = \mathbb{Z}$ or $\mathbb{F}$ take a particularly simple form: they are free $R$-modules supported in only one $\delta$-grading. We call such links Khovanov homologically thin (over $R$), or Floer homologically thin (over $R$), depending on which theory we refer to. Various versions of these definitions appeared in [2], [27], [6], [28]. Further, it turns out that typically the $\delta$-grading in which the homology groups are supported equals $-\sigma/2$, where $\sigma$ is the signature of the link. When this is the case, we say that the link is (Khovanov or Floer) homologically $\sigma$-thin. (Floer homologically $\sigma$-thin knots were called perfect in [26].)

If a link $L$ is homologically $\sigma$-thin over $R = \mathbb{Z}$ or $\mathbb{F}$ for a bigraded theory $\mathcal{H}$ (where $\mathcal{H}$ could denote either $\tilde{Kh}$ or $\hat{HFK}$), then $\mathcal{H}(L)$ is completely determined by the signature $\sigma$ of $L$ and the Euler characteristic $P(q)$ of $\mathcal{H}$ (the latter being either the Jones or a multiple of the Alexander polynomial). Indeed, if $P(q) = \sum a_j q^j$, we must have:

$$\mathcal{H}^{i,j}(L) \simeq \begin{cases} R[a_j] & \text{if } i = j + \frac{\sigma}{2} \\ 0 & \text{otherwise.} \end{cases}$$

In the world of Khovanov homology, the fact that the vast majority (238) of the 250 prime knots with up to 10 crossings are homologically $\sigma$-thin was first observed by Bar-Natan, based on his calculations in [2]. Lee [7] showed that alternating links are Khovanov homologically $\sigma$-thin. Since 197 of the prime knots with up to 10 crossings are alternating, this provides a partial explanation for Bar-Natan’s observation.

At roughly the same time, a similar story unfolded for knot Floer homology. Rasmussen [26] showed that 2-bridge knots are Floer homologically $\sigma$-thin; and this result was generalized in [16] to all alternating knots.

In this paper we generalize these results to a larger class of links, the quasi-alternating links of [19]. Precisely, $\mathcal{Q}$ is the smallest set of links satisfying the following properties:

- The unknot is in $\mathcal{Q}$;
- If $L$ is a link which admits a projection with a crossing such that
  1. both resolutions $L_0$ and $L_1$ at that crossing (as in Figure 1) are in $\mathcal{Q}$,
  2. $\det(L) = \det(L_0) + \det(L_1)$,
then $L$ is in $\mathcal{Q}$.

The elements of $\mathcal{Q}$ are called quasi-alternating links. It is easy to see (cf. [19 Lemma 3.2]) that alternating links are quasi-alternating.

In this paper we prove the following:

**Theorem 1.** Quasi-alternating links are Khovanov homologically $\sigma$-thin (over $\mathbb{Z}$).

**Theorem 2.** Quasi-alternating links are Floer homologically $\sigma$-thin (over $\mathbb{Z}/2\mathbb{Z}$).
For knots with up to nine crossings, Theorem 1 and Theorem 2 provide an almost complete explanation for the prevalence of homological $\sigma$-thinness (over the respective coefficient ring). Indeed, among the 85 prime knots with up to nine crossings, only two ($8_{19}$ and $9_{42}$) are not Khovanov homologically $\sigma$-thin, and these are also the only ones which are not Floer homologically $\sigma$-thin. By the results of [19], [9] and [1], 82 of the 83 remaining knots are quasi-alternating. (Among them, 74 are alternating.) This leaves only the knot $9_{46}$, which the authors do not know if it is quasi-alternating.

In general it is difficult to decide whether a larger, homologically $\sigma$-thin knot is quasi-alternating. It remains a challenge to find homologically $\sigma$-thin knots that are not quasi-alternating; $9_{46}$ could be the first potential example.

A few words are in order about the strategy of proof and the organization of the paper. Both Theorem 1 and Theorem 2 are consequences of the unoriented skein exact triangles satisfied by the respective theories. For Khovanov homology, this exact triangle (which relates the homology of $L$ to that of its resolutions $L_0$ and $L_1$, cf. Figure 1), is immediate from the definition of the homology groups. The only new ingredient used in the proof of Theorem 1 is an observation about relating the gradings to the signature. We explain this in Section 2 of the paper. In fact, the proof of Theorem 1 is an adaptation of the proof of the corresponding fact for alternating links due to Lee [7].

For knot Floer homology, an unoriented skein exact triangle was described by the first author in [9]. In that paper, the maps in the triangle were ungraded. In Section 3 we show that they actually respect the $\delta$-grading, up to a well-determined shift. This will imply Theorem 2. It is interesting to note that this strategy is quite different from the earlier proofs for two-bridge and alternating links, [27], [16].

We remark that Theorem 2 has a number of formal consequences. The full version of knot Floer homology is a graded, filtered chain complex over the polynomial algebra $\mathbb{F}[U]$. It was shown in [16] Theorem 1.4 and the remark immediately after] that for Floer homologically $\sigma$-thin knots, their full complex (up to equivalence) is determined by their Alexander polynomial and signature. Theorem 2 implies then that this is true for quasi-alternating knots. Furthermore, according to [20] and [21], the full knot Floer complex has enough information to determine the Heegaard Floer homology of any Dehn surgery on that knot. Thus, the Floer homologies (over $\mathbb{F}$) of Dehn surgeries on quasi-alternating knots are determined by the Alexander polynomial, the signature, and the surgery coefficient; we refer to [16], [20], [21] for the precise statements.

It is natural to expect Theorem 2 to hold also over $\mathbb{Z}$. Note that Theorem 2 combined with the universal coefficients theorem, implies that quasi-alternating links are Floer homologically $\sigma$-thin over $\mathbb{Q}$.

Acknowledgments. We would like to thank John Baldwin, Matthew Hedden, Robert Lipshitz, Jacob Rasmussen and Sucharit Sarkar for helpful conversations.
2. THE EXACT TRIANGLE FOR KHovanov HOMOLOGY

2.1. The Gordon-Litherland Formula. Let us review the definition of the Goeritz matrix, as well as the Gordon-Litherland formula for the signature, following [3].

Consider an oriented link $L$ in $S^3$ with a regular, planar projection, and let $D$ be the corresponding planar diagram. The complement of the projection in $\mathbb{R}^2$ has a number of connected components, which we call regions. We color them in black and white in checkerboard fashion. Let $R_0, R_1, \ldots, R_n$ be the white regions. Assume that each crossing is incident to two distinct white regions. To each crossing $c$ we assign an incidence number $\mu(c)$, as well as a type (I or II), as in Figure 2. Note that the sign of the crossing is determined by its incidence number and type.

Set
$$\mu(D) = \sum_{c \text{ of type II}} \mu(c).$$

The Goeritz matrix $G = G(D)$ of the diagram $D$ is defined as follows. For any $i, j \in \{0, 1, \ldots, n\}$ with $i \neq j$, let
$$g_{ij} = -\sum_{c \in R_i \cap R_j} \mu(c).$$

Set also
$$g_{ii} = -\sum_{i \neq j} g_{ij}.$$

Then $G$ is the $n \times n$ symmetric matrix with entries $g_{ij}$, for $i, j \in \{1, \ldots, n\}$.

