Abstract

We discuss coherent QCD radiation from space-like parton branching and its effects on multi-jet final states at high-energy hadron colliders. Coherence effects for small longitudinal momentum fractions $x$ are not included in the branching algorithms of standard shower Monte Carlo event generators. On the other hand, they are taken into account only partially in perturbative next-to-leading-order calculations for multi-jets. Such effects are present to all orders in $\alpha_s$ and can become logarithmically enhanced with $\sqrt{s}/E_T$, where $E_T$ is the hardest jet transverse energy. We present results of summing coherence effects to all orders by parton-branching Monte Carlo methods based on transverse-momentum dependent matrix elements.

We discuss coherent QCD radiation from space-like parton branching and its effects on multi-jet final states at high-energy hadron colliders. Coherence effects for small longitudinal momentum fractions \( x \) are not included in the branching algorithms of standard shower Monte Carlo event generators. On the other hand, they are taken into account only partially in perturbative next-to-leading-order calculations for multi-jets. Such effects are present to all orders in \( \alpha_s \) and can become logarithmically enhanced with \( \sqrt{s}/E_T \), where \( E_T \) is the hardest jet transverse energy. We present results of summing coherence effects to all orders by parton-branching Monte Carlo methods based on transverse-momentum dependent matrix elements.

Studies of final states containing multiple hadron jets at the forthcoming LHC require realistic event simulation by parton shower Monte Carlo \cite{1}, including validation and tuning of the event generators using multi-jet data from Tevatron and HERA, see e.g. \cite{2,3,4}.

Standard parton-shower generators, such as \textsc{Herwig} and \textsc{Pythia}, are based on collinear evolution of the jets developing (both “forwards” and “backwards”) from the hard event. Besides small-angle, incoherent gluon emission, the approach of these generators also incorporates coherent soft-gluon emission from partonic lines carrying longitudinal momentum fraction \( x \sim O(1) \). The phenomenological relevance of this treatment has been emphasized by extensive collider data studies \cite{5}.

However at the LHC, due to the phase space opening up for large center-of-mass energies, jet production enters a new regime with a great many events characterized by multiple hard scales, in which (a) effects of emissions that are not collinearly ordered become increasingly non-negligible, and (b) coherence effects set in from space-like partons carrying momentum fractions \( x \ll 1 \) (Fig. 1) \cite{6}. These effects are not included in standard shower Monte Carlo generators. It is not at all obvious that the approximations involved in Monte Carlo that have successfully served for event simulation in past collider experiments will be up to the new situation.

The theoretical framework to take account of non-collinear emission and coherence in the space-like branching requires the introduction of partonic distributions unintegrated not only in the longitudinal momenta but also in the transverse momenta \cite{7,8,9,10,11}. The corrections to

\begin{equation}
\begin{aligned}
P \quad \alpha \\
\vdots \quad \alpha_1 \\
xP \\

P &= \quad \rightarrow + \quad \leftarrow + \quad ..
\end{aligned}
\end{equation}

Figure 1. (top) Coherent radiation in the space-like parton shower for \( x \ll 1 \); (bottom) the unintegrated splitting function \( P \), including small-x virtual corrections.

collinear ordering correspond to higher-order radiative terms in the associated jet distributions that are logarithmically enhanced in the ratio
\( \sqrt{s}/E_T \) of the total energy \( \sqrt{s} \) to the jet transverse energy. An alternative approach to non-collinear gluon radiation is based on showers of color dipoles \cite{12} and is also being applied to the initial-state jet \cite{13,14}. See \cite{15} for a study of critical issues in the relation of this approach with the parton formulation. Either at parton or dipole level, open questions involve methods for properly combining contributions from infrared regions with high-energy subgraphs, for which we expect techniques such as those in \cite{16} to be relevant. An overview of issues on unintegrated distributions and references may be found in \cite{11}.

Figure 2. Measurement of 3-jet cross section \cite{4} versus azimuthal separation between the two highest-\( E_T \) jets, compared with NLO results.

The effects of coherent space-like branching are investigated in \cite{6} for angular and momentum correlations in multi-jet final states. For a multi-jet event, consider for instance the distribution in the azimuthal angle \( \Delta \phi \) between the two hardest jets. At the LHC such measurements may become accessible relatively early and be used to probe the description of complex hadronic final states by QCD and Monte Carlo generators. Experimental data on \( \Delta \phi \) correlations are available from the Tevatron \cite{3} and from Hera \cite{4}. While the Tevatron measurements are dominated \cite{6} by leading-order QCD processes and are reasonably well described both by collinear showers (HERWIG and the new tuning of PYTHIA \cite{23}) and by fixed-order NLO calculations, the Hera \( \Delta \phi \) measurements probe higher orders in the dynamics of color emission, and present a more complex case, likely to be closer to the situation at the LHC.

