(Dated: 5 March 2011)

We consider the average distance between four bases in dimension six. The distance between two orthonormal bases vanishes when the bases are the same, and the distance reaches its maximal value of unity when the bases are unbiased. We perform a numerical search for the maximum average distance and find it to be strictly smaller than unity. This is strong evidence that no four mutually unbiased bases exist in dimension six. We also provide a two-parameter family of three bases which, together with the canonical basis, reach the numerically-found maximum of the average distance, and we conduct a detailed study of the structure of the extremal set of bases.

I. INTRODUCTION

Two orthonormal bases of a Hilbert space are said to be unbiased if the transition probability from any state of the first basis to any state of the second basis is independent of the two chosen states. In the finite dimensional case of \( \mathbb{C}^d \), the normalization of the two basis states \( |a_i\rangle \) and \( |b_j\rangle \) of two unbiased bases implies the defining property

\[
|\langle a_i|b_j \rangle|^2 = \frac{1}{d} \quad \text{for all } i, j = 1, 2, \ldots, d. \quad (1)
\]

This maximum degree of incompatibility between two bases \( [1, 2] \) states that the corresponding nondegenerate observables are complementary. Indeed, the technical formulation of Bohr’s Principle of Complementarity \( [3] \) that is given in Ref. \( [4] \) relies on the unbiasedness of the pair of bases. Textbook discussions of this matter can be found in Refs. \( [3, 4, 7] \), and Ref. \( [7] \) is a recent review on mutually unbiased bases (MUB), which are sets of bases that are pairwise unbiased.

In addition to playing a central role in quantum kinematics, we note that MUB are important for quantum state tomography \( [8, 9] \), for quantifying wave-particle duality in multi-path interferometers \( [10] \), and for various tasks in the area of quantum information, such as quantum key distribution \( [11] \) or quantum teleportation and dense coding \( [12, 13] \). In the context of quantum state tomography, \( d+1 \) von Neumann measurements provide \( d-1 \) independent data each in the form of \( d \) probabilities with sum unit, so that in total one has the required \( d^2 - 1 \) real numbers that characterize the quantum state. A set of \( d+1 \) MUB is optimal, in a certain sense \( [8] \), for these measurements—if there is such a set. Such a set is termed maximal; there cannot be more than \( d+1 \) MUB, since there are at most \( d+1 \) \((d-1)\)-dimensional orthogonal subspaces in a \((d^2-1)\)-dimensional real vector space \( \mathbb{R}^{d^2-1} \).

Ivanovic \( [8] \) gave the first construction of maximal sets of MUB if the dimension \( d \) is a prime, and Wootters and Fields \( [9] \) succeeded in constructing maximal sets when \( d \) is the power of a prime. These two cases have been rederived in various ways; see Refs. \( [10, 17] \), for example. For other finite values of \( d \), maximal sets of MUB are unknown, but it is always possible to have at least three MUB (see \( [7] \) and references therein).

The smallest non-prime-power dimension is \( d = 6 \). Little is known for sure about the six-dimensional case, for which Zauner has conjectured that no more than three MUB exist \( [18] \). Numerical studies seem to support Zauner’s conjecture \( [19, 20] \). Computer-aided analytical methods, like Gröbner bases or SemiDefinite Programming, have also been applied to this problem \( [21] \), but limitations in computational power have so far prevented any definitive answer.

Recently, Bengtsson et al. \( [22] \) introduced a distance between two bases for a quantification of the notion of “unbiasedness.” The distance vanishes when the two bases are identical and attains its maximal value of unity when they are unbiased. One can then consider the average squared distance (ASD) between several bases and search for its maximal value. Importantly, this ASD is unity if the bases are pairwise unbiased, and only then. A numerical search for the maximum of the ASD between four bases in dimension six can be performed. Actually, a numerical study on essentially the same quantity was recently carried out by Butterley and Hall \( [23] \). In terms of the ASD, they found the surprisingly large but strictly-less-than-one maximal value of 0.9983. This is strong evidence that no more than three MUB exist in dimension six. However, the set of bases behind this maximum value is not reported in Ref. \( [23] \).

It is the objective of the present paper to close this gap. In Sec. \( III \) we review the notion of Bengtsson et al. for the distance between bases. We perform a numerical search for the maximum ASD between four bases in dimension six and report, in Sec. \( III \) our results which confirm the maximum found by Butterley and Hall. We then provide a two-parameter family of three bases which, together with the canonical basis, reaches the numerically-found maximum, for which we give a closed expression. We study this family in detail in Sec. \( IV \) and conclude with a summary and outlook. Some matters of a technical nature are reported in the Appendix.
II. A DISTANCE BETWEEN BASES

The main goal of this paper is twofold. First we numerically search for the maximum value of the ASD between four bases in dimension six and see that we cannot obtain four MUB. And second, we provide a two-parameter family of three bases which, together with the canonical basis, reaches the numerically-found maximum.

Following Bengtsson et al. [22], we consider two orthonormal bases of kets of $\mathbb{C}^d$, $a = \{a_i\}$ and $b = \{b_j\}$, and quantify their squared distance by

$$D_{ab}^2 = 1 - \frac{1}{d} \sum_{i,j=1}^{d} \left( |\langle a_i | b_j \rangle|^2 - \frac{1}{d} \right)^2,$$

$$= \frac{1}{d-1} \sum_{i,j=1}^{d} |\langle a_i | b_j \rangle|^2 \left( 1 - |\langle a_i | b_j \rangle|^2 \right).$$

(2)

Clearly, this distance is symmetrical, $D_{ab} = D_{ba}$ and vanishes when the bases are the same, that is: when the two sets of projectors $\{a_i\} \{a_i\}$ and $\{b_j\} \{b_j\}$ are identical; the maximal distance is unity, $D_{ab} \leq 1$; and this maximum is reached if the bases are unbiased, $|\langle a_i | b_j \rangle|^2 = 1/d$, and only then.