Gordon and Litherland showed that the signature of $L$ is given by the formula
$$\sigma(L) = \text{signature}(G) - \mu(D).$$

(We use the convention that the signature of the right-handed trefoil is $-2$.) Also, the determinant $\det(L)$ of a link $L$ can be defined as the non-negative integer
$$\det(L) = |\det(G)|.$$

2.2. The Signature of Resolutions. Let $L \subset S^3$ be an oriented link with a fixed planar projection as before. Fix now a crossing $c_0$ in the corresponding planar diagram. If the crossing is positive (resp. negative), we set $L_+ = L$ (resp. $L_- = L$) and let $L_-$ (resp. $L_+$) be the link obtained form $L$ by changing the sign of the crossing. Further, we denote by $L_v$ and $L_h$ the oriented and unoriented resolutions of $L$ at that crossing, cf. Figure 3. (We choose an arbitrary orientation for $L_h$.)

To make the connection with Figure 1 note that if $L = L_+$, then $L_0 = L_v$ and $L_1 = L_h$, while if $L = L_-$, then $L_0 = L_h$ and $L_1 = L_v$.

Denote by $D_+, D_v, D_h$ the planar diagrams of $L_+, L_v, L_h$, respectively, differing from each other only at the chosen crossing $c_0$.

The first equality in the lemma below (without the sign) is due to Murasugi [12]; the second is also inspired by a result of Murasugi from [13].
Lemma 3. Suppose that $\det(L_v), \det(L_h) > 0$ and $\det(L_+) = \det(L_v) + \det(L_h)$. Then:

$$\sigma(L_v) - \sigma(L_+) = 1$$

and

$$\sigma(L_h) - \sigma(L_+) = e,$$

where $e$ denotes the difference between the number of negative crossings in $D_h$ and the number of such crossings in $D_+$.

Proof. Construct the Goeritz matrices $G_+ = G(D_+), G_v = G(D_v)$ and $G_h = G(D_h)$ in such a way that $c_0$ is of Type I (and incidence number $-1$) in $D_+$, and the white region $R_0$ (the one not appearing in the Goeritz matrix) is as in Figure 4.

Observe now that $G_+$ and $G_h$ are bordered matrices of $G_v$. More precisely, if $G_v$ is an $n \times n$ symmetric matrix, then there exists $a \in \mathbb{R}$ and $v = (v_1, \ldots, v_n) \in \mathbb{R}^n$ such that

$$G_+ = \begin{pmatrix} a & v \\ v^T & G_v \end{pmatrix}; \quad G_h = \begin{pmatrix} a + 1 & v \\ v^T & G_v \end{pmatrix}.$$

Without loss of generality (after an orthonormal change of basis), we can assume that $G_v$ is diagonal, with diagonal entries $\alpha_1, \ldots, \alpha_n$. Note that these are nonzero because $\det(L_v) = |\det(G_v)| \neq 0$.

The bilinear form associated to $G_+$ can be written as

$$aX^2 + 2 \sum_{i=1}^{n} v_iXX_i + \sum_{i=1}^{n} \alpha_iX_i^2,$$

or

$$\left(a - \sum_{i=1}^{n} \frac{v_i^2}{\alpha_i}\right)X^2 + \sum_{i=1}^{n} \alpha_i \left(XX_i + \frac{v_i}{\alpha_i}X\right)^2.$$

A similar formula holds for the form of $G_h$, but with $a$ replaced by $a + 1$.

If we set

$$\beta = a - \sum_{i=1}^{n} \frac{v_i^2}{\alpha_i},$$
then
\[ \det(G_+) = \beta \cdot \det(G_v), \quad \det(G_h) = (\beta + 1) \cdot \det(G_v). \]

By the condition on the determinants in the hypothesis, \(|\beta| = |\beta + 1| + 1\), so we must have \(\beta < -1\). Therefore, when we diagonalize the bilinear forms, for \(G_+\) (resp. \(G_h\)) we get one additional negative coefficient \((\beta, \text{resp. } \beta + 1)\) as compared to \(G_v\). Thus,
\[
(2) \quad \text{signature}(G_+) = \text{signature}(G_h) = \text{signature}(G_v) - 1.
\]

Since \(c_0\) is of Type I, we also have \(\mu(D_+) = \mu(D_v)\). Together with the Gordon-Litherland formula \([1]\), these identities imply
\[
\sigma(L_+) = \sigma(L_v) - 1.
\]

Next, observe that when we change the direction of an arc at a crossing, both the sign and the type of the crossing are reversed, but the incidence number remains the same.

Using (1) and (2) again, we get
\[
\sigma(L_+) = \sigma(L_h) + e,
\]
as desired. \(\square\)

2.3. An unoriented skein exact triangle. The following proposition is a simple consequence of the definition of Khovanov cohomology. It is implicit in \([3]\), and also appeared in Viro’s work \([31]\). The statement below, with the precise gradings, is taken from Rasmussen’s review \([28]\, Proposition 4.2\). It is written there in terms of Khovanov’s unreduced cohomology, but it works just as well for the reduced version \(\widehat{Kh}\), which we use in this paper. We work over \(\mathbb{Z}\), so to define the reduced homology we need to mark a component for each link appearing in the triangle; we do this by marking the same point on their diagrams, away from the crossing where the links differ.

**Proposition 4.** (Khovanov, Viro, Rasmussen) There are long exact sequences
\[
\cdots \to \widehat{Kh}^{-i-e-1,j-\frac{3e}{2}-1}(L_h) \to \widehat{Kh}^{-i,j}(L_+) \to \widehat{Kh}^{-i,j-\frac{1}{2}}(L_v) \to \widehat{Kh}^{-i-e,j-\frac{3e}{2}-1}(L_h) \to \cdots
\]
and
\[
\cdots \to \widehat{Kh}^{-i,j+\frac{1}{2}}(L_v) \to \widehat{Kh}^{-i,j}(L_-) \to \widehat{Kh}^{-i-e+1,j-\frac{3e}{2}+1}(L_h) \to \widehat{Kh}^{-i+1,j+\frac{1}{2}}(L_v) \to \cdots
\]
where \(e\) is as in the statement of Lemma \(3\).

