The use of prognostic scales in upper gastrointestinal tract bleeding.

Type
Research paper

Keywords
gastrointestinal bleeding, prognostic scales, AIMS 65, Glasgow-Blatchford, Rockall

Abstract
Introduction
In order to select high-risk patients, many prognostic scales have been invented. Among them, Rockall, Glasgow-Blatchford and AIMS 65 scales were considered the most useful.

Material and methods
Patients with upper GI tract bleeding, treated between 2017 and 2018 were retrospectively enrolled to the study. Every patient had a Rockall, Glasgow-Blatchford and AIMS 65 score calculated retrospectively. Data on hospitalization as blood transfusions, length of hospital stay, rebleeding, intensive care unit (ICU) admission, mortality was included into data-base.

Results
Univariate logistic regression revealed that only the AIMS65 scale was a prognostic factor for in-hospital mortality (OR 11.028; 95% CI: [2.271, 53.563], p=0.001). The AIMS 65 score >2 was the only factor predicting the need of >4 blood units transfusion during hospitalization (OR 3.977; 95% CI: [1.305, 12.122], p=0.015), whereas Glasgow-Blatchford scale >5 was the only risk factor for the need of fresh frozen plasma transfusion (OR 3.657; 95% CI: [1.010-13.242], p=0.048). The area under a curve (AUC) in the ROC analysis revealed that the AIMS 65 scale was the most accurate in mortality prediction (AUC=0.859, p=0.002), whereas Rockall score and Glasgow-Blatchford were not significant (AUC=0.614, p=0.093 and AUC=0.504, p=0.97, respectively).

Conclusions
Based on our results, we recommend using AIMS 65 scoring system. It’s simple and requires few of parameters to be counted. Also, it proved to be the most efficient in predicting in-hospital mortality.
Abstract:

In order to select high-risk patients, many prognostic scales have been invented. Among them, Rockall, Glasgow-Blatchford and AIMS 65 scales were considered the most useful.

Materials and methods: Patients with non-variceal upper GI tract bleeding, treated between 2017 and 2018 were retrospectively enrolled to the study. Every patient had a Rockall, Glasgow-Blatchford and AIMS 65 score calculated retrospectively. Data on hospitalization as blood transfusions, length of hospital stay, rebleeding, intensive care unit (ICU) admission, mortality was included into data-base.

Results: Univariate logistic regression revealed that only the AIMS65 scale was a prognostic factor for in-hospital mortality (OR 11.028; 95% CI: [2.271, 53.563], p=0.001). The AIMS 65 score >2 was the only factor predicting the need of >4 blood units transfusion during hospitalization (OR 3.977; 95% CI: [1.305, 12.122], p=0.015), whereas Glasgow-Blatchford scale >5 was the only risk factor for the need of fresh frozen plasma transfusion (OR 3.657; 95% CI: [1.010-13.242], p=0.048). The area under a curve (AUC) in the ROC analysis revealed that the AIMS 65 scale was the most accurate in mortality prediction (AUC=0.859, p=0.002), whereas Rockall score and Glasgow-Blatchford were not significant (AUC=0.614, p=0.093 and AUC=0.504, p=0.97, respectively).

Conclusions: Based on our results, we recommend using AIMS 65 scoring system. It's simple and requires few of parameters to be counted. Also, it proved to be the most efficient in predicting in-hospital mortality.

1. Introduction

Despite improvement in the medical treatment of peptic ulcer disease through the use of proton pump inhibitors (PPIs), the incidence of upper gastrointestinal bleeding remains high. Estimates of the incidence of upper GI bleeding range between 50 to 150 cases per 100,000 citizens annually, depending on geographic localization [1]. Moreover, the incidence of patients requiring anticoagulant and anti-platelet medications due to cardiac or vascular comorbidity continues to rise [2,3]. These patients are also more commonly treated for concomitant diseases such as diabetes or chronic renal insufficiency, which may worsen the overall prognosis. The overall mortality related to upper GI bleeding varies between 2 - 2.5% [4,5].