In the original reasoning by Bengtsson et al., $D_{ab}$ is actually the chordal Grassmanian distance of two planes in the $(d^2 - 1)$-dimensional real vector space associated with traceless hermitian operators in the $d$-dimensional complex Hilbert space. One can also view $D_{ab}$ as the Hilbert-Schmidt distance between two rank-$d$ statistical operators in $\mathbb{C}^d \otimes \mathbb{C}^d$ that are in one-to-one correspondence with the $d$-dimensional bases. Consult Appendix A for this matter.

For a set of $k$ bases, we have the ASD between the $(k(k-1)/2)$ pairs of bases, given by

$$\overline{D}^2 = \frac{2}{k(k-1)} \sum_{a<b=1}^{k} D_{ab}^2.$$  

(3)

Owing to the normalization, we have $\overline{D}^2 \leq 1$ with $\overline{D}^2 = 1$ only if the $k$ bases are pairwise unbiased.

With this notion of distance at hand, we can numerically search for the maximum ASD between four bases in dimension six and see whether we obtain $\overline{D}^2 = 1$, or in other words, if we can find four MUB. This search is the subject matter of the next section.

III. NUMERICAL STUDY

Our numerical approach relies on the mapping between 1-qudit operators and 2-qudit states established in Chapter 3 of [3]. Plus we use the steepest-ascent algorithm to find the maximum ASD between four bases in dimension six. Details of the numerical method are presented in Appendix A. Our numerical results are reported below. 

TABLE 1: Rate of success and CPU time (in seconds) for the steepest-ascent search for the maximum ASD. The absolute maximum of $\overline{D}^2 = 1$ is always reached for $d = 2$, 3, 4, 5. As the seven-dimensional case also illustrates, the difficulty of finding the global maximum increases rapidly with the dimension because there are many local maxima at which the steepest-ascent search can get stuck. We have also looked for the largest ASD between four bases in dimensions two to seven. We could not find four MUB in dimensions two and six. The CPU time refers to a Intel®Core™2 Duo CPU E6550 processor at 2.33 GHz, supported by 3.25 GB of RAM.

| d | $\overline{D}_{\text{max}}$ | Success rate (%) | CPU time | $\overline{D}_{\text{max}}$ | Success rate (%) | CPU time |
|---|---|---|---|---|---|---|
| 2 | 1  | 100  | 0.409 | 8/9 | 100  | 0.108 |
| 3 | 1  | 99.9 | 0.272 | 1   | 99.9 | 0.272 |
| 4 | 1  | 100  | 1.268 | 1   | 100  | 0.976 |
| 5 | 1  | 99.7 | 4.432 | 1   | 59.8 | 10.995 |
| 6 | 0.9849 | 39.2 | 188.407 | 0.9983 | 69.6 | 20.158 |
| 7 | 1  | 3.8  | 467.157 | 1   | 1.1  | 101.002 |

A similar numerical study was recently performed by Butterley and Hall [23] who minimized $1 - \overline{D}^2$ with the so-called Levenberg-Marquadt algorithm. Our approach confirms the extremal value they found, and we also exhibit the structure of the four bases that maximize $\overline{D}^2$ for $d = 6$.

We have used our code not only in dimension $d = 6$ but also for other $d$ values as a mean of benchmarking. We have run our code 2,500 times for the dimensions two to five, 10,000 times for the dimension six and 300 times for the dimension seven, both for $d = d + 1$ bases and for four bases. Our results are summarized in Table 1.

Only in two cases, the maximum ASD does not reach the upper bound of $\overline{D}^2 = 1$. They are the cases of four bases in dimension two and six.

At most three MUB can be constructed in dimension two. Thus the maximum ASD between four bases has to be less than one. This example is interesting because it can be analytically solved. In $\mathbb{R}^3$, the four bases correspond to the tetrahedron, where each edge represents a basis.

Importantly, we have searched for the maximum ASD between four bases in dimension six. We have found the largest value to be $\overline{D}_{\text{max}} = 0.9983$. In the search for the global maximum, we have also found a few other local maxima whose frequencies of occurrence are reported in Figure 1. These results are consistent with those reported by Butterley and Hall [23]. We find the same local and global maxima with very similar frequencies. This is as expected because we have generated the four random bases from which the search proceeds in the same way as Butterley and Hall, using the same dedicated Matlab command. The two numerical methods are different, however. We use the steepest-ascent algorithm
We study in detail the properties of this family and show that, for some definite values of the two parameters, these three bases together with the canonical basis reach the numerically-found maximum ASD of 0.9983. This definite structure of the optimal four bases is our main result, with a closed expression for $D_{2 \text{max}}^2$ as a most-welcome bonus; see Eq. (22) below.

Harking back to Table 1 we note that the best set of seven bases in dimension six has an ASD of 0.9849, short of unity by a mere one-and-a-half percent. For all practical purposes—those of state tomography, say—these seven bases are marginally worse than the imaginary seven MUB that no one has managed to find.

### IV. THE TWO-PARAMETER FAMILY

Following Karlsson [23], we express the two-parameter family in terms of $2 \times 2$ block matrices where each of the nine blocks is itself a complex Hadamard matrix. Such $2 \times 2$ block matrices are called $H_2$-reducible. The two-parameter family contains three bases, the fourth basis being the canonical basis. We will see that these three Hadamard bases are equidistant, that their determinants are identical, and that they belong to the so-called Fourier transposed family $F_0^T$. Finally, we will show that together with the canonical basis they reach the numerically-found maximum of the ASD.