If we forget about \(i\) and \(j\) and just keep the grading \(\delta = j - i\), the two triangles become
\[
\cdots \to \widehat{Kh}^{-i+\frac{3}{2}}(L_h) \to \widehat{Kh}^{-i}(L_+) \to \widehat{Kh}^{-i+\frac{1}{2}}(L_v) \to \widehat{Kh}^{-i-\frac{3}{2}-1}(L_h) \to \cdots
\]
and
\[
\cdots \to \widehat{Kh}^{-i+\frac{1}{2}}(L_v) \to \widehat{Kh}^{-i}(L_-) \to \widehat{Kh}^{-i-\frac{3}{2}}(L_h) \to \widehat{Kh}^{-i-\frac{1}{2}}(L_v) \to \cdots
\]
Proposition 5. Let \( L \) be a link and \( L_0, L_1 \) its two resolutions at a crossing as in Figure 4. Assume that \( \det(L_0), \det(L_1) > 0 \) and \( \det(L) = \det(L_0) + \det(L_1) \). Then there is an exact triangle:

\[
\cdots \to \overline{\text{Kh}}^+ \frac{\sigma(L_1)}{2} (L_1) \to \overline{\text{Kh}}^+ \frac{\sigma(L)}{2} (L) \to \overline{\text{Kh}}^+ \frac{\sigma(L_0)}{2} (L_0) \to \overline{\text{Kh}}^+ \frac{\sigma(L_1)}{2} (L_1) \to \cdots
\]

Proof. When the given crossing in \( L \) is positive, this is a re-writing of the triangle \( \Box \), taking into account the result of Lemma 3. Note that when following three consecutive maps in the triangle the grading decreases by one; thus, the grading change for the map between the homologies of the two resolutions is determined by the grading change for the other two maps.

The case when the crossing is negative is similar. \( \Box \)

Proof of Theorem \( \mathbb{I} \). Note that any quasi-alternating link has nonzero determinant; this follows easily from the definition. The desired result is then a consequence of Proposition 5: the unknot is homologically \( \sigma \)-thin and, because of the exact triangle, if \( L_0 \) and \( L_1 \) are homologically \( \sigma \)-thin, then so is \( L \). \( \Box \)

3. The exact triangle for knot Floer homology

In this section we assume that the reader is familiar with the basics of knot Floer homology (including the version with several basepoints), cf. \cite{15, 27, 22, 10}. Throughout this section we will work with coefficients in the field \( \mathbb{F} = \mathbb{Z}/2\mathbb{Z} \).

3.1. Heegaard diagrams and periodic domains. We start with a few generalities about periodic domains in Heegaard diagrams. Our discussion is very similar to the ones in \cite{18} Section 2.4 and \cite{22} Section 3.4, except that here we do not ask for the periodic domains to avoid any basepoints.

Let \( \Sigma \) be a Riemann surface of genus \( g \). A collection \( \alpha = (\alpha_1, \ldots, \alpha_n) \) of disjoint, simple closed curves on \( \Sigma \) is called good if the span \( S_\alpha \) of the classes \( [\alpha_i] \) in \( H_1(\Sigma; \mathbb{Z}) \) is \( g \)-dimensional. If \( \alpha \) is such a collection, we view (the closures of) the components of \( \Sigma - (\cup \alpha_i) \) as two-chains on \( \Sigma \) and denote by \( \Pi_\alpha \) their span. Note that \( \Pi_\alpha \) is a free Abelian group of rank \( m = n - g + 1 \).

A Heegaard diagram \((\Sigma, \alpha, \beta)\) consists of a Riemann surface \( \Sigma \) together with two good collections of curves \( \alpha = (\alpha_1, \ldots, \alpha_n) \) and \( \beta = (\beta_1, \ldots, \beta_n) \). (A Heegaard diagram describes a 3-manifold \( Y \); see for example \cite{22} Section 3.1.) We define a periodic domain in the Heegaard diagram \((\Sigma, \alpha, \beta)\) to be a two-chain on \( \Sigma \) that is a linear combination of the components of \( \Sigma - (\cup \alpha_i) - (\cup \beta_i) \), and with the property that its boundary is a linear combination of the alpha and beta curves. (This is a slight modification of \cite{18} Definition 2.14.) The group of periodic domains is denoted \( \Pi_{\alpha, \beta} \). Let also \( S_{\alpha, \beta} = S_\alpha + S_\beta \) be the span of all the alpha and beta curves in \( H_1(\Sigma; \mathbb{Z}) \).

Lemma 6. The group \( \Pi_{\alpha, \beta} \) of periodic domains is free Abelian of rank equal to \( 2n + 1 - \text{rank}(S_{\alpha, \beta}) \).

Proof. There is a map

\[
\psi_{\alpha, \beta} : \mathbb{Z}^{2n} \to S_{\alpha, \beta}
\]

taking the first \( n \) standard generators of \( \mathbb{Z}^{2n} \) to the classes \( [\alpha_i], i = 1, \ldots, n \), and the remaining \( n \) standard generators to the classes \( [\beta_i], i = 1, \ldots, n \). There is a short exact sequence

\[
0 \to \mathbb{Z} \to \Pi_{\alpha, \beta} \to \ker(\psi_{\alpha, \beta}) \to 0.
\]
Indeed, the map $\Pi_{\alpha,\beta} \to \ker(\psi_{\alpha,\beta})$ takes a periodic domain $D$ to the coefficients of the alpha and beta curves appearing in $\partial D$. It is surjective, and its kernel is generated by the Heegaard surface $\Sigma$ itself.

The conclusion follows immediately from the short exact sequence. \hfill \Box

Note that we can view $\Pi_\alpha$ and $\Pi_\beta$ as subgroups of $\Pi_{\alpha,\beta}$. Their intersection is generated by the two-chain $\Sigma$. Therefore,

$$\text{rank}(\Pi_\alpha + \Pi_\beta) = 2n - 1.$$  

More precisely, if we denote by $S_\alpha \oplus S_\beta \cong \mathbb{Z}^{2g}$ the exterior direct sum, there is a short exact sequence analogous to (5):

$$(6) \quad 0 \to \mathbb{Z} \to \Pi_\alpha + \Pi_\beta \to \ker(\mathbb{Z}^{2n} \to S_\alpha \oplus S_\beta) \to 0.$$  

**Corollary 7.** If $S_{\alpha,\beta} = H_1(\Sigma; \mathbb{Z})$, then $\Pi_{\alpha,\beta} = \Pi_\alpha + \Pi_\beta$.

**Proof.** The exact sequences (5) and (6) fit into a commutative diagram

$$
\begin{array}{cccccc}
0 & \to & \mathbb{Z} & \to & \Pi_\alpha + \Pi_\beta & \to & \ker(\mathbb{Z}^{2n} \to S_\alpha \oplus S_\beta) & \to & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \to & \mathbb{Z} & \to & \Pi_{\alpha,\beta} & \to & \ker(\mathbb{Z}^{2n} \to S_{\alpha,\beta}) & \to & 0
\end{array}
$$

To show that the middle vertical arrow is an isomorphism it suffices to show that the right vertical arrow is. The map $\psi_{\alpha,\beta} : \mathbb{Z}^{2n} \to S_{\alpha,\beta}$ factors through $S_\alpha \oplus S_\beta$. Consider the sequence of maps

$$\mathbb{Z}^{2g} \cong S_\alpha \oplus S_\beta \to S_{\alpha,\beta} \to H_1(\Sigma; \mathbb{Z}) \cong \mathbb{Z}^{2g}.$$  

The hypothesis says that the last inclusion is an isomorphism, which means that the composition is surjective. Since its domain and target are both $\mathbb{Z}^{2g}$, the map must be an isomorphism. This shows that $S_\alpha \oplus S_\beta \to S_{\alpha,\beta}$ is an isomorphism as well. \hfill \Box

Finally, a **triple Heegaard diagram** $(\Sigma, \alpha, \beta, \gamma)$ consists of a Riemann surface $\Sigma$ together with three good collections of curves $\alpha = (\alpha_1, \ldots, \alpha_n), \beta = (\beta_1, \ldots, \beta_n), \gamma = (\gamma_1, \ldots, \gamma_n)$. A **triply periodic domain** is then a two-chain on $\Sigma$ that is a linear combination of the components of $\Sigma - (\cup \alpha_i) - (\cup \beta_i) - (\cup \gamma_i)$, and with the property that its boundary is a linear combination of the alpha, beta, and gamma curves.

