Abstract

The objective of our study was to describe the molecular support of carbapenem resistance from randomly selected clinical isolates of multidrug-resistant (MDR) Acinetobacter baumannii as a pilot study from the Hamad Medical Corporation (HMC), Qatar. Results of our report will be used to study carbapenemases using molecular techniques in all isolated MDR A. baumannii. Forty-eight MDR A. baumannii were randomly selected from isolates preserved at HMC. Identification of all isolates was confirmed by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry. Antibiotic resistance was tested phenotypically by Phoenix and confirmed by Etest. The molecular support of carbapenemases (blaOXA-23, blaOXA-24, blaOXA-58, blaNDM) was investigated by real-time PCR. The epidemiologic relatedness of the isolates was verified by phylogenetic analysis based on partial sequences of CsuE and blaOXA-51 genes. All 48 isolates were identified as A. baumannii and were confirmed to be resistant to most antibiotics, especially meropenem, imipenems, ciprofloxacin, levofloxacin, amikacin, gentamicin and most of the β-lactams; they were sensitive to colistin. All the isolates were positive for blaOXA-23 and negative for the other tested carbapenemase genes. Clonality analysis demonstrated that different lineages were actually circulating in Qatar; and we suggest that an outbreak occurred in the medical intensive care unit of HMC between 2011 and 2012. Here we report the emergence of MDR A. baumannii producing the carbapenemase OXA-23 in Qatar.

Introduction

Acinetobacter species are strictly aerobic nonfermenting Gram-negative coccobacilli if in the inactive phase or bacilli if in the rapid-growth phase. The Acinetobacter calcoaceticus–Acinetobacter baumannii complex comprises A. baumannii, A. pittii, A. nosocomialis, A. lwaffii and the environmental species A. calcoaceticus. Common commercial tests cannot differentiate among these species, as they share the same phenotypic tests. For daily microbiology work, speciation adds clinical value, as A. baumannii is the only species in this genus that is clinically important[1,2].

For epidemiologic studies, it is important to know the identity of the main strains or clones of the same species causing infections, especially in outbreak investigations, by determining virulence or resistance genes using genotypic studies[3,4]. Different genotypic tests have been used to study the relatedness of the Acinetobacter isolates to learn the sources of outbreaks and epidemics and the modes of intrahospital or regional transmission. These tests include PCR-based methods, mainly pulsed-field gel electrophoresis (PFGE), amplified
fragment-length polymorphism, PFGE followed by further subtyping using variable number of tandem repeat loci and finally multilocus sequence typing (clonality analysis), which is considered a powerful and discriminatory tool [1,5,6].

Mechanisms of carbapenem resistance in A. baumannii are mainly due to the production of carbapenemases, especially OXA-type carbapenem-hydrolyzing (class D) β-lactamases, which are either chromosomally located, like blaOXA-51, which become expressed only when the insertion sequence ISAba1 element is inserted upstream of the gene, or acquired, mostly expressed only when the insertion sequence ISAba1 element is

populations_status_2012_en.pdf). The expatriate workforce is kinetic; many people travel frequently—more than once a year—to their home countries. This continuous travelling facilitates the transfer of many resistant bacteria. If one of these multidrug-resistant (MDR) organisms such as A. baumannii gained access to the hospital, it is not easy to eliminate it, as the hospital environment favours its growth and transmission either by colonizing or infecting healthcare workers or living within biofilms formed by the bacteria, thus protecting it from the effects of common disinfectants.

A recent study in Qatar described the mechanisms of carbapenem resistance in eight A. baumannii isolates [8]. Ours is the second study to describe the genetic causes of carbapenem resistance among 48 MDR A. baumannii isolates. The objective of our study was to determine carbapenem resistance genes in a randomly selected number of MDR A. baumannii from isolates stored at Hamad Medical Corporation (HMC), Qatar, and to learn whether they were genetically related. The outcome of our study will help inform a project studying the magnitude of MDR A. baumannii in the last few years, the common resistance genes and the dominant clones circulating in Qatar. HMC (comprising tertiary, general and continuing care hospitals) is the principal public healthcare provider for the state of Qatar.

stored MDR isolates in the cryobank of HMC’s microbiology department, which is Qatar’s premier not-for-profit healthcare provider. Located in the state of Qatar, HMC manages eight hospitals (approximately 2600-bed capacity). All isolates were sent to Marseille in chocolate agar slants at room temperature.