#### A. Parametrization

We begin by defining a few quantities. We will need the third root of unity $\omega = \exp(i2\pi/3)$ as well as the following $2 \times 2$ matrices:

$$Z = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad X = \begin{bmatrix} x^* & 0 \\ 0 & x \end{bmatrix}, \quad F_2 = \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix}$$

and

$$T = \begin{bmatrix} 1 & \omega t^2 \\ \omega^* t^2 & 1 \end{bmatrix}$$

(5)

where $t = \exp(i\theta_1)$ and $x = \exp(i\theta_2)$ are two phases. Let us notice that $T$ and $F_2$ are themselves Hadamard matrices.

The Hadamard matrices for the three bases are given by

$$M_1 = \frac{1}{\sqrt{6}} X_1 N_1,$$

$$M_2 = \frac{1}{\sqrt{6}} \begin{bmatrix} F_2 & F_2 & F_2 \\ T & \omega T & \omega^* T \\ T & \omega^* T & \omega T \end{bmatrix} = \frac{1}{\sqrt{6}} N_2,$$

where $F_2$ and $T$ are $2 \times 2$ matrices.
and
\[
M_3 = \begin{bmatrix} X^* & 0 & 0 \\ 0 & \omega X^* & 0 \\ 0 & 0 & -itX^2 \end{bmatrix} \frac{1}{\sqrt{6}} \begin{bmatrix} F_2 & F_2 & F_2 \\ T & \omega T & \omega^* T \\ F_2 & \omega F_2 & \omega F_2 \end{bmatrix}
\]
\[= \frac{1}{\sqrt{6}}X_3N_3. \quad (6)\]

In the above parameterization, we have introduced the matrices \(X_i\) and \(N_i, i = 1, 2, 3\), which we will address as dephasing and central matrices, respectively. The derivation of this parameterization is explained in Appendix B.

The next section is devoted to proving the three properties earlier mentioned. Before we turn to the proofs, we wish to point out that an additional relation between all the fundamental properties of the two-parameter family of this parameterization is explained in Appendix B.

B. Properties

1. Equidistance

A significant property of the three proposed Hadamard matrices is their equidistance. The relevant terms that appear in the distance between the two bases \(M_a\) and \(M_b\) (i.e., \(|\langle a_i|b_j\rangle|\)) are the elements of the product matrix \(M_a^\dagger M_b\) (i.e., \(|\langle a_i|b_j\rangle|\)) in absolute value. Therefore, if the three product matrices \(M_1^\dagger M_2\), \(M_2^\dagger M_3\) and \(M_3^\dagger M_1\) have equal coefficients in absolute value, then the three bases \(M_1, M_2\) and \(M_3\) are equidistant. This is exactly what happens here. Indeed, we have the following cyclic structure:

\[
M_1^\dagger M_2 = \frac{1}{6} \begin{bmatrix} a_1 & a_2 & a_3 \\ a_3 & a_1 & a_2 \\ a_2 & a_3 & a_1 \end{bmatrix}, \quad M_2^\dagger M_3 = \frac{1}{6} \begin{bmatrix} b_1 & b_2 & b_3 \\ b_3 & b_1 & b_2 \\ b_2 & b_3 & b_1 \end{bmatrix},
\]

and

\[
M_3^\dagger M_1 = \frac{1}{6} \begin{bmatrix} c_1 & c_2 & c_3 \\ c_3 & c_1 & c_2 \\ c_2 & c_3 & c_1 \end{bmatrix} \quad (8)
\]

where, on the one hand, the \(2 \times 2\) submatrices \(a_1, b_2\) and \(c_3\) have the same coefficients in absolute value and, on the other hand, \(a_2, a_3, b_1, b_3, c_1\) and \(c_2\) have the same coefficients in absolute value. More precisely, these matrices have the following forms (where the symbol \(\cdot\) stands for swapping the two diagonal elements). First,

\[
a_1 = \begin{bmatrix} \alpha & \beta \\ -\beta^* & \alpha^* \end{bmatrix}, \quad b_2 = \tilde{a}_1,
\]

and

\[
c_3 = \begin{bmatrix} i\omega t^* \beta & i\omega t^* \alpha \\ i\omega t^* \alpha^* & i\omega t^* \beta \end{bmatrix} \quad (9)
\]

Second,

\[
a_2 = \begin{bmatrix} \gamma & \delta \\ \epsilon \omega^* \gamma^* \\ -\delta^* \gamma^* \end{bmatrix}, \quad b_1 = \tilde{a}_2,
\]

\[
a_3 = \begin{bmatrix} \omega \gamma & -\epsilon^* \\ -\delta^* \gamma^* \\ \omega^* \gamma^* \end{bmatrix}, \quad b_3 = \tilde{a}_3,
\]

\[
c_1 = \begin{bmatrix} it^* \delta & i\omega t \gamma \\ i\omega^* t \gamma^* -i\omega^* t \epsilon^* \end{bmatrix}, \quad c_2 = \tilde{c}_1. \quad (10)
\]

The various coefficients in Eqs. (9) and (10) can be expressed in terms of the two angles \(\theta_x\) and \(\theta_t\),

\[
\alpha = 4 \cos(\theta_x) \left(1 - \omega t^* \sin(\theta_x)\right),
\]

\[
\beta = -2\omega^* t \left(\cos(2\theta_x) - 2 \cos(\theta_t - 2\pi/3) \sin(\theta_x)\right),
\]

\[
\gamma = -2\omega^* \cos(\theta_x) \left(\omega^* + 2t^* \sin(\theta_x)\right),
\]

\[
\delta = -2it \left(\cos(2\theta_x) - 2 \cos(\theta_t) \sin(\theta_x)\right),
\]

\[
\epsilon = -2i\omega^* t^* \left(\cos(2\theta_x) - 2 \cos(\theta_t + 2\pi/3) \sin(\theta_x)\right).
\]

When Eq. (4) is fulfilled, we have \(\epsilon = \omega^* \delta^*\) and a few simplifications arise. We obtain

\[
a_3 = \omega Z a_2 Z, \quad b_3 = \omega Z b_1 Z, \quad \text{and} \quad c_2 = -Z c_1 Z \quad (12)
\]

for example.