The group of triply periodic domains is denoted $\Pi_{\alpha,\beta,\gamma}$. Set $S_{\alpha,\beta,\gamma} = S_\alpha + S_\beta + S_\gamma \subset H_1(\Sigma; \mathbb{Z})$. A straightforward analog of Lemma 3 then says that $\Pi_{\alpha,\beta,\gamma}$ is a free Abelian group of rank equal to $3n + 1 - \text{rank}(S_{\alpha,\beta,\gamma})$.

### 3.2. The ungraded triangle

The following theorem was proved in [9]:

**Theorem 8.** Let $L$ be a link in $S^3$, and $L_0$ and $L_1$ the two resolutions of $L$ at a crossing, as in Figure 7. Denote by $l_0, l_1$ the number of components of the links $L_0$, and $L_1$, respectively, and set $m = \max\{l_0, l_1\}$. Then, there is an exact triangle

$$\widehat{\mathcal{HFK}}(L) \otimes V^{-m-l} \to \widehat{\mathcal{HFK}}(L_0) \otimes V^{m-l_0} \to \widehat{\mathcal{HFK}}(L_1) \otimes V^{m-l_1} \to \widehat{\mathcal{HFK}}(L) \otimes V^{m-l},$$

where $V$ denotes a two-dimensional vector space over $\mathbb{F}$.

Our goal will be to study the maps in the exact triangle behave with respect to the $\delta$-grading. In order to do this, we recall how the maps were constructed in [9].

The starting point is a special Heegaard diagram which we associate to a regular, connected, planar projection $D$ of the link $L$. (This is a suitable stabilization of the diagram...
ON THE KHOVANOV AND KNOT FLOER HOMOLOGIES OF QUASI-ALTERNATING LINKS

Figure 5. The regions near the crossing $c_0$. Since $c_0$ can be either negative or positive, we have not marked which strand is the overpass.

Figure 6. Piece of the Heegaard surface $\Sigma$ associated to a crossing $c$. It contains four (or fewer) bits of alpha curves, shown in dashed lines, and one beta curve $\beta_c$.

c onsidered in [16].) We assume that one of the crossings in $D$ is $c_0$, such that the two resolutions at $c_0$ are diagrams $D_0$ and $D_1$ for $L_0$ and $L_1$, respectively. If $D$ has $k$ crossings, then it splits the plane into $k + 2$ regions. Let $A_0, A_1, A_2, A_3$ be the regions near $c_0$ in clockwise order, as in Figure 5 and $e$ the edge separating $A_0$ from $A_1$. We can assume that $A_0$ is the unbounded region in $\mathbb{R}^2 - D$. Denote the remaining regions by $A_4, \ldots, A_{k+1}$. Let $p$ be a point on the edge $e$. If $m = \max\{l, l_0, l_1\}$ is as in the statement of Theorem 8 then we can choose $p_1, \ldots, p_{m-1}$ to be a collection of points in the plane, distinct from the crossings and such that for every component of any of the links $L, L_0$ and $L_1$, the projection of that component contains at least one of the points $p_i$ or $p$.

We denote by $\Sigma$ the boundary of a regular neighborhood of $D$ in $S^3$, a surface of genus $g = k + 1$. To every region $A_r$ ($r > 0$) we associate a curve $\alpha_r$ on $\Sigma$, following the boundary of $A_r$. To each crossing $c$ in $D$ we associate a curve $\beta_c$ on $\Sigma$ as indicated in Figure 6. In addition, we introduce an extra curve $\beta_e$ which is the meridian of the knot, supported in a neighborhood of the distinguished edge $e$. We also mark the surface $\Sigma$ with two basepoints, one on each side of $\beta_e$, as shown on the left side of Figure 7.

Furthermore, for every edge $e_i$ of $D$ containing one of the points $p_i$, $i = 1, \ldots, m-1$, we introduce a ladybug, i.e. an additional pair of alpha-beta curves on $\Sigma$, as well as an additional pair of basepoints. This type of configuration is shown on the right side of Figure 7.

The surface $\Sigma$, together with the collections of alpha curves, beta curves and basepoints, forms a multi-pointed Heegaard diagram for $S^3$ compatible with $L$, in the sense of [10, Definition 2.1]. We denote the alpha and the beta curves in the diagram by $\alpha_i, \beta_i$ with $i = 1, \ldots, n$, where $n = g + m - 1$. We reserve the index $n$ for the beta curve $\beta = \beta_n$. 
associated to the crossing $c_0$. Also, we let $\hat{\Sigma}$ denote the complement of the basepoints in the surface $\Sigma$.

We can construct similar Heegaard diagrams compatible with $L_0$ and $L_1$ as follows. The surface $\Sigma$, the alpha curves and the basepoints remain the same. However, for $L_0$ we replace the beta curves by gamma curves $\gamma_i$, $i = 1, \ldots, n$, while for $L_1$ we use delta curves $\delta_i$, $i = 1, \ldots, n$. For $i < n$, the curves $\gamma_i$ and $\delta_i$ are small isotopic translates of $\beta_i$, such that they intersect $\beta_i$ in two points, and they also intersect each other in two points. For $i = n$, we draw the curves $\gamma = \gamma_n$ and $\delta = \delta_n$ as in Figure 8; see also Figure 9 where the following intersection points are labelled:

$$\beta \cap \gamma = \{A, U\}, \gamma \cap \delta = \{B, V\}, \delta \cap \beta = \{C, W\}.$$

For the purpose of defining Floer homology, we need to ensure that the Heegaard diagrams for $L, L_0$ and $L_1$ constructed above are admissible in the sense of [22, Definition 3.5]. We achieve admissibility by stretching one tip of the alpha curve of each ladybug, and bringing it close to the basepoints associated to the distinguished edge $e$. It is easy to see that the result is admissible; see Figure 10 for an example. In that figure, to get the diagrams for
ON THE KHOVANOV AND KNOT FLOER HOMOLOGIES OF QUASI-ALTERNATING LINKS

Figure 9. A different view of Figure 8. The four gray disks correspond to the four tubes from Figure 8 and are marked accordingly.