![Figure 3](image2)

Figure 3. Angular jet correlations \cite{6} from \( k_{\perp} \)-shower CASCADE and from HERWIG, compared with data \cite{4}: (top) di-jet cross section; (bottom) three-jet cross section. The HERWIG results are multiplied by a K-factor equal to 2 to give the correct normalization in the two-jet region.

In particular, it is noted in \cite{6,17} that di-jet \( \Delta \phi \) correlations are affected by sizeable sub-leading corrections, resulting in large theoretical uncertainties at NLO. Analogous effects are ob-
served [4] in the three-jet cross section (Fig. 2) particularly for the small-∆φ and small-x bins. The large corrections arise from regions with three well-separated hard jets in which the parton lines in the initial state decay chain are not ordered in transverse momentum. These corrections can be treated and summed to all orders, including coherence effects, by parton branching [6], using matrix elements (ME) and distributions (u-pdf) at fixed transverse momentum $k_\perp$ according to the factorization [8]. Fig. 3 compares $k_\perp$-shower (CASCADE [18]) and collinear-shower (HERWIG) results with the measurements [4]. The shape of the angular distribution is described well by the $k_\perp$-shower. On the other hand, while the HERWIG K-factor in Fig. 3 allows one to get the normalization in the two-jet region approximately correct, the shape is not well described by HERWIG as $\Delta\phi$ decreases.

The shape of the angular distribution is described well by the $k_\perp$-shower. On the other hand, while the HERWIG K-factor in Fig. 3 allows one to get the normalization in the two-jet region approximately correct, the shape is not well described by HERWIG as $\Delta\phi$ decreases.

Figure 4. The dijet azimuthal distribution [6] normalized to the back-to-back cross section: (solid red) full result (u-pdf $\oplus$ ME); (dashed blue) no finite-$k_\perp$ correction in ME (u-pdf $\oplus$ MEcollin.); (dotted violet) u-pdf with no resolved branching.

The correlations in the jets’ azimuthal distances and in their transverse-momentum imbalance are sensitive to the large-$k_\perp$ tail in the hard matrix element [19]. Fig. 4 illustrates the relative contribution of ME and u-pdf to the result, showing different approximations to the azimuthal dijet distribution normalized to the back-to-back cross section. The solid red curve is the full result. The dashed blue curve is obtained from the same unintegrated pdf’s but by taking the collinear approximation in the hard matrix element. The dashed curve drops much faster than the full result as $\Delta\phi$ decreases, indicating that the high-$k_\perp$ component in the hard ME is necessary to describe jet correlations for small $\Delta\phi$. The dotted (violet) curve is the result obtained from the unintegrated pdf without any resolved branching. This represents the contribution of the intrinsic $k_\perp$ distribution only, corresponding to nonperturbative, predominantly low-$k_\perp$ modes. That is, in the dotted (violet) curve one retains an intrinsic $k_\perp \neq 0$ but no effects of coherence. We see that the resulting jet correlations in this case are down by an order of magnitude. The inclusion of the perturbatively computed high-$k_\perp$ correction distinguishes the calculation [6] of multi-jet cross sections from other shower approaches (see e.g. [20]) that include transverse momentum dependence in the pdfs but not in the matrix elements.

Figure 5. Transverse momentum distribution of top quark pairs [6] at the LHC from $k_\perp$-shower (CASCADE) and NLO+shower (MC@NLO).

We note that this behavior in the finite-$k_\perp$ part of the matrix element is consistent with the observation of sizeable corrections to the $\Delta\phi$ distribution at NLO [4], and supports the interpretation
of the data in Fig. 3 in terms of corrections to collinear ordering.

The coherence effects just discussed show up in the region of small $\Delta \phi$. The region of large $\Delta \phi$, on the other hand, is dominated by soft and collinear radiation [21]. But note that this region is also possibly affected by further, somewhat unexpected effects, arising from endpoint singularities [22], and possibly Coulomb exchange [23].

Besides jet final states, the corrections to collinear-ordered showers described in this article are also relevant to heavy particle production [8, 24, 25, 26]. In Fig. 5 is the result of a numerical calculation for the transverse momentum spectrum of top-antitop pair production at the LHC. Small-$x$ effects are not large in this case. Rather, this process illustrates how the showering works all the way up to virtualities on the order of the top quark mass, and finite $x$. Note that even at LHC energies the transverse momentum distribution of top quark pairs calculated from the $k_T$-shower is similar to what is obtained from a full NLO calculation (including parton showers, MC@NLO), with the $k_T$-shower giving a somewhat harder spectrum.