2. Determinant

A direct calculation shows that

\[
\text{Det}(X_1) = \text{Det}(N_1) = \text{Det}(X_3) = \text{Det}(N_3) = w t^2. \quad (13)
\]

Accordingly, the three Hadamard bases share the same determinant

\[
\text{Det}(M_1) = \text{Det}(M_2) = \text{Det}(M_3) = w^* t^4. \quad (14)
\]

However, although the determinants are equal, there seems to be no simple relation between the three matrices \(M_1, M_2,\) and \(M_3\). In particular, they do not have the same spectrum and are, therefore, not related by unitary operators.

3. Fourier transposed family

The Fourier transposed family, first studied by Haagerup [26], is parameterized by Karlsson in the
form \[25\]

\[
F_0^T \sim \begin{bmatrix} F_2 & F_2 & F_2 \\ T_1 \omega T_1 & \omega^* T_1 \\ T_2 \omega^* T_2 & \omega T_2 \end{bmatrix},
\]

(15)

where the \(2 \times 2\) Hadamard matrices \(T_1\) and \(T_2\) are given by

\[
T_i = \begin{bmatrix} 1 & t_i \\ 1 & -t_i \end{bmatrix}, \quad |t_i| = 1.
\]

(16)

The equivalence relation in Eq. (15) means equality up to left and right dephasing and left and right permutations. In other words, the central matrix is the fundamental object that specifies the equivalence class. In the form of Eq. (16), it is clear that the three matrices \(N_1\), \(N_2\), and \(N_3\) belong to the Fourier transposed family. A result, the two-parameter family itself belongs to the Fourier transposed family.

Let us note here that only the right equivalence is natural for more than two bases as it states that bases are defined up to permutations and global phases of their basis states. In particular, the distance between bases is invariant under right equivalence but not under left equivalence.

### C. Average distance

Let us now compute the global maximum of the ASD between the three bases. Since the three bases are equidistant, we only have to compute the distance between, say, \(M_1\) and \(M_2\). A direct calculation leads to the following expression

\[
D_{12}^2(\theta_x, \theta_t) = \frac{8}{45} \left[ 5 - P(\sin(\theta_x), \cos(\theta_t + \frac{1}{3} \pi)) \right],
\]

(17)

with the polynomial

\[
P(p, q) = 8p^8 + 8q^7p^6 - 16q^3p^5 \\
+ 16qp^5 - 16q^2p^4 + 8q^3p^3 \\
- 7p^4 - 14qp^3 + 8q^2p^2 \\
+ 2p^2 + 4qp.
\]

(18)

We denote by \((p_{\text{opt}}, q_{\text{opt}})\) the \((p, q)\) pair for which \(P(p, q)\) is minimal and, therefore, \(D_{12}(\theta_x, \theta_t)\) is maximal. It turns out that \(q_{\text{opt}}\) is related to \(p_{\text{opt}}\) by

\[
\cos(\theta_{t_{\text{opt}}} + \frac{1}{3} \pi) = q_{\text{opt}} = \frac{1 - 2p_{\text{opt}}^2}{p_{\text{opt}}},
\]

(19)

which is a particular evaluation of the function defined in Eq. (7), and \(p_{\text{opt}}^2\) is the unique real solution of a cubic equation,

\[
112p_{\text{opt}}^6 - 192p_{\text{opt}}^4 + 111p_{\text{opt}}^2 = 22,
\]

(20)

that is

\[
\sin(\theta_{x_{\text{opt}}})^2 = p_{\text{opt}}^2 = \frac{3 + 16r - r^2}{28r} = 0.6946
\]

(21)

with \(r = (21\sqrt{3} - 36)^{1/3} = 0.7199\). It follows that there are eight optimal pairs of phases \((\theta_{x_{\text{opt}}}, \theta_{t_{\text{opt}}})\) for which the maximal distance \(D_{12}^\text{max}\) is reached. The above expressions for \(\theta_{x_{\text{opt}}}^2\) and \(\theta_{t_{\text{opt}}}^2\) can be injected back into the formula of the distance to obtain first \(D_{12}^\text{max}\) and then

\[
\overline{D^2_{\text{max}}} = \frac{1}{70} \left[ 71 - 12 \cos(\theta_{x_{\text{opt}}}^2)^4 \right]
\]

\[
= \frac{1}{70} \left[ 71 - 3 \left( \frac{r^2 + 12r - 3}{14r} \right)^2 \right] = 0.9983
\]

(22)

which agrees with the numerically-found maximum ASD within the machine precision.

Furthermore, the distance \(D_{12}\) vanishes for

\[
\theta_x = \frac{\pi}{2}, \quad \theta_t = 0 \pmod{2\pi/3}
\]

and \(\theta_x = -\pi/2, \quad \theta_t = \pi/3 \pmod{2\pi/3}\).

(23)

As can be verified from the parameterization \([8]\) or from the matrix products \([5]\), the bases are indeed identical up to global phases and permutations for these values of the two phases \(\theta_x\) and \(\theta_t\).