Figure 10. A Heegaard diagram compatible with the Hopf link $L$, with $g = 3, m = 2$ and $n = 4$. The beta curves $\beta_2$ and $\beta = \beta_4$ are associated to the two crossings, $\beta_1$ to the distinguished edge, and $\beta_3$ is part of a ladybug. There are three alpha curves associated to planar bounded regions and one, $\alpha_4$, which is part of a ladybug. One tip of $\alpha_4$ is stretched to achieve admissibility.

$L_0$ and $L_1$, which are both the unknot, we replace $\beta = \beta_4$ by curves $\gamma$ and $\delta$, respectively, as in Figure 8.

Now consider the tori

$T_\alpha = \alpha_1 \times \cdots \times \alpha_n$, \quad $T_\beta = \beta_1 \times \cdots \times \beta_n$,

$T_\gamma = \gamma_1 \times \cdots \times \gamma_n$, \quad $T_\delta = \delta_1 \times \cdots \times \delta_n$,\n

which we view as totally real submanifolds of the symmetric product $\text{Sym}^n(\Sigma)$. The Floer complex $\mathcal{CF}(T_\alpha, T_\beta)$ is the vector space freely generated by the intersection points between $T_\alpha$ and $T_\beta$, and endowed with the differential

\begin{equation}
\partial x = \sum_{y \in \pi_2(T_\alpha \cap T_\beta) \{\phi \in \pi_2(x,y)\}_{|\mu(\phi)=1}} \# \left( \mathcal{M}(\phi) \right) y.
\end{equation}

Here $\pi_2(x,y)$ denotes the space of homology classes of Whitney disks connecting $x$ to $y$ in $\text{Sym}^n(\Sigma)$, $\mathcal{M}(\phi)$ denotes the moduli space of pseudo-holomorphic representatives of $\phi$ (with respect to a suitable almost complex structure as in [18]), $\mu(\phi)$ denotes its formal dimension (Maslov index), and the $\#$ sign denotes the mod 2 count of points in the (zero-dimensional) moduli space. (We will henceforth use $\mu$ to denote Maslov index, rather than the incidence number, as in Section 2.)

The homology of $\mathcal{CF}(T_\alpha, T_\beta)$ is the Floer homology $HF(T_\alpha, T_\beta)$. Up to a factor, this is the knot Floer homology of $L$:

$$HF(T_\alpha, T_\beta) \cong \widehat{HFK}(L) \otimes V^{m-l},$$

where $V$ is a two-dimensional vector space as in Theorem 8.

We can similarly take the Floer homology of $T_\alpha$ and $T_\gamma$, or $T_\alpha$ and $T_\delta$, and obtain

$$HF(T_\alpha, T_\gamma) \cong \widehat{HFK}(L_0) \otimes V^{m-l_0},
$$

$$HF(T_\alpha, T_\delta) \cong \widehat{HFK}(L_1) \otimes V^{m-l_1}.$$

Therefore, the exact triangle from Theorem 8 can be written as

\begin{equation}
HF(T_\alpha, T_\delta) \xrightarrow{(f_1)} HF(T_\alpha, T_\beta) \xrightarrow{(f_2)} HF(T_\alpha, T_\gamma) \xrightarrow{(f_3)} HF(T_\alpha, T_\delta)
\end{equation}

The maps $(f_i)_*$ ($i = 1, 2, 3$) from the triangle are all induced by chain maps $f_i$ between the corresponding Floer complexes. To define the maps $f_i$, let us first recall the definition of the usual triangle maps appearing in Floer theory. Given totally real submanifolds $T_1, T_2, T_3$ in a symplectic manifold (satisfying several technical conditions which will hold in our situations), there is a chain map

$$\mathcal{CF}(T_1, T_2) \otimes \mathcal{CF}(T_2, T_3) \to \mathcal{CF}(T_1, T_3),$$

defined by counting pseudo-holomorphic triangles. In particular, given an intersection point $z \in T_2 \cap T_3$ which is a cycle when viewed as an element of $\mathcal{CF}(T_2, T_3)$, we have a chain map

$$F_z(x) = \sum_{y \in T_3 \cap T_2} \sum_{\phi \in \pi_2(x,y)} \# (\mathcal{M}(\phi)) y.$$

Here $\pi_2(x,z,y)$ denotes the space of homology classes of triangles with edges on $T_1, T_2, T_3$ and vertices $x, z$ and $y$, respectively (in clockwise order), $\mu$ is the Maslov index, and $\# (\mathcal{M}(\phi))$ the number of their pseudo-holomorphic representatives.

Going back to our set-up, whenever we have two isotopic curves $\eta$ and $\eta'$ on the surface $\Sigma$ such that they intersect in exactly two points, we will denote by $M_{\eta \eta'} \in \eta \cap \eta'$ the top degree generator of $\mathcal{CF}(\eta, \eta')$. Given one of the intersection points in Figure 9, for example $A \in \beta \cap \gamma$, we obtain a corresponding intersection point in $T_\beta \cap T_\gamma$ by adjoining to $A$ the top degree intersection points $M_{\beta \gamma_1} \in \beta_1 \cap \gamma_1$. We denote the resulting generators by the respective lowercase letters in bold:

$$a = M_{\beta_1 \gamma_1} \times M_{\beta_2 \gamma_2} \times \cdots \times M_{\beta_n \gamma_n} \times A \in T_\beta \cap T_\gamma;
$$

$$b = M_{\gamma_1 \delta_1} \times M_{\gamma_2 \delta_2} \times \cdots \times M_{\gamma_n \delta_n} \times B \in T_\gamma \cap T_\delta;$$

respectively (in clockwise order), $\mu$ is the Maslov index, and $\# (\mathcal{M}(\phi))$ the number of their pseudo-holomorphic representatives.
\( c = M_{\delta_1\beta_1} \times M_{\delta_2\beta_2} \times \cdots \times M_{\delta_{n-1}\beta_{n-1}} \times C \in \mathbb{T}_\delta \cap \mathbb{T}_\beta; \)
\( u = M_{\beta_1\gamma_1} \times M_{\beta_2\gamma_2} \times \cdots \times M_{\beta_{n-1}\gamma_{n-1}} \times U \in \mathbb{T}_\beta \cap \mathbb{T}_\gamma; \)
\( v = M_{\gamma_1\delta_1} \times M_{\gamma_2\delta_2} \times \cdots \times M_{\gamma_{n-1}\delta_{n-1}} \times V \in \mathbb{T}_\gamma \cap \mathbb{T}_\delta; \)
\( w = M_{\delta_1\beta_1} \times M_{\delta_2\beta_2} \times \cdots \times M_{\delta_{n-1}\beta_{n-1}} \times W \in \mathbb{T}_\delta \cap \mathbb{T}_\beta. \)

The chain maps \( f_i \) giving rise to (9) are then defined to be the sums
\[
\begin{align*}
f_1 &= F_c + F_w : CF(\mathbb{T}_\alpha, \mathbb{T}_\delta) \to CF(\mathbb{T}_\alpha, \mathbb{T}_\beta); \\
f_2 &= F_a + F_u : CF(\mathbb{T}_\alpha, \mathbb{T}_\beta) \to CF(\mathbb{T}_\alpha, \mathbb{T}_\gamma); \\
f_3 &= F_b + F_v : CF(\mathbb{T}_\alpha, \mathbb{T}_\gamma) \to CF(\mathbb{T}_\alpha, \mathbb{T}_\delta). \\
\end{align*}
\]

3.3. **Periodic domains.** Let us apply the discussion in Section 3.1 to the setting of Section 3.2.