In order to select high-risk patients, many prognostic scales have been invented. Among them, Rockall, Glasgow-Blatchford and AIMS 65 scales were considered the most useful. A Rockall score assesses patient age, symptoms of shock, concomitant diseases and endoscopic findings[4]. Whereas the Glasgow-Blatchford scale is based on hemodynamic parameters, hemoglobin count, symptoms of GI tract bleeding and presence of cardiac and hepatic diseases [6]. A recently introduced score called AIMS 65 takes into consideration albumin level, INR, blood pressure, mental status and age [7]. However, despite their value, none of these scales are widely used in clinical practice. There is a lack of data on which scale offers the most accurate risk stratification in patients with acute upper GI bleeding. Therefore, we designed a study comparing all three scales.

2. Aim of the study:

The aim of the study was to compare different scoring systems (Rockall score, Glasgow-Blatchford, AIMS 65) as a toll for mortality prediction in patients with non-variceal upper GI bleeding.

3. Materials and methods
Patients with non-variceal upper GI tract bleeding, treated between January 2017 and December 2018 in 2nd Department of General Surgery of the Jagiellonian University, were retrospectively enrolled to the study.

Patients presenting with symptoms of GI bleeding, such as hematemesis, melena, coffee ground vomiting or blood in the nasogastric tube, were considered for endoscopic examination. The Forrest scale was used to classify severity of bleeding [8]. In case of active bleeding, injection of adrenaline with 10% saline solution was used to achieve hemostasis. Forrest Ia bleeding and Forrest IIa ulcers were additionally secured by an endoclip. Every patient has had constant 8 mg/hour PPI infusion. All patients had basic biochemistry, CBC and vital parameters assessed. Blood transfusion was indicated when hemoglobin count dropped below 7g/dL, or the hematocrit level was below 21%, or signs of hemodynamic instability were present, despite fluid injection. Fresh Frozen Plasma was transfused in case of coagulation disorders (INR>1,3, APTT> 36s). Every patient had a clinical Rockall, Glasgow-Blatchford and AIMS 65 score calculated retrospectively. Data on hospitalization as blood transfusions, length of hospital stay, rebleeding, intensive care unit (ICU) admission, mortality was included into data-base. Primary endpoint was in-hospital mortality. Secondary endpoints were bleeding recurrence, need for blood and fresh frozen plasma transfusion.

Statistical analysis and ethical consideration

All data was analyzed with Statistica version 13.0 PL (StatSoft Inc., Tulsa, OK, USA). The results are presented as mean standard deviation (mean ±SD), median, and interquartile range (IQR). The study of categorical variables used the chi-square test of independence. The Shapiro-Wilk test was used to check for normal distribution of data and the Student t test was used for normally distributed quantitative data. For non-normally distributed quantitative variables, the Mann-Whitney U test was used. A p-value < 0.05 was considered statistically
significant. All considerable patient- and treatment-related factors were analyzed in univariate logistic regression models, then significant factors were analyzed in the multiple logistic regression model in search of independent risk factors for blood and fresh frozen plasma transfusion and rebleeding or in-hospital mortality. The results are presented as Odds Ratio (OR) and Confidence Interval (CI). Receiver operating characteristic curves with area under curve (AUC) calculation were used to compare the scoring systems in terms of sensitivity and specificity. Youden index was used to select cut-off points.

All procedures were performed in accordance with the ethical standards of the 1964 Declaration of Helsinki and its later amendments (Fortaleza 2013). The study was approved by the Local Ethics Committee of the Jagiellonian University Medical College (KBN no 122.6120.36.2016).

3. Results

137 patients were included in the analysis. Mean age was 64.13 ± 16.04.