We can also consider the single-parameter family that we obtain when eliminating \(\theta_t\) by using Eq. (7). Since Eq. (19) is equivalent to Eq. (7), this single-parameter
family reaches the maximum of the ASD — and also the minimum since Eq. (19) is obeyed by \((\theta_x, \theta_t) = (\pi/2, 2\pi/3)\). This is illustrated in Fig. 2 a contour plot of \(D^2\) for the two-parameter family of Hadamard bases, with the location of the \((\theta_x, \theta_t)\) values of the single-parameter family indicated. The location of one of the eight maxima is marked, and the locations of the other seven follow from the symmetry properties of the contours.

V. SUMMARY AND OUTLOOK

We performed a numerical search for the maximum ASD between four bases in dimension six. We found that it is strictly smaller than unity and so confirmed the recent study by Butterley and Hall [23]. We regard this result as strong evidence that no four MUB exist in dimension six.

Next, we went beyond this numerical result by providing the four bases behind the numerically-found maximum. More specifically, we found a two-parameter family of three bases, which together with the canonical basis, reaches the maximum of the ASD. We characterized this two-parameter family in full. We proved its inclusion in the Fourier transposed family and shown that the three bases are equidistant. Furthermore, we analytically computed the maximum ASD between these three Hadamard bases and the canonical basis to show that it reproduces the numerical result.

Two directions might be relevant for an extension of the present study. First, it would be interesting to see if the optimality of our solution can be extended to a larger family of bases, for example, to the whole Fourier transposed family. Second and complementarily, there might exist an argument to restrict the search for the maximum ASD between the canonical basis and three Hadamard bases to the Fourier transposed family, instead of the entire Hadamard family which, so far, has not been fully parameterized. In this context, however, it should be noted that—as follows from the findings of Jaming et al. [27]—there are no four MUB if one restricts the search to members of the Fourier family.

Finally, if there is no complete set of seven MUB in dimension six, the optimal measurement for state tomography, in terms of statistical errors, remains to be found.

Appendix A: Numerical method

As discussed in Sec. 3.1 of Ref. [2], for any ket \(|\varphi\rangle\) or bra \(\langle\phi|\) in a \(d\)-dimensional Hilbert space \(H\) or \(H^\dagger\), respectively, there is a conjugate bra or ket

\[
\mathcal{H} \ni |\varphi\rangle \leftrightarrow \langle\varphi^*| \in H^\dagger, \\
\mathcal{H}^\dagger \ni \langle\phi| \leftrightarrow |\phi^*\rangle \in H
\]

such that

\[
\langle\varphi^*|\phi^*\rangle = \langle\varphi|\phi\rangle^* = \langle\phi|\varphi\rangle. \quad (A1)
\]

This mapping is not unique, but two different realizations differ at most by a unitary transformation. As a rule, \(\langle\varphi^*|\) and \(\langle\phi|\) are different bras.

Once a particular choice of mapping has been made, there is a one-to-one correspondence between one-qudit operators and two-qudit kets,

\[
|\varphi\rangle\langle\phi| \in B(H) \leftrightarrow |\varphi^*, \varphi\rangle \in H \otimes H. \quad (A3)
\]

In particular, for an orthonormal basis of kets in \(H, a = \{|a_1\rangle, |a_2\rangle, \ldots, |a_d\rangle\}\), we have the conjugate basis \(a^* = \{|a_1^*\rangle, |a_2^*\rangle, \ldots, |a_d^*\rangle\}\), and jointly they are used in defining the two-qubit state

\[
\rho_a = \frac{1}{d} \sum_{j=1}^{d} |a_j^* a_j\rangle\langle a_j^* a_j|, \quad (A4)
\]

which has the \(d\)-fold eigenvalue \(1/d\) and the \((d^2 - d)\)-fold eigenvalue zero.

We normalize the Hilbert-Schmidt inner product of two-qudit operators in accordance with

\[
(A, B) = d \text{Tr}\{A^\dagger B\}, \quad (A5)
\]

so that \((\rho_a, \rho_a) = 1\) and \((\rho_a, \rho_b) = 1/d\) for a pair of unbiased bases. For the two-qudit states associated with two single-qudit bases, we then have

\[
\rho_a \rho_b = \frac{1}{d} \sum_{j,k=1}^{d} |a_j b_k\rangle\langle a_j b_k| = 1 - \frac{d - 1}{d} D_{ab}^2 \quad (A6)
\]

with the distance \(D_{ab}\) of Eq. (2), where the identity \(\langle a_j^* a_j | b_k^* b_k\rangle = |\langle a_j | b_k\rangle|^2\) is used. It follows that \(D_{ab}\) can be expressed in terms of the Hilbert-Schmidt norm of \(\rho_a - \rho_b\),

\[
D_{ab} = \sqrt{\frac{1}{2} \frac{1}{d-1} \|\rho_a - \rho_b\|} \quad (A7)
\]

with \(|A| = \sqrt{(A, A)}\). This tells us something important: If \(a \neq b\), then \(\rho_a \neq \rho_b\), so that the mapping \(a \leftrightarrow \rho_a\) is one-to-one.

In passing, we note the following challenge. Clearly, not all two-qudit states with \(\rho = d \rho^2\) correspond to a single-qudit basis in the sense of Eq. (A4). But which
additional criteria identify the set of two-qudit states that do?

We are interested in finding the maximum value of the ASD between \( k \) bases in dimension \( d \). The numerical search begins with a randomly chosen initial set of bases, and then modifies the bases in each iteration round such that \( D^2 \) is systematically increased.