Identification and antibacterial susceptibility testing

Forty-eight MDR A. baumannii were identified, and antibiotic susceptibility testing was performed by the broth microdilution method (BD Phoenix; Becton Dickinson, Franklin Lakes, NJ, USA) and confirmed for identification at URMITE (Unité des Maladies Infectieuses et Tropicales Emergentes), Marseille, France, by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI-TOF) using a MS LT spectrometer (Bruker Daltonics, Bremen, Germany) as previously described [9], with flex control software (Bruker) and MALDI Biotyper version 3.0. A score of ≥1.9 was considered positive for identification at the species level, as previously reported [9]. Confirmation of resistance by Etest (bioMérieux, Marcy l’Etoile, France) was performed. The susceptibility breakpoints used were those recommended in 2013 by the Clinical and Laboratory Standards Institute (M100-S23). Susceptibility testing by Etest was additionally done in Marseille to the following antibiotics: colistin, imipenem and sulbactam (AB Biodisk, Solna, Sweden).

The 48 isolates were collected mainly from respiratory specimens (n = 10); 11 of the patients were from the intensive care unit (ICU), two from the coronary care unit, 12 from the surgical intensive care unit, five from the intensive care unit and eight from the trauma intensive care unit (TICU) (Table I). Twenty-seven patients had comorbidities, and 15 patients died, ten of whom were ICU patients.

### TABLE I. Demographic data of 48 patients

| Characteristic         | n   |
|------------------------|-----|
| Patient age            |     |
| Adult                  | 48  |
| Child                  | 1   |
| Nationality            |     |
| Qatari                 | 14  |
| Indian                 | 6   |
| Other                  | 29  |
| Death                  | 15  |
| Length of stay         |     |
| >1 year                | 6   |
| 2–6 months             | 19  |
| Treatment received     |     |
| Colistin               | 33  |
| Tigecycline            | 5   |
| Comorbidities          | 27  |
| Diabetes mellitus      | 21  |
| Polytrauma             | 6   |
| Coinfection with Pseudomonas aeruginosa | 17 |

Materials and Methods

Bacterial strains

Forty-eight MDR A. baumannii samples of the period 2011–2012 were randomly chosen. Isolates were taken from

New Microbes and New Infections © 2016 The Authors. Published by Elsevier Ltd on behalf of European Society of Clinical Microbiology and Infectious Diseases, NMNI, 11, 47–51

Molecular detection of carbapenemase-hydrolyzing oxacillinases

DNA was extracted using the EZ1 advanced XL extractor with DNA bacteria card and the EZ1 DNA Tissue Kit (Qiagen, Courtabœuf, France) according to the manufacturer’s instructions. All 48 A. baumannii isolates were screened for the presence of resistance genes bla\textit{OXA-23}, bla\textit{OXA-24}, bla\textit{OXA-58} and bla\textit{NDM} by real-time PCR (C1000 Thermal Cycler; Bio-Rad, Hercules, CA, USA). Amplification was performed using the following thermocycler conditions: initial denaturation step at 95°C for 15 minutes, followed by 35 cycles of denaturation at 95°C for 30 seconds and extension at 60°C for 1 minute. Negative and positive controls were included in each assay.

Clonality analysis

The 48 isolates were subjected to molecular typing by clonality analysis. Genotyping was performed using the genes bla\textit{OXA51}-like and \textit{CsuE}, as previously described [10]. PCR amplification, sequencing and correction of gene sequences were performed as previously described [10]. For each of the two genes, the DNA sequences obtained from our isolates were aligned with those of the reference strains by Clustal W software. The phylogenetic relationship of our strains together with the reference strains was then determined by MEGA 5 software with the Kimura two-parameter model and bootstrap analyses based on 1000 replications [11].

Results

All isolates were confirmed as A. baumannii by MALDI-TOF Microflex (Bruker).

All isolates were resistant to imipenem, meropenem, ciprofloxacin, levofloxacin, amikacin, gentamicin, sulfamethoxazole/trimethoprim, amoxicillin/clavulanic acid, piperacillin/tazobactam, cefotaxime and ceftazidime; 39 isolates were resistant to sulbactam.

The colistin resistance rate was 0 (0/48), so treatment of these patients with colistin would be suitable unless otherwise contraindicated. All 48 isolates were positive for \textit{bla\textit{OXA-23}}; none was positive for \textit{bla\textit{OXA-24}}, \textit{bla\textit{OXA-58}} or \textit{bla\textit{NDM}}.

Clonality analysis typing revealed the existence of two predominant genotypes (Fig. 1). The first genotype was the most frequent (20 isolates), six of which were isolated from the MICU in 2011. The second most frequent genotype was isolated from ten isolates (after excluding one wrongly included.

sample); five were from the MICU in 2012. This finding suggests the existence of an outbreak in the MICU, but because the isolates were chosen randomly, confirmation of an outbreak cannot be done except after a clonality study of all isolated A. baumannii during the 2 years to determine the isolation of certain genotypes from the MICU.