Note that \((\Sigma; \alpha, \beta)\), for example, is a Heegaard diagram for \(S^3\), hence the alpha and the beta curves span all of \(H_1(\Sigma; \mathbb{Z})\). Applying Corollary 7 we deduce that
\[
\Pi_{\alpha,\beta} = \Pi_\alpha + \Pi_\beta.
\]

Similarly, we have \(\Pi_{\alpha,\gamma} = \Pi_\alpha + \Pi_\gamma\) and \(\Pi_{\alpha,\delta} = \Pi_\alpha + \Pi_\delta\).

The situation for \(\Pi_{\beta,\gamma}\) is different. Before analyzing it, let us first understand the components of \(\Sigma - (\cup \beta_i)\), which span \(\Pi_\beta\), in detail. Their number is \(m\), which equals either \(l\) or \(l+1\), according to whether the two strands of \(L\) meeting at \(c\) are on different link components, or on the same link component. Let \(K_1, \ldots, K_l\) be the connected components of \(L\), such that \(K_i\) is the one containing the edge \(e\). If \(m = l\), then each \(K_i\) corresponds to a unique component \(D_i^\beta\) of \(\Sigma - (\cup \beta_i)\), which lies in a neighborhood of \(K_i\) (when \(\Sigma\) is viewed as the boundary of a neighborhood of \(L\)). If \(m = l + 1\), then for \(i < l\), each \(K_i\) corresponds again to some \(D_i^\beta\), but in the neighborhood of \(K_l\) there are now two components of \(\Sigma - (\cup \beta_i)\), which we denote by \(D_i^\beta\) and \(D_{i+1}^\beta\), such that \(D_i^\beta\) is the one whose boundary contains the curve \(\beta = \beta_n\).

Note that, regardless of whether \(m = l\) or \(m = l+1\), the component \(D_i^\beta\) contains the curve \(\beta_n\) with multiplicity \(\pm 1\) (see Figure 11). This means that the class \([\beta_n] \in S_\beta \subset H_1(\Sigma; \mathbb{Z})\) is in the span of the other beta curves. In other words,
\[
S_\beta = \text{Span} (\beta_1, \ldots, \beta_{n-1}).
\]

Similar remarks apply to \(\Sigma - (\cup \gamma_i)\) and \(\Sigma - (\cup \delta_i)\). Their components are denoted \(D_i^\gamma\) and \(D_i^\delta\), respectively, for \(i = 1, \ldots, m\). Recall that for each \(i = 1, \ldots, n-1\), the curves \(\beta_i, \gamma_i\) and \(\delta_i\) are isotopic. Therefore, Equation (10), together with its analogs for the beta and gamma curves, implies that
\[
S_\beta = S_\gamma = S_\delta.
\]

For each \(j = 1, \ldots, n-1\), the curves \(\beta_j\) and \(\gamma_j\) are separated by two thin bigons in \(\Sigma\). The difference of these bigons is a periodic domain \(D_j^{\beta,\gamma}\), with boundary \(\beta_j - \gamma_j\). Equation (11) implies that \(\text{rank}(S_{\beta,\gamma}) = \text{rank}(S_\beta) = g\), so from Lemma 8 we deduce that \(\text{rank}(\Pi_{\beta,\gamma}) = 2n + 1 - g = n + m\). In fact, it is not hard to check that the following is true:

**Lemma 9.** The domains \(D_i^\beta, D_i^\gamma\) \((i = 1, \ldots, m)\) and \(D_j^{\beta,\gamma}\) \((j = 1, \ldots, n-1)\) span the group \(\Pi_{\beta,\gamma}\).
Figure 11. We illustrate here Equation (10). The component $D_\beta$, which gives a homological relation between $\beta_n$ and other $\beta$-curves, is shaded. There are two cases: when $m = \ell$, the region labelled here by 5 is included in $D_\beta$. Otherwise, when $m = \ell + 1$, $D_\beta$ terminates in a different meridional $\beta$-circle. In either case, the boundary of $D_\beta$ consists of $\beta$-circles, and it contains $\beta_n$ with multiplicity one.

Note that we gave a set of $2m + n - 1$ generators for the group $\Pi_{\beta,\gamma}$ of rank $n + m$. There are indeed $m - 1$ independent relations between these generators, namely for each of the $m - 1$ components $K_i$ of $L$ (or $L_0$) not containing either of the strands intersecting at $c$, the difference $D_\beta^i - D_\gamma^i$ can also be written as a sum of some domains $D_{j,\gamma}$ (corresponding to the crossings on $K_i$).

Next, let us look at the triply periodic domains with boundary on the alpha, beta, and gamma curves.

Lemma 10. We have $\Pi_{\alpha,\beta,\gamma} = \Pi_\alpha + \Pi_{\beta,\gamma}$.

Proof. Let $D$ be any triply periodic domain in $\Pi_{\alpha,\beta,\gamma}$. If the curve $\gamma_n$ appears (with nonzero multiplicity) in the boundary of $D$, by the analog of [10] for gamma curves we can subtract some domain in $\Pi_{\beta,\gamma} \subset \Pi_{\beta,\gamma}$ from $D$ and obtain a new domain, in which the multiple of $\gamma_n$ from $\partial D$ was traded for a combination of the other gamma curves $\gamma_1, \ldots, \gamma_{n-1}$. Next, whenever we have some curve $\gamma_j$ in the boundary ($j < n$), we can add the corresponding domain $D_{j,\gamma} \subset \Pi_{\beta,\gamma}$ to trade it for a beta curve. Thus we arrive at a domain in $\Pi_{\alpha,\beta}$ and the conclusion follows from Equation (9).

Note that Lemma 9 has straightforward analogs about the structure of the groups $\Pi_{\gamma,\delta}$ and $\Pi_{\delta,\beta}$. Similarly, Lemma 10 has straightforward analogs about the structure of the groups $\Pi_{\alpha,\gamma,\delta}$ and $\Pi_{\alpha,\delta,\beta}$.