An infinitesimal variation of a ket in basis \( a \) is given by

\[
\delta |a_j\rangle = i\epsilon_a |a_j\rangle,
\]

where \( \epsilon_a \) is an infinitesimal hermitian operator acting on the basis \( a \). We have one such hermitian \( \epsilon \) operator for each basis. The resulting response of \( D^2 \) is

\[
\delta D^2 = \sum_{a=1}^k \text{tr}\{\epsilon_a G_a\},
\]

where \( \text{tr}\{ \} \) is a single-qudit trace and

\[
G_a = \frac{8}{k(k-1)(d-1)} \text{Im}\left\{ \sum_{b=1}^k \sum_{j,k=1}^d (|a_j\rangle\langle a_j| b_k\rangle\langle b_k|)^2 \right\}
\]

is the \( a \)th component of the gradient. If bases \( a \) and \( b \) are unbiased, there is no contribution to \( G_a \) from basis \( b \) and, therefore, there is no gradient for a set of MUB. But the converse is not true: We can have a vanishing gradient although the bases are not pairwise unbiased.

When the gradient has nonzero components, we choose \( \epsilon_a = \kappa G_a \) with a common \( \kappa > 0 \) that specifies the step size. This guarantees \( \delta D^2 > 0 \) if \( \kappa \) is not too large, and maximization along the line specified by the direction of the gradient can be done by optimizing the value of \( \kappa \). The line optimization is a necessary ingredient if conjugate gradients are used for accelerating the convergence; see Ref. [28], for instance.

The finite unitary change of basis \( a, |a_j\rangle \rightarrow V_a |a_j\rangle \), is then accomplished by

\[
V_a = e^{i\epsilon_a},
\]

or

\[
V_a = \frac{1 + i\epsilon_a/2}{1 - i\epsilon_a/2}
\]

or

\[
V_a = (1 + i\epsilon_a) \prod_{n=0}^{\infty} \left[ 1 + e^{i2\pi/3} (\epsilon_a^2)^{3^n} \right]
\]

or yet other ones, whichever of them is convenient to use. All three \( V_a \)s equal \( 1 + i\epsilon_a \) to first order in \( \epsilon_a \) and differ in the higher-order terms. Note that a high-precision evaluation of the infinite product in the third version of \( V_a \) requires very few terms. This makes the third version a viable alternative if the computation of the exponential in the first version or of the inverse operator in the second version is time consuming or imprecise.

The iteration is terminated, when all components of the gradient vanish (in the numerical sense specified by the machine precision). We repeat this steepest-ascent search many times to ensure that we find the global maximum. As Fig. 1 shows for \( (d, k) = (6, 4) \), the iteration gets stuck in local maxima for about three attempts in ten and, see Table 1, only four in ten trials are successful for \( (d, k) = (6, 7) \).

Appendix B: Derivation of the two-parameter family

The \( d \times d \) matrix \( U_{ab} \) composed of the transition amplitudes \( \langle a_j| b_k \rangle \) of two orthonormal bases is unitary,

\[
U_{ab} = \begin{bmatrix}
\langle a_1| \\
\langle a_2| \\
\vdots \\
\langle a_d|
\end{bmatrix}
\begin{bmatrix}
|b_1\rangle, |b_2\rangle, \ldots, |b_d\rangle
\end{bmatrix} = U_{ba}^\dagger,
\]

\[
U_{ab} U_{ba} = \mathbb{1}.
\]

The columns and the rows of \( U_{ab} \) are representations of the kets \( |b_k\rangle \) and the bras \( \langle a_j| \), respectively. The unitary matrices associated with a set of bases have a composition law for consecutive basis changes: \( U_{ab} = U_{ac} U_{cb} \), \( U_{aa} = \mathbb{1} \). In particular, \( \sqrt{d} U_{ab} \) is a complex Hadamard matrix if the bases \( a \) and \( b \) are unbiased; see the paragraph containing Eq. 4.

Now, from the numerical search we know that one of the bases that maximize the ASD between four bases in dimension six is unbiased with the other three bases. We identify this privileged basis as the canonical basis and refer to it as the zeroth basis, and characterize the set of four bases by the three \( 6 \times 6 \) transition matrices

\[
M_1 = U_{01}, \quad M_2 = U_{02}, \quad M_3 = U_{03},
\]

so that the columns of \( M_i \) are composed of the probability amplitudes of the kets of the \( i \)th basis with respect to the privileged basis.

When multiplied by \( \sqrt{d} \), the matrices \( M_1, M_2, \) and \( M_3 \) are \( 6 \times 6 \) Hadamard matrices, for which we use Karlsson’s parameterization [25].

His parameterization applies to \( H_2 \)-reducible Hadamard matrices that can be written in the form \( H = X_L P_L N P_R X_R \), where the left and right \( X \) matrices only contain phases on the diagonal, the \( P \) matrices are permutation matrices, and the central matrix has the form

\[
N = \begin{bmatrix}
F_2 & T_1 & T_2 \\
T_3 & \frac{1}{2} T_3 A T_1 & \frac{1}{2} T_3 B T_1 \\
T_4 & \frac{1}{2} T_4 B T_1 & \frac{1}{2} T_4 A T_2
\end{bmatrix},
\]

where \( F_2 \) is the unnormalized two-dimensional Fourier matrix of Eqs. 5 and the \( 2 \times 2 \) \( T_i \) matrices are those of Eq. 10.