Discussion

MDR A. baumannii has emerged globally in both community and hospital settings, causing many outbreaks, especially in ICUs [12]. In our study, 28 of 48 patients were from ICUs. Resistance to carbapenems among these isolates left no options for treatment except colistin, which has many adverse effects, including nephrotoxicity and neurotoxicity which affect mainly debilitated persons [13,14]. In HMC, approximately 60% of A. baumannii isolated from clinically significant samples are MDR; in our study, we found 48 MDR A. baumannii clinical isolates which were randomly selected during the period 2011–2012 from isolates stored in the cryobank of HMC as a pilot study. In addition to describing the molecular characterization of carbapenem resistance in A. baumannii, we also studied the genetic relatedness of these isolates. Results of our report will be used to study all MDR A. baumannii isolated in the previous years to describe the magnitude of resistance in this organism and to learn which common genotypes are circulating in Qatar.

All 48 isolates were positive for blaOXA-23. We detected no New Delhi metallo-β-lactamase (NDM) in the studied isolates even though Qatar’s population structure is composed of different nationalities, including many expatriates coming from the Indian subcontinent. Studying all A. baumannii stored in the previous years is expected to reveal the presence of NDM. Our results are comparable with a recent study of A. baumannii which included seven hospitals in the Gulf Cooperation Countries, including eight isolates from Qatar, all of which were positive for blaOXA-23, as well as many other countries in the region, including all isolates from Kuwait, Oman and United Arab Emirates and 90% of isolates from Riyadh, Saudi Arabia; 38% from Bahrain were positive for blaOXA-23 [8].

NDM was detected in many countries in the Middle East in Enterobacteriaceae and A. baumannii, including the United Arab Emirates, Oman, Saudi Arabia and Kuwait [15–18].

By comparing different studies which were conducted in the Middle East (Kuwait, Saudi Arabia, Egypt, Algeria, Yemen), no specific carbapenemase was found to be confined to the region. In Egypt, three acquired class D carbapenemases (blaOXA-23 in 72%, blaOXA-48 in 4%, blaOXA-58 in 20%) were identified among studied carbapenem-resistant A. baumannii strains in two Egyptian centres [19]. In Saudi Arabia, blaOXA-23, blaOXA-24 and blaOXA-58 were detected in 72.5, 45 and 37.5% respectively in isolated A. baumannii strains [20]. blaOXA-23 was detected in Riyadh and the Eastern Province, with 53 and 79.5% respectively among nonsusceptible A. baumannii (A. Ribeiro, paper presented at 22nd European Congress of Clinical Microbiology and Infectious Diseases (ECCMID), 2012) [21].

In the United Arab Emirates, one study found blaOXA-23-like and blaOXA-64-like genes in all three isolates under study [22]. In Abu Dhabi, it was found that the blaOXA-23-like gene was detected in 73.6% of all strains included in the study [23], while the main oxacillinases in Bahrain were blaOXA-40-like, which is a subgroup of the blaOXA-72-like gene (5/8). Found less frequently were the blaOXA-58-like (1/8) and blaOXA-23-like (2/8) genes [24]. A Yemeni study identified three MDR A. baumannii; the blaOXA-51-like gene and the acquired carbapenemase blaOXA-23-like gene were detected in all three strains [25].

Clonality analysis typing revealed high diversity within our isolates, with predominance of two genotypes. The high diversity is explained by the diversity of the population of Qatar. Clonal dissemination was observed in the MICU during 2011–2012; nonclonal spread occurred in whole hospital wards and outpatient clinics.

In 1998, a Qatari study in an ICU in HMC revealed that all A. baumannii were carbapenem susceptible, while another study, performed between 2007 and 2008 on blood culture isolates, found carbapenem resistance in more than one third of the isolated A. baumannii (41.5%). In 2002, an outbreak in a TICU in HMC occurred by carbapenem-resistant A. baumannii which involved 20 patients admitted to the TICU during a 6-month period. A typing study was not performed at that time, but by comparing antibiograms of patient isolates to those isolated from the environment, it was found that all isolates shared the same antibiogram [26–28]. Given the occurrences of MDR A. baumannii in HMC, especially in the MICU, it is clear that stringent infection control measures need to be implemented. Further, studying the occurrence of all A. baumannii in previous years will provide insight into the presence of this organism’s endemicity or epidemicity; there is also a need to screen these wards to compare the environmental clones to those isolated from patients.

In conclusion, studying molecular resistance genes and molecular the clonal relatedness provides insight into the transmission of MDR A. baumannii within HMC. This study has revealed the need to study all A. baumannii isolated in previous years to confirm the occurrence of the MICU outbreak of MDR A. baumannii during the 2011–2012 period and to confirm the presence or absence of other resistance genes, such as NDM or other metallo-β-lactamase resistance genes.