The median AIMS65 score was 1 (IQR: 1-2). There were 15 patients (10.95%) with high risk of in-hospital mortality. 118 (86.13%) patients had Glasgow-Blatchford score >6, which stratifies the risk of needing an intervention as >50%. Median Glasgow-Blatchford score was 10 (IQR: 8-13). Median Rockall score was 5 (IQR: 3-6). There were 6 (4.38%) patients with high risk of mortality. The summary is included in Table 2. Six (4.38%) patients died during hospitalization. Univariate logistic regression revealed that only the AIMS65 scale was a prognostic factor for in-hospital mortality (OR 11.028; 95% CI: [2.271, 53.563], p=0.001).

The results of univariate logistic regression are shown in Table 3. The area under a curve (AUC) in the ROC analysis revealed that the AIMS 65 scale was the most accurate in mortality prediction (AUC=0.859, p=0.002), whereas Rockall score and Glasgow-Blatchford were not significant (AUC=0.614, p=0.093 and AUC=0.504, p=0.97, respectively).
There were 11 patients with bleeding recurrence during their hospitalization. ROC analysis revealed that the AIMS 65 and Glasgow-Blatchford score were comparable in rebleeding prediction (AUC=0.735; p=0.004 and AUC=0.737; p=0.001 respectively). The Rockall score had lower accuracy (AUC=0.56; p=0.451).

102 patients required blood transfusions during hospitalization and 29 patients required more than 4 units of packed red blood cells. 51 patients required fresh frozen plasma transfusions. The data are summarized in table 1.

The AIMS 65 score >2 was the only factor predicting the need of >4 blood units transfusion during hospitalization (OR 3.977; 95% CI: [1.305, 12.122], p=0.015), whereas Glasgow-Blatchford scale >5 was the only risk factor for the need of fresh frozen plasma transfusion (OR 3.657; 95% CI: [1.010-13.242], p=0.048). The results are summarized in Table 4.
4. Discussion

This study has demonstrated the value of the AIMS65 scoring system, which proved to be most accurate in mortality prediction and need of blood transfusion in patients with upper GI tract bleeding.

The AIMS65 scoring system’s main objective is to stratify patients with a high risk of in-hospital mortality [7]. In our study, it was the only scoring system that helped to accurately predict in-hospital death. It stands in line with study by Robertson et al. who showed superiority of this scoring system in comparison to Glasgow-Blatchford and Rockall scale [9]. Japanese study also revealed superiority of the AIMS65 score [10]. In addition to its high accuracy, AIMS 65 system is simple and based on basic parameters [11]. On the contrary, Choe et al. suggested that both Rockall and Glasgow-Blatchford scales are more accurate in predicting the need of blood transfusion and endoscopic intervention [12]. Stanley et al., using data from six hospitals in Europe, North America, Asia and Oceania showed superiority of AIMS 65 for mortality prediction, however authors still recommended Glasgow-Blatchford scale as most accurate in general risk stratification [13]. Shafagi et al. proposed modified Glasgow-Blatchford scoring system, taking albumin level into account, as more accurate in Central European population[14].

AIMS 65 and Glasgow-Blatchford scales were comparable in prediction of rebleeding. The same findings were revealed in a study by Rout [15]. However, as the author pointed out, the AIMS 65 scale was originally invented for risk stratification of non-variceal upper GI bleedings [16].

In our study, the AIMS 65 score was also superior to the others in predicting the need for blood transfusion. Conversely, Hyett et al. underlined the superiority of the Glasgow-Blatchford scale [11]. One possible explanation for this discrepancy is the frequent use of oral anticoagulants in central Europe, which elevates INR level, one of the components of
AIMS65 scale. However, in our study the Glasgow-Blatchford scale was the only one that helped with predicting the need for plasma transfusion.

Our study has some limitations, which may affect final results. At first, the study is designed as a retrospective analysis of data, therefore some of the important data might have been missed in the medical records. Secondly, the study group is middle-sized, which may have an impact on the final results. Lastly, we did not perform a multivariate-analysis of logistic regression, because in all cases there was only one significant factor in univariate analysis.

5. Conclusion

Based on our results, we recommend using AIMS 65 scoring system. It’s simple and requires few of parameters to be counted. Also, it proved to be the most efficient in predicting in-hospital mortality.