\[
T_i = \begin{bmatrix}
1 & t_i \\
1 & -t_i
\end{bmatrix}
\]

with \( |t_i| = 1 \),
with the central matrices given by

\[ A = F_2 \left( \frac{1}{2} \mathbb{I} + \frac{\sqrt{3}}{2} \Lambda \right), \]
\[ B = F_2 \left( \frac{1}{2} \mathbb{I} - i \frac{\sqrt{3}}{2} \Lambda \right) \]  \hspace{1cm} (B5)

with a unitary and hermitian $2 \times 2$ matrix $\Lambda$. It turns out that our Hadamard matrices are indeed $H_2$-reducible since they can be written as $M_i = X_L, P_L, N_i P_R, X_R$, with the central matrices given by

\[
N_1 = \frac{1}{\sqrt{6}} \begin{bmatrix} F_2 & F_2 & F_2 \\ F_2 & \omega F_2 & \omega^* F_2 \\ T & \omega^* T & \omega T \end{bmatrix},
\]
\[
N_2 = \frac{1}{\sqrt{6}} \begin{bmatrix} F_2 & F_2 & F_2 \\ F_2 & T & \omega T \\ T & \omega T & \omega^* T \end{bmatrix},
\]
\[
N_3 = \frac{1}{\sqrt{6}} \begin{bmatrix} F_2 & F_2 & F_2 \\ F_2 & \omega^* F_2 & \omega F_2 \\ T & \omega^* T & \omega T \end{bmatrix}; \hspace{1cm} (B6)
\]

see Eqs. (6).

As in Eqs. (5), we choose to express the matrix $T$ with factors of $\omega = \exp(i2\pi/3)$,

\[
T = \begin{bmatrix} 1 & \omega t^2 \\ 1 & -\omega t^2 \end{bmatrix}, \hspace{1cm} (B7)
\]

to exhibit the crucial dependence on the phase factor $t$.

The left permutation matrices are all equal, $P_{L_1} = P_{L_2} = P_{L_3} = P_L$.

Third, we notice that only the left dephasing and permutation matrices are relevant for the distance. Indeed the right dephasing matrices only add global phases to the basis vectors while the right permutation only permute the basis vectors. In other words, two bases $B$ and $BP_RX_R$ are equivalent in terms of distance. Therefore we can choose to conserve only the relevant structure for our bases, that is, $M_i = X_L, P_L, N_i$.

The fourth step is to use the fact that only relative dephasing and permutations of the rows are relevant to the distance. Therefore we define new bases as

\[
M_1 \equiv P_L^t X_2^t X_1 P_L N_1, \\
M_2 \equiv N_2, \\
M_3 \equiv P_L^t X_2^t X_3 P_L N_3. \hspace{1cm} (B8)
\]

To simplify the notations, we again denote the two new diagonal matrices in $P_L^t X_2^t X_1 P_L$ and $P_L^t X_2^t X_3 P_L$ by $X_1$ and $X_3$, respectively. We further observe that

\[
X_1 = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_1 \end{bmatrix} \hspace{1cm} \text{and} \hspace{1cm} X_3 = \begin{bmatrix} B_1 & 0 & 0 \\ 0 & B_2 & 0 \\ 0 & 0 & B_3 \end{bmatrix}. \hspace{1cm} (B9)
\]

Next we add a suitable global phase to $X_1$ and $X_3$. We multiply $X_1$ by $\exp(-i\arg(A_1[1,1]A_1[2,2]/2))$ and $X_3$ by $\exp(-i\arg(B_1[1,1]B_1[2,2]/2))$ such that $A_1$ and $B_1$ take the simple form

\[
\begin{bmatrix} \exp(-i\phi) & 0 \\ 0 & \exp(i\phi) \end{bmatrix}, \hspace{1cm} (B10)
\]

for some phase $\phi$. We end up with the remarkable form

\[
X_1 = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_1 \end{bmatrix}, \hspace{1cm} X_3 = \begin{bmatrix} A_1^* & 0 & 0 \\ 0 & \omega A_1^* & 0 \\ 0 & 0 & B_3 \end{bmatrix} \hspace{1cm} (B11)
\]

where [cf. Eqs. (9)]

\[
A_1 = \begin{bmatrix} x^* & 0 \\ 0 & x \end{bmatrix}. \hspace{1cm} (B12)
\]

So far, we have found that

\[
A_3 = A_1, \\
B_1 = A_1^*, \\
B_2 = \omega^* A_1^*, \hspace{1cm} (B13)
\]

and it only remains to find the structure behind the two $2 \times 2$ dephasing matrices $A_2$ and $B_3$.

To do so, we now consider the products $U_{ij} = M_i^t M_j$. We obtain

\[
M_1^t M_2 = \begin{bmatrix} a_1 & a_2 & a_3 \\ a_3 & a_1 & a_2 \\ a_2 & a_3 & a_1 \end{bmatrix} \hspace{1cm} \text{with} \hspace{1cm} \begin{bmatrix} a_1 \\ a_2 \\ a_3 \end{bmatrix} = F_3 \begin{bmatrix} F_2 A_1^* F_2 \\ F_2 A_2^* T \\ T^* A_3^* T \end{bmatrix} \hspace{1cm} (B14)
\]

and $F_3$ is the standard (unnormalized) 3-dimensional Fourier matrix

\[
F_3 = \begin{bmatrix} 1 & 1 & 1 \\ 1 & \omega & \omega^* \\ 1 & \omega^* & \omega \end{bmatrix}. \hspace{1cm} (B15)
\]

Similarly we have

\[
M_2^t M_3 = \begin{bmatrix} b_1 & b_2 & b_3 \\ b_3 & b_1 & b_2 \\ b_2 & b_3 & b_1 \end{bmatrix} \hspace{1cm} \text{with} \hspace{1cm} \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix} = F_3 \begin{bmatrix} F_2 B_1 F_2 \\ T^* B_2 T \\ T^* B_3 F_2 \end{bmatrix} \hspace{1cm} (B16)
\]

and

\[
M_3^t M_1 = \begin{bmatrix} c_1 & c_2 & c_3 \\ c_3 & c_1 & c_2 \\ c_2 & c_3 & c_1 \end{bmatrix} \hspace{1cm} \text{with} \hspace{1cm} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} = F_3 \begin{bmatrix} F_2 Y_1 F_2 \\ T^* Y_2 F_2 \\ F_2 Y_3 T \end{bmatrix} \hspace{1cm} (B17)
\]
The seventh step is to look once more at the numerics. With respect to the product $M_1^t M_2$, we see that

$$a_2 = \omega^* Z a_3 Z .$$

(B19)