3.4. **The relative $\delta$-grading.** Pick $\mathbf{x}, \mathbf{y} \in T_\alpha \cap T_\beta$. Let $\pi_2(\mathbf{x}, \mathbf{y})$ be the space of homology classes of Whitney disks in $\text{Sym}^n(\Sigma)$ connecting $\mathbf{x}$ and $\mathbf{y}$. (Recall that $\hat{\pi}_2(\mathbf{x}, \mathbf{y})$ is the corresponding space in $\text{Sym}^n(\hat{\Sigma})$.) Since $(\Sigma, \alpha_1, \ldots, \alpha_n, \beta_1, \ldots, \beta_n)$ is a Heegaard diagram for $S^3$, we have $\pi_2(\mathbf{x}, \mathbf{y}) \neq \emptyset$ for any $\mathbf{x}$ and $\mathbf{y}$. Note that $\pi_2(\mathbf{x}, \mathbf{x})$ can be identified with the group of periodic domains $\Pi_{\alpha,\beta}$. 
Every class \( \phi \in \pi_2(x, y) \) has a Maslov index \( \mu(\phi) \in \mathbb{Z} \). In the usual construction of knot Floer homology, the extra basepoints on the Heegaard surface \( \Sigma \) are of two types: half of them are denoted \( w_j \) and the other half \( z_j \), with \( j = 1, \ldots, m+1 \), such that every connected component of \( \Sigma - \cup \alpha_i \) or \( \Sigma - \cup \beta_i \) contains exactly one of the \( w_j \) and one of the \( z_k \). Let \( W(\phi) \) and \( Z(\phi) \) be the intersection numbers of \( \phi \) with the union of all \( \{ w_j \} \times \text{Sym}^{n-1}(\Sigma) \) and the union of all \( \{ z_j \} \times \text{Sym}^{n-1}(\Sigma) \), respectively. Thus \( \pi_2(x, y) \) is the space of classes \( \phi \) with \( W(\phi) = Z(\phi) = 0 \).

The difference in the Maslov grading \( H \) (denoted \( i \) in the introduction) between \( x \) and \( y \) can be calculated by picking some \( \phi \in \pi_2(x, y) \) and applying the formula

\[
H(x) - H(y) = \mu(\phi) - 2W(\phi).
\]

Similarly, the difference in the Alexander grading \( A \) (denoted \( j \) in the introduction) is

\[
A(x) - A(y) = Z(\phi) - W(\phi).
\]

Setting \( P(\phi) = Z(\phi) + W(\phi) \), the difference in the grading \( \delta = A - H \) is then

\[
\delta(x) - \delta(y) = P(\phi) - \mu(\phi).
\]

Therefore, if we limit ourselves to considering the \( \delta \) grading, there is no difference between the two types of basepoints. This explains why we have not distinguished between them in Section 3.2 and we will not distinguish between them from now on either.

Observe that the relative \( \delta \) grading is well-defined, i.e. we have \( \mu(\phi) - P(\phi) = \mu(\phi') - P(\phi') \) for any \( \phi, \phi' \in \pi_2(x, y) \). Indeed, because \( \mu \) and \( P \) are additive under concatenation, it suffices to prove that \( \mu(\phi) - P(\phi) = 0 \) for any \( \phi \in \pi_2(x, x) = \Pi_{\alpha, \beta} \). By Equation (9), the group \( \Pi_{\alpha, \beta} \) is generated by the connected components of \( \Sigma - \cup \alpha_i \) and \( \Sigma - \cup \beta_i \). Each such component has \( \mu(\phi) = P(\phi) = 2 \), so the relative \( \delta \) grading is well-defined.

Lemma 11. The chain maps \( f_1, f_2, f_3 \) that induce the triangle \( \square \) preserve the relative \( \delta \) grading.

Proof. First, observe that a triangle map such as \( F_a : CF(T_\alpha, T_\beta) \to CF(T_\alpha, T_\gamma) \) preserves the relative \( \delta \) grading. In other words, we need to show that adding a triply periodic domain \( D \in \Pi_{\alpha, \beta, \gamma} \) to a class \( \phi \in \pi_2(x, a, y) \) does not change the quantity \( \mu(\phi) - P(\phi) \). By Lemmas 9 and 10, it suffices to show that the classes of the domains \( D_1^\alpha, D_1^\beta, D_1^\gamma \) and \( D_j^\beta, \gamma \) all have \( \mu = P \). Indeed, for \( D_1^\alpha, D_1^\beta, D_1^\gamma \) this is the argument in the paragraph before Lemma 11, while for each \( D_j^\beta, \gamma \) (\( j = 1, \ldots, n-1 \)) we have \( \phi = P = 0 \).

Next, in order to show that \( f_2 = F_a + F_u \) preserves the relative \( \delta \)-grading, we exhibit a class \( \phi \in \pi_2(a, u) \) with \( \mu(\phi) = P(\phi) \). In Figure 9 there is a bigon relating \( A \) and \( U \) which is connected by the tube numbered 2 to the rest of the Heegaard diagram. This bigon is also shown on the left in Figure 12. Following the tube, we encounter several disks (or possibly none) bounded by beta circles as in the middle of Figure 12 until we find a disk as on the right of Figure 12. Lipschitz’s formula for the Maslov index \( \phi \) says that \( \mu(\phi) \) can be computed as the sum of the Euler measure \( e(\phi) \) and a vertex multiplicity \( n(\phi) \). (We refer to \( \phi \) for the definitions.) The punctured bigon on the left of Figure 12 contributes \(-\frac{1}{2}\) to \( e(\phi) \) and \( \frac{1}{2} \) to \( n(\phi) \), each middle disk \(-1\) to \( e(\phi) \) and \( 1 \) to \( n(\phi) \), and the disk on the right \( 0 \) to \( e(\phi) \) and \( 1 \) to \( n(\phi) \). Thus \( \mu(\phi) = P(\phi) = 1 \).

The arguments for \( f_1 \) and \( f_3 \) are similar.

3.5. The absolute \( \delta \)-grading. The generators \( x \in T_\alpha \cap T_\beta \) are of two kinds. They all consist of \( n \)-tuples of points in \( \Sigma \), one on each alpha curve and on each beta curve. If for each ladybug (consisting of a pair of curves \( \alpha_i \) and \( \beta_i \), \( x \) contains one of the two points
in $\alpha_i \cap \beta_i$, we call the generator $x$ Kauffman. Otherwise, it is called non-Kauffman. Note that, if we hadn’t had to stretch the alpha curves on the ladybugs to achieve admissibility, all generators would have been Kauffman.

Every $x \in \mathbb{T}_\alpha \cap \mathbb{T}_\beta$ has an absolute $\delta$-grading $\delta(x) \in \frac{1}{2}\mathbb{Z}$. We will explain now a simple formula for $\delta(x)$ when $x$ is Kauffman.

Consider the regions $A_0, A_1, A_2, \ldots, A_{k+1}$ as in the second paragraph after the statement of Theorem 8. Each of the $k$ crossings in $D$ is on the boundary of four regions. A state, cf. [4], is an assignment which associates to each crossing one of the four incoming quadrants, such that the quadrants associated to distinct vertices are in distinct regions, and none are corners of the regions $A_0$ or $A_1$.

One can associate a monomial to each state such that as we sum all these monomials we obtain the Alexander polynomial of the link $L$, [4]. Therefore, if the Alexander polynomial $\Delta_L(q)$ is nonzero (or, in particular, if $\Delta_L(-1) = \det(L) \neq 0$), then there must be at least one state.

To each Kauffman generator $x$ we can associate a state in a natural way: at each crossing $c$ the corresponding beta curve intersects exactly one of the alpha curves of the neighboring regions in a point of $x$, and the quadrant in that region is the one we associate to $c$. In [10], the Maslov and Alexander gradings of Kauffman generators are calculated in terms of their states; compare also [14].