Thus we are lead to define the matrix equation

$$E_1 \hat{=} a_2 - \omega^* Z a_3 Z = 0 .$$

(B20)

This only represents a system of three equations since $E_1[1, 1] = E_2[2, 2]$. In the same manner, we have for $M^t_2 M_3$

$$E_2 \hat{=} b_1 - \omega^* Z b_3 Z = 0 ,$$

(B21)

and $E_2[1, 1] = E_2[2, 2]$ so that, here too, only three equations are relevant. Finally, for $M^t_1 M_1$, we obtain

$$E_3 \hat{=} c_1 + Z c_2 Z = 0$$

(B22)

and, owing to $(\omega^* - 1) E_3[1, 2] = t (1 - \omega) E_3[2, 1]$, again only three equations are relevant. We should mention here that there are other interesting identities within the products $M^t_1 M_1$, such as $b_2 = [a_1 + a_1^* + Z (a_1 - a_1^*) Z] / 2$, but they are much more complicated to handle and will not be necessary to achieve our parameterization.

The eighth step is to solve the above nine equations. We obtain

$$E_1[1, 1] : \text{tr} \{ A_1 \} = \text{tr} \{ A_3 \} ,$$

$$E_1[1, 2] : A_1 - 2 \omega^* t^2 A_2 + \omega^* t^2 A_3 = r \mathbb{I} ,$$

$$E_1[2, 1] : \omega^* t^2 A_1 - 2 \omega^* t^2 A_2 + A_3 = r \mathbb{I} .$$

(B23)

From the numerics, we know that $r = r'$ and thus $A_1 = A_2$, which we already found by looking at the dephasing matrix $X_1$. Note also that the expression of the complex number $r$ is not required. Furthermore we find

$$E_2[1, 1] : \text{tr} \{ B_1 \} = \omega \text{tr} \{ B_2 \} ,$$

$$E_2[1, 2] : \omega^* t^2 B_1 + \omega B_2 - 2 \omega^* t^2 A_2 = s \mathbb{I} ,$$

$$E_2[2, 1] : B_1 + t^2 B_2 - 2 \omega^* t^2 B_3 = s' \mathbb{I} .$$

(B24)

From the numerics, we know that $s = s' (= r)$ and thus $B_1 = \omega B_2$, which we already obtained by looking at the dephasing matrix $X_3$. The next three equations are much more interesting. Indeed we have

$$E_3[1, 1] : 2 \text{tr} \{ Y_1 \} - \omega^* \text{tr} \{ Y_2 \} - \omega \text{tr} \{ Y_3 \} = 0 ,$$

$$E_3[2, 2] : 2 \text{tr} \{ Y_1 \} - \omega^* t^2 \text{tr} \{ Y_2 \} - \omega^* t^2 \text{tr} \{ Y_3 \} = 0 ,$$

$$E_3[1, 2] : t^2 Y_2 - Y_3 = u \mathbb{I} .$$

(B25)

From the numerics, we know that $u = 0$ and the last equation reduces to

$$Y_3 = t^* 2 Y_2 .$$

(B26)

Since $Y_2 = \omega A_1 A_2$ and $Y_3 = B_3^t A_1$, the above equation directly translates into

$$B_3 = \omega^* t^2 A_3^* .$$

(B27)

This last relation can be inserted in $E_3[1, 1]$ and $E_3[2, 2]$, which become identical and can be written as

$$2 \text{tr} \{ Y_1 \} - (\omega^* + \omega t^2) \text{tr} \{ Y_2 \} = 0 .$$

(B28)

This equation will soon become Eq. (7).

A last hint from the numerics is needed. We actually notice that

$$Y_1 Y_2 Y_3 = - \mathbb{I} .$$

(B29)

As $Y_3 = t^* 2 Y_2$, we arrive at $t^* 2 Y_1 Y_2^* = - \mathbb{I}$ so that $\omega^* A_1^2 A_2^* = \pm i U$, where $U^2 = \mathbb{I}$, that is, $U = \mathbb{I}$ or $U = Z$ since it has to be diagonal. With the help of the numerics, we conclude that

$$A_2 = i \omega^* t Z A_1^2$$

and consequently

$$B_3 = - i t Z A_1^2 .$$

(B30)

(B31)

The final parametrization of the dephasing matrices is therefore given by

$$X_1 = \begin{bmatrix} A_1 & 0 & 0 \\ 0 & i \omega^* t Z A_1^2 & 0 \\ 0 & 0 & A_1 \end{bmatrix} ,$$

$$X_3 = \begin{bmatrix} A_1^* & 0 & 0 \\ 0 & \omega^* A_1^* & 0 \\ 0 & 0 & - i t Z A_1^2 \end{bmatrix} .$$

(B32)

which are ingredients in Eqs. (6).

Let us finally come back to Eq. (B28). We can now substitute $Y_1 = A_1^2$ and $Y_2 = (i \omega^* t Z A_1^2) (\omega A_1) = i t Z A_1^2$ in Eq. (B28) and, upon defining $x = \exp(i \theta_x)$ and $t = \exp(i \theta_t)$, we arrive at

$$\cos(\theta_t - 2 \pi / 3) = - \frac{\cos(2 \theta_x)}{\sin(\theta_x)} ,$$

which is Eq. (7).