For our purposes, it suffices to know how to compute the $\delta$-grading. If $x$ is Kauffman and $c$ is a crossing in $D$, we let $\delta(x,c) \in \{0, \pm 1/2\}$ be the quantity from Figure 13, chosen according to which quadrant at $c$ appears in the state of $x$. Then:

$$\delta(x) = \sum_c \delta(x,c).$$
A similar discussion applies to the diagrams $D_0$ and $D_1$ of the resolutions $L_0$ and $L_1$, respectively, except that in those cases there is no contribution from the resolved crossing $c_0$.

Note that the $\delta$-grading of a Kauffman generator $\mathbf{x}$ does not depend on which of the two intersection points between the two curves of a ladybug appears in $\mathbf{x}$.

**Lemma 12.** Suppose that $c_0$ is a positive crossing in $D$ (so that $L_0$ is the oriented resolution $L_v$) and that $\det(L_0) \neq 0$. Then the map $f_2 : CF(T_\alpha, T_\beta) \to CF(T_\alpha, T_\gamma)$ decreases $\delta$-grading by $1/2$.

**Proof.** By Lemma 11 we already know that $f_2$ preserves the relative $\delta$-grading. Thus, it suffices to exhibit two generators $\mathbf{x} \in T_\alpha \cap T_\beta$ and $\mathbf{y} \in T_\alpha \cap T_\gamma$ with $\delta(\mathbf{x}) - \delta(\mathbf{y}) = 1/2$, and such that there exists a holomorphic triangle of index zero in $\hat{\pi}_2(\mathbf{x}, \mathbf{a}, \mathbf{y})$.

Since $\det(L_0) \neq 0$, the diagram $D_0$ has at least one Kauffman generator $\mathbf{y}$. There is a corresponding Kauffman generator $\mathbf{x} \in T_\alpha \cap T_\beta$, such that each $y_i \in \gamma_i \cap \mathbf{y}$, $(i < n)$ is close to some $x_i \in \beta_i \cap \mathbf{x}$ (they are related by the isotopy between $\gamma_i$ and $\beta_i$), while $x_n \in \beta \cap \mathbf{x}$ and $y_n \in \gamma \cap \mathbf{y}$ are two vertices of the shaded triangle in Figure 8 with the third vertex at $A$. That shaded triangle, coupled with the small triangles with vertices at $x_i, y_i$, and $M_{\delta_i, \gamma_i}$ for $i = 1, \ldots, n - 1$, gives the desired holomorphic triangle in $\text{Sym}^{\alpha}(\hat{\Sigma})$. To check that $\delta(\mathbf{x}) - \delta(\mathbf{y}) = 1/2$, note that in formula (12) the contributions to $\delta(\mathbf{x})$ and $\delta(\mathbf{y})$ from each crossing are the same, except that there is an extra contribution of $1/2$ to $\delta(\mathbf{x})$ coming from $c_0$. 

**Lemma 13.** Suppose that $c_0$ is a positive crossing in $D$ (so that $L_1$ is the unoriented resolution $L_u$) and that $\det(L_1) \neq 0$. Then the map $f_1 : CF(T_\alpha, T_\delta) \to CF(T_\alpha, T_\beta)$ shifts $\delta$-grading by $e/2$, where $e$ is as in the statement of Lemma 8.

**Proof.** By Lemma 11 we already know that $f_1$ preserves the relative $\delta$-grading. Again, it suffices to exhibit two generators $\mathbf{x} \in T_\alpha \cap T_\beta$ and $\mathbf{y} \in T_\alpha \cap T_\delta$ with $\delta(\mathbf{x}) - \delta(\mathbf{y}) = e/2$, and such that there exists a holomorphic triangle of index zero in $\hat{\pi}_2(\mathbf{y}, \mathbf{w}, \mathbf{x})$.

Since $\det(L_1) \neq 0$, we can pick a Kauffman generator $\mathbf{y} \in T_\alpha \cap T_\delta$. As in the proof of Lemma 12, there is a corresponding Kauffman generator $\mathbf{x} \in T_\alpha \cap T_\beta$ and a holomorphic triangle of index zero as desired, consisting of $n - 1$ small triangles with one vertex at $M_{\delta_i, \beta_i}$ for $i = 1, \ldots, n - 1$, and the shaded triangle in Figure 8 with one vertex at $W$.

To check that $\delta(\mathbf{x}) - \delta(\mathbf{y}) = e/2$, let $n_+$ be the number of positive crossings in $D$ (excluding $c_0$) which change sign in $D_1$. At each such crossing $c$, we have:

$$\delta(\mathbf{x}, c) = \delta(\mathbf{y}, c) + 1/2.$$

Let also $n_-$ be the number of negative crossings in $D$ which change sign in $D_1$. At each such crossing $c$, we have:

$$\delta(\mathbf{x}, c) = \delta(\mathbf{y}, c) - 1/2.$$

Therefore,

$$\delta(\mathbf{x}) - \delta(\mathbf{y}) = (n_+ - n_-)/2 = e/2.$$

**Proposition 14.** Let $L$ be a link and $L_0, L_1$ its two resolutions at a crossing as in Figure 7. Assume that $\det(L_0), \det(L_1) > 0$ and $\det(L) = \det(L_0) + \det(L_1)$. Then, two of the three maps in the exact triangle from Theorem 5 behave as follows with respect to the $\delta$-grading:

$$\widetilde{HF}_{s-\sigma(L_1)/2}(L_1) \otimes V^{m-l_1} \to \widetilde{HF}_{s-\sigma(L_0)}(L_0) \otimes V^{m-l_0} \to \widetilde{HF}_{s-\sigma(L_0)}(L_0) \otimes V^{m-l},$$

where $V$ denotes a two-dimensional vector space over $\mathbb{F}$, in grading zero.
Proof. When the given crossing in $L$ is positive, this follows from (8), together with the results of Lemmas 3, 12, and 13. The case when the crossing is negative is similar. □

Proof of Theorem 2. Using Proposition 14, we can argue in the same way as in the proof of Theorem 1. Note that we do not have to know the change in the absolute $\delta$-grading under the third map $(f_3)_* : HF(T_\alpha, T_\beta) \rightarrow HF(T_\gamma, T_\delta)$ in the exact triangle. Indeed, recall that the Euler characteristic of $\hat{HFK}$ is (up to a factor) the Alexander polynomial, which evaluated at $-1$ gives the determinant of the link. If we know that $L_0$ and $L_1$ are Floer homologically $\sigma$-thin and we want to show the same for $L$, the fact that $\det(L) = \det(L_0) + \det(L_1)$ together with the ungraded triangle implies that

$$\text{rank } (\hat{HFK}(L) \otimes V^{m-l}) = \text{rank } (\hat{HFK}(L_0) \otimes V^{m-l_0}) + \text{rank } (\hat{HFK}(L_1) \otimes V^{m-l_1}).$$

Hence $(f_3)_* = 0$, and the inductive step goes through. □
